APPENDIX 4.3 - HRA

Attachment 2

1 ATTACHMENT 2 TO APPENDIX 4.3-HRA: METEOROLOGICAL DATA PROCESSING METHODOLOGIES

1.1 METEOROLOGICAL DATA SELECTION

1.1.1 Meteorological Data

AERMOD requires a meteorological input file to characterize the transport and dispersion of pollutants in the atmosphere. In order to create this input file, surface and upper air meteorological data inputs, along with surface parameter data describing the land use and surface characteristics near the site, are first processed using AERMET, the meteorological preprocessor to AERMOD. The output file generated by AERMET is the meteorological input file required by AERMOD. Details of AERMET and AERMOD meteorological data needs are described in US Environmental Protection Agency (USEPA) guidance documents (USEPA, 2012a, 2012b). This appendix describes the use of onsite surface meteorological data, as well as the selection of representative surface and upper air meteorological data sets for the Site, and the methodology used for processing the meteorological data in AERMET.

1.1.1.1 Selection of Surface Meteorological Data

When characterizing near-field air pollutant dispersion using models such as AERMOD, representative hourly surface meteorological data inputs are required to characterize the atmospheric transport and dispersion in the area to be studied. AERMET, the meteorological preprocessor to AERMOD, requires certain surface meteorological parameters in order to prepare an AERMOD meteorological data input file. The minimum surface meteorological parameters required include wind speed, wind direction, temperature, and cloud cover (USEPA 2012b). Station pressure is also recommended, but is not required for AERMET (USEPA, 2012a).

Two surface meteorological stations were found in the vicinity of the Site: one is the station maintained by the Facility located just south of the western end of the W. Gertrude Avenue (Gertrude station). The other station is a National Climate Data Center (NCDC) station (AWS ID 994036) located on the Refinery Pier just south of Highway 580 (Wharf station). Figure 1 presents the locations of both stations, together with windroses based on data from each station. A comparison of the windroses indicates that the wind conditions between the two stations are generally similar; however, there are a few notable differences. One

difference is that low wind speeds occur more frequently at the Wharf station than at the Gertrude station. In addition, wind blowing from the northwest direction happens more frequently at the Wharf station than at the Gertrude station. The more frequent northwest wind at the Wharf station can be explained by the “channeling” effect of the terrain just north of the Wharf station. Figure 2 presents the two stations overlaid with terrain data downloaded from United States Geological Survey (USGS, 2011), which shows a mountain ridge running from Point San Pablo to south of the Site boundary, separating the two stations. Due to the differences mentioned above, ENVIRON decided that the Gertrude station represents meteorological condition on the north side of the mountain ridge, while the Wharf station represents meteorological condition on the south side of the mountain ridge. Therefore, ENVIRON processed both sets of meteorological data for modeling.

Completeness analysis of these two stations revealed that the Gertrude station meets 90% completeness criteria required by USEPA (USEPA, 2005) for years 2008-2010. However the Wharf station only meets the completeness criteria for the last quarter of 2009 through the first three quarters of 2010. Since both stations are located on the Facility property and are representative of part of the Modernization Project Site, only one year of meteorological data is required for regulatory dispersion modeling (USEPA, 2005). Therefore one year of meteorological data from October 1, 2009 to September 30, 2010 at the Gertrude station were processed. The data include wind speed, wind direction, and surface temperature. In addition, data from the same time period¹ at the Wharf station were processed. The data include wind speed, wind direction, and surface temperature. No data substitution to these two on-site stations were performed.

ENVIRON obtained surface data from the National Climactic Data Center’s (NCDC, 2011) Oakland International Airport (OAK) station.

1.1.1.2 Selection of Upper Air Meteorological Data

AERMET also requires upper air sounding data in order to prepare an AERMOD meteorological data input file (USEPA, 2011a, 2011b). The upper air sounding data are typically only available from NCDC stations and are measurements of various meteorological parameters such as wind speed and direction, temperature, and pressure, usually taken at multiple levels in the atmosphere. Oakland International Airport (OAK) is the only upper air station in Northern

¹ 2008 data at the Wharf station does not meet the 90% complete requirement.

California that NCDC recommends for reliable, complete, and representative upper air data for air dispersion modeling in Northern California.² Thus, upper air data from the OAK was used in AERMET processing for the Site. Station pressure and cloud cover from the OAK station was used to supplement the Gertrude and Pier surface data.

1.2 AERMET DATA PROCESSING METHODS

In addition to the surface and upper air meteorological data discussed previously, surface parameters representing the land use and surface characteristics are required for processing meteorological data in AERMET. The methods used to develop surface parameters for the Site are discussed below.

1.2.1 Determining Surface Parameters using AERSURFACE

Prior to running AERMET, it is necessary to specify the surface parameters to be used. The surface parameters including surface roughness, Albedo, and Bowen ratio are required to compute heat fluxes and stability of the atmosphere (USEPA 2012b). Typically, land use characteristics around both the primary project area and the surface meteorological data collection site shall be evaluated and compared to determine the representativeness of the meteorological station, as recommended by the USEPA (USEPA, 2009, 2012b) and the California Air Resources Board (ARB) Guidelines (ARB, 2006). Because the primary meteorological stations (the Gertrude station and the Wharf station) are located on-site, surface parameters calculated for the meteorological stations are also representative of the Site.

Land cover data for the areas surrounding the on-site meteorological stations (the Gertrude station and the Wharf station) were used with the land cover data processor of AERMOD (i.e., AERSURFACE) to calculate surface parameters.

1.2.2 Land Cover

ENVIRON used the USGS National Land Cover Database (NLCD) maps from 1992 (USGS, 1992). Although the most recent NLCD maps available contain 2006 data, historical aerial maps show that the area around the site did not experience significant changes between 1992 and 2006. Some of the Site's surroundings were somewhat less developed in 1992 than in 2006; however, because less-developed areas are represented by lower surface roughness, the air dispersion

² Personal communication, William Brown of NCDC by telephone to C. Mukai of ENVIRON on May 5, 2006.

model predicts higher (i.e. more conservative) pollutant concentrations because there is reduced turbulence created by the movement of air through the area. Therefore, as a conservative measure, and in an effort to use representative land cover types, ENVIRON used the 1992 NLCD maps published by the USGS for the surface parameter analysis.

1.2.3 AERSURFACE Inputs

ENVIRON followed the USEPA (2013a) recommendations regarding the use of an upwind fetch distance of one kilometer for estimation of the surface roughness length, which corresponds to a circle with a radius of one kilometer surrounding the meteorological station. The recommendation is based on the estimated typical distance required to obtain a new turbulent boundary layer height after a roughness transition (USEPA, 2013).

AERMET accepts as input a table of surface parameters defined according to radial sectors centered at the meteorological station covering segments of wind direction. A maximum of twelve sectors of at least 30 degrees can be chosen based on patterns in the local land use. The number of sectors and the directions included in each are left to the determination of the user. For the both of the on-site meteorological stations, ENVIRON used the AERSURFACE default value of twelve sectors. ENVIRON then specified surface parameters for each sector using default seasonal values that are adjusted for the local climate. For Albedo and Bowen ratio, the same locally-adjusted default seasonal values were applied to the non-sector-specific 10-kilometer by 10-kilometer square area surrounding the each of the meteorological monitoring stations.

Where available and appropriate, the USEPA guidance (USEPA, 2009, 2011b) was followed. However, the USEPA guidance was developed based on nationwide averages. There are instances in which known local characteristics differ from national norms and would impact the methods used to evaluate the surface parameters. This topic is discussed in additional detail below.

1.2.4 Season Assignments and Precipitation Condition

The AERMET User's Guide (USEPA, 2011a) contains tables of values for the surface parameters based on four seasonal vegetative cycles (e.g., 'spring' refers to the period of re-growth after the last frost). AERMET accepts surface parameters for annual, seasonal, or monthly periods. The determination of the appropriate seasonal values for a given period, in addition to the choice of annual, seasonal, or monthly temporal divisions, is left to the user. The decision is particularly important in California (and thus for the Site), which has seasonal weather that is atypical from what is assumed in the User's Guide (USEPA, 2012a) as nationwide averages. For example, default winter season in the User's

Guide assumes a presence of snow cover, while the Site typically does not experience any snow cover at all. To better represent the Site condition, ENVIRON assigned each month a corresponding seasonal category based on the local conditions and the USEPA Guidance, as explained below (USEPA, 2012a). The methodologies for determining the seasons to use and months of each season have been approved by the Bay Area Air Quality Management District (BAAQMD), and have been used in multiple analyses approved by the District (ENVIRON, 2006, 2009).

In addition to defining the months of the seasons at the Site, ENVIRON also evaluated precipitation data in order to select a condition (wet, dry, average) for the Bowen ratio calculation. ENVIRON first examined seasonal precipitation totals from meteorological stations in the vicinity of the Site for the modeling period of interest (January 1, 2008 – December 31, 2010). Precipitation totals were taken from the Western Regional Climate Center (WRCC) Richmond meteorological station (station ID 47414), the closest station to the Site with available precipitation data. Data do not meet the completeness criteria from the WRCC Richmond meteorological station for autumn of 2009 and autumn of 2010; therefore, precipitation totals were also evaluated for the next two closest stations to the Site, - the WRCC Berkeley station (station ID 40693) and the WRCC Oakland Museum station (station ID 46336).

As suggested by the AERSURFACE's User's Guide (USEPA 2013), the precipitation totals for the year of interest were then compared to the 30-year historical precipitation averages measured at the WRCC Richmond meteorological station. If the tabulated values were higher than the 70th-percentile for historical precipitation, a "wet" Bowen ratio condition was selected. If the tabulated values were lower than the 30th-percentile for historical precipitation, a "dry" Bowen ratio condition was selected. Otherwise, an "average" Bowen ratio condition was selected if precipitation was between the 30th and 70th percentile for historical precipitation. Similarly, the condition for autumn of 2009 and autumn of 2010 from the other two stations were compared to their 30-year historical precipitation averages for the corresponding seasons.

1.2.5 AERMET Input

ENVIRON used version 12345 of the USEPA AERMET executable to process the data. As mentioned previously, surface air data and upper air data, together with the calculated surface parameters were combined and processed using AERMET. Two sets of surface meteorological data representing the Gertrude station and the Wharf station were used, with on-site data supplemented by the NCDC surface data from the Oakland International Airport station. Two sets of AERMET runs were conducted, one for the Gertrude station, and one for the Wharf

station. Two output files were generated for each AERMET run: a surface file and a profile file.

1 Attachment 3 to Appendix 4.3-HRA: Super Automated Risk Assessment Database (SARAD) and Comparison to Hotspots Analysis Reporting Program (HARP)

Risk assessments conducted to the standards required by the BAAQMD and OEHHA may involve sizeable data sets in order to thoroughly analyze the impacts from a large project, like the Modernization Project. In the case of the Modernization Project, over 50 TACs are emitted from over 150 different sources associated with the Project, including Refinery Operations and shipping. In addition, during the construction of the Modernization Project, 15 TACs are emitted from the off-road construction equipment and on-road vehicles. In order to carefully analyze impacts on the community, the evaluation was conducted at over 8000 locations in the community. In order to evaluate large data sets some type of database is typically programmed to allow for efficient calculations.

The Hotspots Analysis and Reporting Program (HARP) is a tool that assists with the programmatic requirements of the Air Toxics "Hot Spots" Program. The Air Toxics "Hot Spots" Program has the same risk assessment requirements as does the BAAQMD for CEQA. HARP is a single integrated software package that can be used by the air pollution control and air quality management districts (districts), facility operators, and other parties to promote statewide consistency, efficiency, and cost-effective development of health risk assessments. While HARP is a useful tool, it does not permit the analysis of data sets as large as that required for the Modernization Project. In addition, HARP does not allow the evaluation of time-changing activities, such as construction, which operate only 10 hours in a 24 hour day. Finally, HARP does not incorporate the childhood cancer sensitivity factors required for use by the BAAQMD.

In order to analyze the large dataset required for the Modernization Project, ENVIRON, the City's Consultants, programmed a Microsoft Access 2010 database to mimic the functions of HARP for the inhalation pathway. In addition, another set of databases were developed to evaluate the impact of the TAC emissions through the non-inhalation pathways, referred to as multi-pathway analysis. It was then concluded that the cancer risks and non-cancer hazards associated with the multi-pathway exposures are small compared to the CEQA thresholds for risks and non-cancer chronic hazards. The resulting programmed Microsoft Access database used to mimic the inhalation pathway of HARP is called the

Super Automated Risk Assessment Database, or SARAD. The City's Consultants, have used forms of this database for years to analyze risks for permitting projects and CEQA projects within the jurisdiction of the BAAQMD. The Microsoft Access database used for the multi-pathway analysis then scaled the inhalation risks and chronic hazards by the multi-pathway scaling factors derived from HARP version 1.4f to estimate risks and chronic hazards in SARAD for each multi-pathway chemical.

This attachment describes in detail how SARAD works, and describes the evaluation conducted to show equivalence between SARAD and HARP to confirm that the results from SARAD are the same as would result if HARP could be used for this evaluation.

Because the SARADs used for the construction and operational impact analyses have the same general structure, and function the same way, this attachment describes the methods used for both analyses.

1.1 Introduction

SARAD was used to perform calculations for the ambient air quality (AAQ) health risk assessment (HRA) of potential toxic air containments (TAC) emissions from construction of the Chevron Modernization Project, and incremental TAC emissions from the Facility operations resulting from the Modernization Project. SARAD was also used to estimate incremental $PM_{2.5}$ concentrations from construction and operation of the Modernization Project.

The databases allow for the easy calculation of health risks and $PM_{2.5}$ concentrations by performing a series of calculations using several data sources. As further discussed in Appendices 4.3-HRA and 4.3-CHRA, estimating health risk requires data such as: airborne concentrations of TACs; toxicity information on TACs; and exposure information for populations of interest. Airborne concentrations of TACs and $PM_{2.5}$ are estimated from information on how chemicals move in the air (air dispersion) from each emissions source, and the quantity of TAC and $PM_{2.5}$ emissions from each emissions source.

Figure A4.3-HRA-Attachment 3.1 contains an illustration of how health risk is estimated using SARAD. SARAD estimates human health risks due to chemical exposures at specific locations (i.e., receptors) for specific population groups (e.g., adult residents, adult workers) as a result of air emissions from many emission sources. At a given receptor (e.g., adult resident 1), the air concentration of a compound (e.g., benzene) is the sum of emissions from many sources, for example a stack and several tanks. Similarly, the health risk is the sum of health impacts from a number of chemicals, say, benzene and diesel particulate matter

(DPM). It also depends on the concentration of each compound as well as amount that each type of exposed population breathes at a location in a day. For example, a resident breathes air throughout the day, whereas a worker only breathes air at a work location during working hours. If there is more than one compound that is contributing to the health risk at a given receptor, then the health risk at that receptor is estimated as the sum of the health risks from all compounds estimated to be in the air near that receptor and have a similar adverse health effect. For example, to estimate cancer risk at a specific receptor, the health risks from all carcinogens in the air near that receptor are summed together. To estimate non-cancer risk, the health risks from all compounds that affect a similar target organ are summed together.

FIGURE A4.3-HRA-ATTACHMENT 3.1 CONCEPTUAL ILLUSTRATION OF SARAD CALCULATIONS

The remainder of this attachment provides a description of SARAD, including an overview of the database structure as well as the methods that are used in the calculation of health risks. As further described in Appendices 4.3-HRA and 4.3-CHRA, for this HRA ENVIRON estimated cancer risks, chronic non-cancer hazard indices, acute non-cancer hazard indices, and $PM_{2.5}$ concentrations for all receptor types.¹

As discussed above, SARAD was used to calculate cancer risks and chronic non-cancer hazards through the inhalation pathway only and then for all pathways using a multipathway factor. It was then concluded that the cancer risks and non-cancer hazards associated with the multi-pathway exposures are small compared to the CEQA threshold for risks and non-cancer chronic hazards. The details of the SARAD configuration used for the multi-pathway analysis is described at the end of this attachment.

1.2 Structure of SARAD for Construction Impacts

As discussed above, health risk is estimated based on contributions of numerous TACs from a variety of emission sources. For the construction portion of the HRA as described in Appendix 4.3-CHRA, the two main categories of emission sources include off-road equipment and on-road mobile emission sources. Air concentrations of TACs and $PM_{2.5}$, as well as cancer risks and non-cancer hazards from these emissions categories were estimated in separate databases. Due to the large number of on-road emission sources included in this HRA, air concentrations, cancer risks, and non-cancer hazards from on-road emission sources were calculated in two separate databases, one used to calculate the maximum one-hour concentrations for acute effects and one used to calculate the average annual concentrations for chronic effects. These air concentrations, cancer risks, and non-cancer hazards were then combined in a different database to calculate the overall health risks from construction activities.

1.3 Structure of SARAD for Operational Impacts

For the operation portion of the HRA as described in Appendix 4.3-HRA, the three main categories of emission sources include Refinery Operations, shipping, and trucking. Air concentrations of TACs and $PM_{2.5}$, as well as cancer risks and non-cancer hazards from each of these emission categories were estimated in separate databases. These air concentrations, cancer risks, and non-cancer

¹ Cancer risks were estimated for 70-year residents and worker receptors, while chronic and acute non-cancer hazard and $PM_{2.5}$ concentrations were evaluated for all types of receptors.

hazards were then combined in a different database to calculate the overall health risks from operational activities. A separate set of databases was used for each Project scenario evaluated for Refinery Operations and Shipping. All cases were evaluated in one SARAD database for trucking.

1.4 Database Tables Used in Health Risk Calculations

Each SARAD database consists of six input tables. Four tables contain air emissions and modeling information and two tables contain human health risk assessment data. Figure A4.3-HRA-Attachment 3.2 summarizes the relationship between the input tables in the database. Table A4.3-HRA-Attachment 3.1 provides definitions of select column names and data entries. All tables used in the database are described below.

FIGURE A4.3-HRA-ATTACHMENT 3.2 INPUT TABLES USED IN HEALTH RISK DATABASES

TABLE A4.3-HRA-ATTACHMENT 3.1 DEFINITIONS OF SELECT COLUMN NAMES IN DATABASE TABLES

Table Name	Column Name/Data Entry	Definition
tblReceptors	Receptor_ID	ENVIRON-assigned receptor ID
	UTMx	X-coordinate (m)
	UTMy	Y-coordinate (m)
	Population	Identifies population-type of receptor (e.g., resident, worker, school child)
tblDispersionFactors	Annual_Dispersion_Factor	Annual dispersion factor
	Hourly_Dispersion_Factor	Maximum hourly dispersion factor
	SrcGrp	ENVIRON-assigned source ID
tblEmissions	Emission_Type	Description of emissions (e.g., annual, 1-hour)
	Emissions	Emission rate
	Unit	Units for emission rate (g/s)
	Fuel	Type of fuel (e.g., diesel)
	Pollutant	Compound associated with emission rate (e.g., TOG)
	Year	Year when emissions are released
	Spec_profile_ID	Speciation profile associated with a specific emission source or fuel
tblSpeciation	Chemical	Chemical
	CAS	Chemical Abstract Service registry number
	Quantity	Fraction of emissions attributable to specified chemical
tblExposure	IFinh	Intake factor for specified receptor type (m3/kg-day)

Table Name	Column Name/Data Entry	Definition
	DBR	Daily Breathing Rate for specified receptor type (L/kg-day)
	HBR	Hourly Breathing Rate for specified receptor type (L/kg-hour)
	BW	Body weight (kg)
	ET	Exposure time (hours/24-hours)
	EF	Exposure Frequency for specified receptor type (days/year)
	ED	Exposure Duration for specified receptor type (years)
	AT	Averaging Time (days)
	MAF	Modeling adjustment factor (unitless)
	ASF/CRAF	Cancer risk adjustment factor (unitless)
tblToxicity	CPF	Cancer potency factor (mg/kg-day) ⁻¹
	AcuteREL	Acute Reference Exposure Level (µg/m ³)
	ChronREL	Chronic Reference Exposure Level (µg/m ³)
tblToxicity	Multi-pathway Chemical	Marks whether a TAC is a multi-pathway chemical
	Cancer Multi-pathway Factor	Scaling factor to be multiplied to inhalation cancer risk to yield non-inhalation cancer risk
	Chronic HQ Multi-pathway Factor	Scaling factor to be multiplied to inhalation chronic HQ to yield non-inhalation chronic HQ

The purpose of the figure and the table above is to illustrate the content of the SARAD input files. The inputs in the SARADs used for this analysis generally follow the structure of the six input files presented above. In addition, the emission rates in the SARADs for Refinery Operations are incremental emissions (i.e., Project case minus Baseline emissions) while the emissions rates in the trucking and shipping SARADs include Project emissions and baseline emissions separately. Incremental emissions were used to simplify the SARADs for Refinery Operations. Refinery Operations contains hundreds of emission sources, and emissions from most of these sources are not changing as a result of the Modernization Project. Because these emissions from these sources are not changing as a result of the Modernization Project, there is also no change in risk and non-cancer hazards resulting from these sources. Thus, to reduce the complexity of the Refinery Operations SARAD databases, Refinery Operations emissions sources that are not impacted by the Modernization Project were not included in the incremental emissions table. Additional details on each of these tables are presented below.

1.4.1 Air Emission and Modeling Tables

The information presented in the following tables includes emissions and air dispersion modeling information used to calculate health impacts in SARAD.

“tblReceptors” Table

This table relates X- and Y- coordinates to potentially exposed populations, as shown in Table A4.3-HRA-Attachment 3.2. The table contains Universal Transverse Mercator (UTMx and UTM_y) coordinates in meters (m) and receptor identification numbers for tracking purposes (“Receptor_ID” column). The potentially exposed populations (“Population”) considered in this HRA, include residents (children and adults), school children, daycare children, community center children and adults, patients (children and adults), recreational facility children and adults, and adult workers.

TABLE A4.3-HRA-ATTACHMENT 3.2 EXAMPLE ENTRIES IN RECEPTOR TABLE

Receptor_ID	UTMx	UTMy	Population
R0001	549000	4194000	Worker
R0053	559400	4194000	Resident
R6780	554439	4197648	School Child

“tblDispersion Factors” Table

This table lists the annual average (see “Annual_Dispersion_Factor” column) and maximum 1-hour average (see “Hourly_Dispersion_Factor” column) dispersion coefficients calculated for each modeled source (see “SrcGrp” column) for each receptor location listed in the “Receptor_ID” column (see Table A4.3-HRA-Attachment 3.3 below for example of table). As

described in Appendix 4.3-HRA and A4.3-CHRA, a dispersion coefficient is the source-specific concentration estimated by the air dispersion model for a unit emission rate (i.e., 1 gram per second). The dispersion coefficients in this table are in units of micrograms per cubic meter over grams per second ($(\mu\text{g}/\text{m}^3)/(\text{g}/\text{s})$) and are used in conjunction with TAC and $\text{PM}_{2.5}$ emission rates to estimate ambient concentrations.

TABLE A4.3-HRA-ATTACHMENT 3.3 EXAMPLE ENTRIES IN DISPERSION TABLE

Receptor_ID	Annual_Dispersion_Factor	Hourly_Dispersion_Factor	SrcGrp
R0001	0.02227	16.14874	EXISH2
R0001	0.02698	12.77279	SRU

“tblEmissions” Table

This table lists chemical-specific or compound-specific emission rates (see “Emissions” column) for each source evaluated in this HRA. For the Refinery Operations SARAD databases, the emission rates were chemical-specific. For the construction, shipping, and operational trucking SARAD databases, some of the emission rates in this table were for a mixture of either total organic gases or reactive organic gases, in which case the speciation profile table described below provides the chemical breakdown of these mixtures. An example entry is shown in Table A4.3-HRA-Attachment 3.4. The “Source” column identifies the emission source from which the emissions are released. Emission rates are in units of grams per second (g/s). If a source burns fuel, the fuel type is specified under the “Fuel” field, when applicable. The year when the emissions are applicable is specified under the “Year” field. The “Year” field is relevant for the construction HRA, where the construction sources changed by year. The “Spec_Profile_ID” column identifies the speciation profile that is applicable for each source.

TABLE A4.3-HRA-ATTACHMENT 3.4 EXAMPLE ENTRIES IN EMISSION PROFILE TABLE

Emission_Type	Emissions	Unit	Fuel	Pollutant	Source	Year	Spec_Profile_ID
Annual	1.82E-02	g/s	Diesel	$\text{PM}_{2.5}$	EXISH2	2016	3
Annual	1.80E-02	g/s	Diesel	DPM	SRU	2014	428

“tblSpeciation” Table

This table contains the chemical breakdown for each speciation profile. For each speciation profile (“Spec_profile_ID”), the quantity of each chemical is expressed along with the chemical abstract service (“CAS”) registry number, a unique identifier for each chemical. In the example table below, acrolein represents approximately 0.13% of the gasoline exhaust total organic gas (TOG) profile.

TABLE A4.3-HRA-ATTACHMENT 3.5 EXAMPLE ENTRY IN SPECIATION TABLE

Chemical	Fuel	Spec_profile_ID	CAS	Quantity
Acrolein	Gasoline Exhaust TOG	5	107028	0.0013
Diesel PM	Diesel	428	9901	1

1.4.2 Human Health Calculation Database Tables

The dose estimated for each exposure pathway is a function of the concentration of a chemical and the intake of that chemical. Similar to the emissions and air modeling tables presented above, SARAD also has a couple of tables that are used as inputs in the calculation of health risks. The two main input tables used to calculate human health risk involve exposure parameters and chemical toxicity data. Additional details on each of these tables are provided below.

“tblExposure” Table

The “exposure” table contains the exposure assumptions used to estimate human health risks for the population types (“Population”) considered in this HRA. The inhalation intake factor (“IF_{Inh}”) is based on the daily breathing rate (“DBR”), exposure time (“ET”), exposure frequency (“EF”), exposure duration (“ED”), and the overall averaging time (“AT”). Table A4.3-HRA Attachment 3.6 presents example exposure parameters used in the database.

TABLE A4.3-HRA-ATTACHMENT 3.6 EXAMPLE ENTRY IN EXPOSURE TABLE

Population	Receptor_type	Year	IF _{Inh}	DBR	HBR ¹	BW ¹	ET	EF	ED	AT	MAF	CRAF
Community Center Child	Community Center Child	2008	0.078	581			10	245	1	25550	3.36	5.2
Recreational User	Recreational Adult	2014			1.74	63	1	52	1	25550	3.36	1.7
Resident	Resident	All	0.4923	302			24	350	70	25550	1	1.7

Note: The exposure assumption for recreational user is not available in the BAAQMD guidance (2010) or the OEHHHA guidance (2003). As a result, the exposure assumption (i.e., hourly breathing rate, and body weight) from the USEPA Exposure Handbook (2011) was used. The USEPA Exposure Handbook is available at <http://www.epa.gov/ncea/>.

As further discussed in Appendix 4.3-HRA, the equation used to calculate the inhalation intake factor (IF_{inh}), is as follows:

$$IF_{inh} = \frac{DBR \times ET \times EF \times ED \times CF}{AT}$$

Where:

IF_{inh}	=	Intake Factor for Inhalation ($m^3/kg\text{-day}$)
DBR	=	Daily Breathing Rate ($L/kg\text{-day}$)
ET	=	Exposure Time (hours/24 hours)
EF	=	Exposure Frequency (days/year)
ED	=	Exposure Duration (years)
AT	=	Averaging Time (days)
CF	=	Conversion Factor ($0.001\ m^3/L$)

The model adjustment factor (MAF) and cancer risk adjustment factor (CRAF) are further discussed in Appendix 4.3-HRA and in the sections below.

“tblToxicity” Table

The “tblToxicity” table contains the chemical-specific toxicity values used to estimate human health risks in this HRA. As shown in Table A4.3-HRA-Attachment 3.7, the toxicity inputs include the cancer potency factor (CPF) (“CPF” column), acute REL (“AcuteREL” column) and chronic REL (“ChronREL” column).

The CPF is expressed in units of (milligram [mg]/kilogram-day [kg-day])⁻¹. The acute REL and chronic REL are expressed in units of g/m^3 .

In addition, the toxicity table also has a column (“Multi-path Chemical” column) that marks the whether a chemical is a multi-pathway chemical. The chemicals that are emitted from the refinery and shipping activities at the Facility and that are multi-pathway chemicals are: arsenic, beryllium, cadmium, chromium (VI), lead, mercury, nickel, and polycyclic aromatic hydrocarbons (PAHs) including benzo(a)pyrene, b(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene. In the last two columns of the table, the multi-pathway scaling factors derived from HARP version 1.7f for non-inhalation cancer risk and Chronic HQ calculation are provided. The methodology used to derive these scaling factors are described in Appendix 4.3-HRA.

TABLE A4.3-HRA-ATTACHMENT 3.7 EXAMPLE ENTRY IN TOXICITY TABLE

Chemical	CAS	CPF	AcuteREL	ChronREL	Multi-path Chemical?	Cancer Multi-path Factor	Chronic HQ Multi-path Factor
Arsenic	7440382	12	0.2	0.015	Yes	3.76	39.0
1,3-Butadiene	106990	6.00E-01	6.60E+02	2.00E+00			
Diesel PM	9901	1.10E+00		5.00E+00			

1.5 Risk Characterization Calculations for Inhalation Pathway

As discussed in Appendix 4.3-HRA, this HRA includes estimates of cancer risk as well as an evaluation of acute and chronic non-cancer health effects. This section includes a discussion of how SARAD estimates airborne concentrations of TACs based on the emissions and modeling inputs described earlier. This section also includes a discussion of how SARAD estimates cancer and non-cancer risks using the calculated airborne concentrations of TACs and the risk inputs described earlier.

1.5.1 Calculation of Airborne Concentrations

To calculate the overall, chemical-specific airborne concentrations resulting from all emission sources for each receptor location, emission rates from the “tblEmissions” table and dispersion coefficients from the “tblDispersionFactors” table were used at each receptor location using the following formula:

$$C_i = \sum_{source=1}^{#sources} [ER * (\chi / Q)]_{source}$$

Where:

C_i	=	Air Concentration of Chemical i ($\mu\text{g}/\text{m}^3$)
ER	=	Source-Specific Emission Rate (from “tblEmissions” table) (g/s)
(χ/Q)	=	Source-Specific Dispersion Coefficient (from “tblDispersion Factors” table) ($\mu\text{g}/\text{m}^3$ per g/s)

In the above formula, the chemical specific emission rate for each source is multiplied by the dispersion factor for each source, and then this product is summed across all sources emitting that chemical. Annual average ambient air concentrations were calculated with this formula by using annual average emission rates and dispersion coefficients, whereas maximum 1-hour ambient air concentrations were calculated with this formula by using 1-hour average emission rates and maximum 1-hour dispersion coefficients.

As discussed in Appendix A4.3-HRA, Cal/EPA recommends applying an adjustment factor to air concentrations based on a continuous averaging period (i.e., 24 hours per day, 365 days per year) when the following three things are true (1) the actual exposure occurs for less than 24 hours per day and/or less than one year, (2) emission activities occur for less than 24 hours per day and/or less than one year, and (3) exposures are entirely or partially concurrent with emitting activities (OEHHA, 2013). The model averages the emissions over 24 hour per day over a year. The modeling adjustment factor is applied to the modeled annual average concentrations from the Modernization Project construction to reflect the fact that the actual exposure concentration the receptor is exposed to is higher than the average annual concentration. Because operational activities occur at any time of day, a constant emission rate for 24 hours per day, 7 days per week was assumed for all operational sources. Therefore, no MAF was required for any receptor type for operation.

The exposure point concentrations for receptors requiring a model adjustment factor (i.e., daycare child and school child) were calculated using the following equation for construction:

$$C_i = C_{i,annual} \times MAF$$

Where:

C_i	=	Exposure Point Concentration of Chemical _i ($\mu\text{g}/\text{m}^3$)
$C_{i,annual}$	=	Annual Average Concentration of Chemical _i ($\mu\text{g}/\text{m}^3$)
MAF	=	Modeling adjustment factor (unitless)

1.5.2 Calculation of Cancer Risk

The equation used to calculate the potential excess lifetime cancer risk for the inhalation pathway is as follows:

$$\text{Risk}_{inh} = \sum C_i \times CF \times IF_{inh} \times CPF_i \times CRAF$$

Where:

Risk_{inh}	=	Cancer Risk; the incremental probability of an individual developing cancer as a result of inhalation exposure to a particular potential carcinogen (unitless)
C_i	=	Annual Average Air Concentration for Chemical _i ($\mu\text{g}/\text{m}^3$)
CF	=	Conversion Factor ($\text{mg}/\mu\text{g}$)
IF_{inh}	=	Intake Factor for Inhalation ($\text{m}^3/\text{kg}\cdot\text{day}$)
CPF_i	=	Cancer Potency Factor for Chemical _i ($\text{mg chemical}/\text{kg body weight}\cdot\text{day}$) ⁻¹

CRAF = Cancer Risk Adjustment Factor (unitless)

1.5.3 Calculation of Chronic Noncancer Hazard Quotient/Indices

The equations used to calculate the chemical-specific HQs and the overall HI are:

$$\text{Chronic HQ}_i = C_i / \text{cREL}_i$$

$$\text{Chronic HI} = \sum \text{HQ}_i$$

Where:

Chronic HQ _i	=	Chronic Hazard Quotient for Chemical _i (unitless)
Chronic HI	=	Hazard Index (unitless)
C _i	=	Annual Average Air Concentration for Chemical _i (µg/m ³)
cREL _i	=	Chronic Non-cancer Reference Exposure Level for Chemical _i (µg/m ³)

1.5.4 Calculation of Acute Noncancer Hazard Quotient/Indices

The equations used to calculate the chemical-specific HQs and the overall HI are:

$$\text{Acute HQ}_i = C_i / \text{aREL}_i$$

$$\text{Acute HI} = \sum \text{HQ}_i$$

Where:

Acute HQ _i	=	Acute Hazard Quotient for Chemical _i (unitless)
Acute HI	=	Hazard Index (unitless)
C _i	=	1-hour Maximum Air Concentration for Chemical _i (µg/m ³)
aREL _i	=	Acute Non-cancer Reference Exposure Level for Chemical _i (µg/m ³)

1.5.5 Database Queries

A series of queries used to summarize the cancer and non-cancer risks for inhalation pathway in this HRA are as follows:

- **qryConcentration** – Calculates annual-average and maximum hourly average concentrations for each TAC at each receptor. Results are placed in the “tblConcentrations” table.
- **qryConcentration-Annual PM_{2.5}** – Calculates annual-average concentrations of PM_{2.5} at each receptor. Results are placed in the “tblConcentrations_Annual PM_{2.5}” table.

- **qryRiskSum** – Calculates the total cancer risk at each receptor. Results are placed in the “tblRiskSum” table.
- **qryChronicMaxHI** – Calculates the maximum chronic HI at each receptor. Results are placed in the “tblChronicHIMax” table.
- **qryAcuteMaxHI** – Calculates the maximum acute HI at each receptor. Results are placed in the “tblAcuteHIMax” table.

1.6 Risk Characterization Calculations for Non-inhalation Pathway

As mentioned above, among the TACs evaluated for the inhalation cancer risk and chronic HQ, some are multi-pathway chemicals. The chemicals that are emitted from the refinery and shipping activities at the Facility and that are multi-pathway chemicals are: arsenic, beryllium, cadmium, chromium (VI), lead, mercury, nickel, and polycyclic aromatic hydrocarbons (PAHs) including benzo(a)pyrene, b(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene.

The HARP version 1.4f was used to generate multi-pathway scaling factors. These factors were then used to scale the inhalation risks and HQs calculated in SARADs for the multi-pathway chemicals to estimate cancer risks and non-cancer chronic hazards from the multi-pathway exposures. Consistent with the recommendations in the OEHHA Hot Spots Guidance for conducting a multi-pathway analysis, a 70 year resident was conservatively assumed to be exposed to Facility emissions via inhalation, dermal contact with soil, incidental ingestion of soil, ingestion of homegrown produce, and ingestion of mother’s milk. Using the multi-pathway generated for a 70-year resident for worker receptors yielded conservative non-inhalation cancer risks at these receptors.

To generate the cancer risk multi-pathway scaling factors, the derived (adjusted) method and default exposure settings for a 70-year resident as recommended in the OEHHA Hot Spots Guidance and District HRSA Guidelines (BAAQMD 2010) were used in HARP. This receptor population represents the most conservative exposures among all receptor populations evaluated for the Project. ENVIRON conducted two sets of analysis in HARP to calculate cancer risks for each of the multi-pathway chemicals for 1) inhalation pathway only, and 2) all non-inhalation pathways identified above. The methodologies and equations used in HARP to estimate chemical concentrations in each medium, doses and cancer risks for each exposure pathway are consistent with the recommendations in the Hot Spots Guidance. The cancer risk multi-pathway scaling factors for each of the multi-pathway chemicals were then derived based on cancer risk results from the two sets of analysis using the following equation:

$$\text{Cancer Risk Multipathway Factors} = \frac{\text{All Pathway Risk} - \text{Inhalation Cancer Risk}}{\text{Inhalation Cancer Risk}}$$

As shown in the equation above, because the inhalation pathway risk is subtracted from the all pathway risk, the cancer risk multi-pathway scaling factor derived from this method does not reflect the scaling between the inhalation pathway risk and the all pathway risk. Instead the scaling factor reflects the scaling between the inhalation pathway risk and the non-inhalation multi-pathway risk.

Similarly, to generate the non-cancer chronic HQ multi-pathway scaling factors, the derived (OEHHA) method and default exposure settings for a resident as recommended in the OEHHA Hot Spots Guidance were used in HARP. ENVIRON conducted two sets of analysis in HARP to calculate the non-cancer chronic HQs for each of the multi-pathway chemicals for 1) inhalation pathway only, and 2) all non-inhalation pathways identified above. The equations used in HARP to estimate chemical concentrations in each medium, doses and non-cancer hazards for each exposure pathway are consistent with the methodology recommended in the Hot Spots Guidance. The chronic HQ multi-pathway scaling factors for each of the multi-pathway chemicals were then derived using the maximum all-pathway chronic HQ among all target organs over the maximum inhalation chronic HQ among all target organs using the following equation:

$$\text{Chronic HQ Multipathway Factors} = \frac{\text{Max All Pathway Chronic HQ} - \text{Inhalation Max Chronic HQ}}{\text{Inhalation Chronic HQ}}$$

As shown in the equation above, because the maximum inhalation pathway chronic HQ is subtracted from the all pathway maximum chronic HQ, the chronic HQ multi-pathway scaling factor derived from this method does not reflect the scaling between the maximum inhalation pathway chronic HQ and the maximum all pathway chronic HQ. Instead the scaling factor reflects the scaling between the maximum inhalation pathway chronic HQ and the maximum non-inhalation multi-pathway chronic HQ.

As mentioned in section 1.4.2 above, these scaling factors are contained in the toxicity table of the individual refinery and shipping SARADs for each of the multi-pathway chemical. The scaling factors are also presented Table A4.3-HRA-6 and below.

TABLE A4.3-HRA-ATTACHMENT 3.8 HARP-CALCULATED MULTIPATH SCALING FACTORS

Chemical	CAS	Cancer Risk Multi-Pathway Scaling Factor	Chronic HQ Multi-Pathway Scaling Factor
Arsenic	7440-38-2	3.76	39
Benzo(a)anthracene	56-55-3	28.85	--
Benzo(a)pyrene	50-32-8	28.85	--
Benzo(b)fluoranthene	205-99-2	28.85	--
Benzo(k)fluoranthene	207-08-9	28.85	--
Cadmium	7440-43-9	--	0.494
Chromium (hex)	18540-29-9	0.01	--
Chrysene	218-01-9	28.85	--
Dibenz(a,h)anthracene	53-70-3	9.33	--
Indeno(1,2,3-cd)pyrene	193-39-5	28.85	--
Lead compounds	7439-92-1	3.28	--
Mercury Compounds	7439-97-6	--	5.667

The derived “cancer risk multi-pathway scaling factors” and the “chronic HQ multi-pathway scaling factors” were then imported to a separate multi-pathway SARAD database to estimate cancer risks and chronic HQs for the non-inhalation multi-pathway exposures by applying these scaling factors to the calculated inhalation risks and chronic HQs in the SARADs for each multi-pathway chemical accordingly using the following equation:

$$\text{Multipathway Cancer Risk} = \text{Inhalation Cancer Risk} \times \text{Cancer Risk Multipathway Scaling Factor}$$

$$\text{Multipathway Chronic HQ} = \text{Inhalation Chronic HQ} \times \text{Chronic HQ Multipathway Scaling Factor}$$

1.6.1 Database Queries

The series of queries used to summarize the cancer and non-cancer risks for non-inhalation pathway in this HRA are as follows:

- **qryMake tblCancerRisk_by Chem_multi-path** – Calculates the non-inhalation cancer risk at each receptor for each multi-pathway chemical. Results are placed in the “tblCancerRisk_by chem_multi-path” table.
- **qryMake tblMulti-path Cancer Risk_Total** – Sums the non-inhalation cancer risk for each multi-pathway chemical at each receptor in “tblCancerRisk_by chem_multi-path” table. Results are placed in the “tblMulti-path Cancer Risk_Total” table.

- **qryMake tblChronic HI_by Chem_multi-path** – Calculates the non-inhalation chronic HQ at each receptor for each multi-pathway chemical. Results are placed in the “tblChronic HQ_by chem_multi-path” table.
- **qryMake tblMulti-path Chronic HI_Total** – Sums the non-inhalation chronic HQ for each multi-pathway chemical at each receptor in “tblChronic HI_by chem_multi-path” table. Results are placed in the “tblMulti-path Chronic HQ_Total” table.

These four queries are repeated in the individual shipping and refinery databases for the non-inhalation multi-pathway calculation. Then another database combines the non-inhalation multi-pathway cancer risk and chronic HI from shipping and refinery and calculates total non-inhalation multi-pathway cancer risk and chronic HI from the operations.

1.7 Equivalency between SARAD and Hotspots Analysis Reporting Program (HARP)

ENVIRON evaluated the health impact due to emissions from the construction and operation activities from the facility on the surrounding communities through the inhalation pathway using SARAD. As mentioned above, SARAD was developed in accordance with methodologies recommended by OEHHA Hot Spots Guidance (OEHHA 2003) and BAAQMD CEQA guidelines (BAAQMD 2012). To verify to BAAQMD that the SARAD follows the methodologies that are in compliant with the regulatory requirements, an analysis was conducted to compare the results calculated using SARAD with the results calculated in HARP using the same exposure assumptions, toxicity information, source and emissions information, and air dispersion factors (χ/Q). HARP is a software program developed by Cal/EPA Air Resource Board (ARB) to assist with the programmatic requirements of the Air Toxics “Hot Spots” Program. It combines the emission inventory database, facility prioritization, air dispersion modeling, and risk assessment analysis into one computer software package. In this analysis, ENVIRON used HARP on-ramp to import the previously modeled site-specific source information, TAC emissions, and dispersion factors and converted them into standard input files that are required by HARP. Then the risk analysis module in HARP was used to conduct the cancer risk and chronic HI calculations based on the same default exposure assumptions and toxicity values recommended by OEHHA and BAAQMD as what was used in SARAD for shipping. In order to focus the comparison, ENVIRON identified the chemical (diesel particulate matter [DPM]) and top five source groups (i.e. mntug, SB_TUG, y_tug, x_tug, and mnbrg) that contribute the most to the cancer risk at the maximally exposed individual resident receptor (MEIR) in the shipping evaluation. Each of the five source groups was analyzed separately in HARP and compared with the cancer risk results calculated using SARAD. This analysis was conducted in the following three steps as described below:

In the first step, HARP On-Ramp was used to import and convert the AERMOD input and output files and emissions data to create a source file (*.SRC), a chemical-specific emissions file (*.EMS) for each source group, and a “ χ/Q ” file that includes the dispersion factors and receptor

location information (*.XOQ) that are required by HARP to conduct the health impact analysis. ENVIRON input the name and location for each of the source groups being analyzed in separate HARP On-Ramp runs. DPM emissions data for each source group was entered into HARP On-Ramp for their individual runs. Consistent with the approach used in the shipping evaluation with SARADs, ENVIRON used 70-year ASF-weighted DPM emissions for the cancer risk analysis for a 70-year resident (BAAQMD 2010), and un-weighted DPM emissions for the non-cancer chronic hazard analysis. AERMOD output files (i.e., plot files which present dispersion factors by source group by receptor location) were then uploaded to HARP On-Ramp. The AERMOD output files provide HARP On-Ramp with the dispersion modeling results and indicate the location of receptors in relation to the sources that were entered previously.

In the second step, the input files generated by HARP On-Ramp (*.SRC, *.EMS, and *.XOQ) were uploaded to HARP, exposure parameters were selected that match the parameters assumed in the shipping evaluation with SARAD for a 70-year resident. In this analysis, exposure settings under the OEHHA Derived (Adjusted) method which assumes the default residential exposure assumptions for a resident in the Hot Spot Guidance with the 80th percentile daily breathing rate were used to calculate the cancer risk for a 70-year resident through the inhalation pathway only at the MEIR location. The derived (OEHHA) method was used to calculate the non-cancer chronic HI through the inhalation pathway only at the same location.

In the third step, the HARP-calculated inhalation risks and chronic hazards for each source group were then compared to those calculated in the shipping evaluation with SARAD. As shown in the tables below, the cancer risks and non-cancer chronic HI calculated in the shipping SARADs for the five source groups that contribute the most to total cancer risk and chronic HI for DPM at the MEIR location were equivalent to the cancer risk and chronic hazards calculated in HARP for those source groups for DPM at the same location. Because in both HARP and SARADs the cancer risk and noncancer hazard calculations are conducted the same way for each chemical, each receptor, and each source group, this comparison demonstrates that the SARADs follow the HRA methodologies recommended by OEHHA and BAAQMD for conducting risk assessment and produce risk analysis results equivalent to HARP analysis results for the inhalation pathway.

TABLE A4.3-HRA-ATTACHMENT 3.9 COMPARISON OF ENVIRON-CALCULATED AND HARP-CALCULATED RESULTS CANCER RISK DUE TO EXPOSURE TO DPM EMISSIONS AT MEIR (R7013)

Source Group	ENVIRON-Calculated Risk (in a million)	HARP-Calculated Risk (in a million)
Mntug	20	20
sb_tug	18	18

y_tug	9.2	9.2
x_tug	8.9	8.9
Mnbrg	4.2	4.2

TABLE A4.3-HRA-ATTACHMENT 3.10 COMPARISON OF ENVIRON-CALCULATED AND HARP-CALCULATED RESULTS CHRONIC HI DUE TO EXPOSURE TO DPM EMISSIONS AT MEIR (R7013)²

Source Group	ENVIRON-Calculated Chronic HI	HARP-Calculated Chronic HI
mntug	0.0094	0.0094
SB_TUG	0.0079	0.0079
y_tug	0.0044	0.0044
x_tug	0.0043	0.0043
mnbrg	0.0028	0.0028

An example of the HARP runs used to show equivalence are presented in Attachments 5 and 6. Attachment 5 provides an example of a HARP input and output file for the equivalency test. Attachment 6 provides the HARP input and output files for multi-pathway scaling factors.

The above comparison demonstrates that the SARADs follow the HRA methodologies recommended by OEHHA and BAAQMD for conducting risk assessment and produce risk analysis results equivalent to HARP analysis results for the inhalation pathway. In addition, as discussed in section 1.6, the multi-pathway scaling factors for cancer risk and chronic HQ were derived from HARP version 1.7f using default residential exposure settings for a 70-year resident as recommended in the OEHHA Hot Spots Guidance and District HRSA Guidelines (BAAQMD 2010). Because both inputs (cancer risk and chronic HQ for inhalation pathway, and the corresponding multi-pathway scaling factors) follow the HRA methodologies recommended by OEHHA and BAAQMD for conducting risk assessment and/or use HARP directly, the multi-pathway analysis will produce results equivalent to HARP analysis results for the non-inhalation pathway.

² This location is the cancer risk MEIR rather than the chronic HI MEIR. However because in both HARP and SARAD the cancer risk and noncancer hazard calculations are conducted the same way for each chemical, each receptor, and each source group, this comparison still demonstrates that SARAD follows the HRA methodologies recommended by OEHHA and BAAQMD for conducting risk assessment and produce risk analysis results equivalent to HARP analysis results for the inhalation pathway.

This file: U:\Chevron Renewal\ENVIRON Files\Air Quality\Risk\Shipping\HARP Analysis\Source-Specific\Cancer_70Res_MNTUG.xls

Created by HARP Version 1.4f Build 23.11.01

Uses ISC Version 99155

Uses BPIP (Dated: 04112)

Creation date: 2/20/2014 5:11:27 PM

EXCEPTION REPORT

(there have been no changes or exceptions)

INPUT FILES:

Source-Receptor file: U:\Chevron Renewal\ENVIRON Files\Air Quality\Risk\Shipping\HARP Analysis\Source-Specific\MNTUG.SRC

Averaging period adjustment factors file: not applicable

Emission rates file: MNTUG.EMS

Site parameters file: none

Coordinate system: UTM NAD83

Screening mode is OFF

Exposure duration: 70 year (adult resident)

Analysis method: Derived (Adjusted) Method

Health effect: Cancer Risk

Receptor(s): 7013

Sources(s): All

Chemicals(s): All

This file: U:\Chevron Renewal\ENVIRON Files\Air Quality\Risk\Shipping\HARP Analysis\Chronic-HI_MNTUG.xls

Created by HARP Version 1.4f Build 23.11.01

Uses ISC Version 99155

Uses BPIP (Dated: 04112)

Creation date: 2/24/2014 3:19:03 AM

EXCEPTION REPORT

(there have been no changes or exceptions)

INPUT FILES:

Source-Receptor file: U:\Chevron Renewal\ENVIRON Files\Air Quality\Risk\Shipping\HARP Analysis\Source-Specific\MNTUG\MNTUG.SRC

Averaging period adjustment factors file: not applicable

Emission rates file: MNTUG-HI.EMS

Site parameters file: U:\Chevron Renewal\ENVIRON Files\Air Quality\Risk\Shipping\HARP Analysis\project.sit

Coordinate system: UTM NAD83

Screening mode is OFF

Exposure duration: resident

Analysis method: Derived (OEHHA) Method

Health effect: Chronic HI

Receptor(s): 7013

Sources(s): All

Chemicals(s): All

APPENDIX 4.3 - MET

MET: Evaluation of the Potential for Change in
Crude Constituents with the Project

APPENDIX 4.3-MET

EVALUATION OF THE POTENTIAL FOR CHANGE IN CRUDE CONSTITUENTS WITH THE PROJECT

1.1 INTRODUCTION

Chevron's Modernization Project objective of increasing its flexibility to refine higher sulfur crude and gas oils will result in the acceptance of higher sulfur crude oils and gas oils (i.e., feedstocks to the Refinery) and has the potential to result in the processing of crude oils in a heavier gravity range than was processed during the baseline. The Modernization Project's increase in sulfur removal capacity and the Refinery's ability to process different gravity feedstocks were evaluated as part of both the Air Quality (see *Section 4.3.6.2.1.4.2.1.3*) and Public Safety analyses (see *Appendix 4.13- REL*) of this EIR.

Crude oils and gas oils also contain nitrogen, metals, "reactive sulfur species" (mercaptans), acid, and chlorides that can contribute to corrosion or other equipment damage mechanisms in refinery operations. Accordingly, any potential increases in nitrogen, metals, reactive sulfur species (mercaptans), acid, and chlorides with increasing sulfur content as well as with heavier gravity for the crude oil that may be accepted as a result of the Modernization Project were evaluated below and the conclusions were used as a component of the Public Safety analysis (see *Appendix 4.13-REL*). Increases in these constituents in crude and gas oils could lead to increases in risk from corrosion damage mechanisms associated with these components, as described in more detail in *Appendix 4.13-REL*.

In addition, any change in nitrogen or metals in the feedstocks to the Refinery may also affect air emissions from the Refinery. Increased metals content could lead to increased metals in air emissions, which are usually emitted during the fluid catalytic cracking and thermal processing (EPA, 2011), and increased nitrogen in the feedstock could result in additional emissions of oxides of nitrogen. The data and conclusions on nitrogen and the metals were used as a component of the Air Quality analysis (see *Section 4.3.6.2.1.4.2.1.3*).

1.2 METHODS

Because crude oil occurs naturally in various locations throughout the globe, and because crude quality varies both among different global production areas and even within the same crude extraction fields, a literature search was completed to evaluate whether there is any statistical relationship between the crude oil

sulfur content and API gravity, and whether nitrogen, metals, “reactive sulfur species” (mercaptans), acid, and chlorides content would likely change (e.g., increase), either with increased crude oil sulfur content or with heavier gravity crudes (BP, 2013; Capline, 2013; Eni, 2012; Environment Canada, 2008; Exxon, 2013; Satoil, 2013; Total, 2003).¹ The crude oil data found from various agencies and institutions were statistically evaluated to investigate the potential relationship between the crude oil total sulfur concentration and concentrations of nitrogen, metals, reactive sulfur species (mercaptans), acid, and chlorides. Relationships between gravity (API) and these components were also investigated using a statistical approach.

To perform this statistical analysis, the constituent concentration data was plotted against both sulfur content (in sulfur weight percent (%-wt)) and gravity (in American Petroleum Institute (API)). A statistical relationship was evaluated in this analysis using the Pearson Product-Moment Correlation approach. To be able to use this approach, the data need to generally meet the following conditions:

- The variables must be either interval or ratio measurements.^{2,3} All the plotted data are ratio measurements.
- The variables must be approximately normally distributed, which appears to be generally true for the crude oil data.
- There is a linear relationship between the two variables. The plotted data are generally linear.
- Outliers are kept to a minimum. In this analysis, sub-datasets are studied in order to test the hypothesis of whether outliers might be masking a correlation or whether correlations exist within narrower bands within the entire data set. All these results were accounted for the statistical relationship determinations.
- There is homoscedasticity of the data, which is generally true for the crude oil data.

¹ Unlike crude oils, little public data exists on gas oil constituents. However, as gas oil is derived from crude oils, it is assumed that the results for sulfur vs. nitrogen, metal and other content in crude oil, is likely true for gas oils. The variation of API and nitrogen, metal, and other content in crude oil is likely irrelevant for gas oil, as gas oil is a specific gravity cut of the crude oil.

² A interval variable is a measurement where the difference between two values is meaningful. For example, the difference between a temperature of 100 degrees and 90 degrees is the same difference as between 90 degrees and 80 degrees.

³ A ratio variable has all the properties of an interval variable and also has a clear definition of 0.0. When the variable equals 0.0, there is none of that variable.

A coefficient of determination was generated for each plot shown below. The coefficient of determination, denoted as R^2 , ranges from 0 (0%) to 1 (100%), denotes the strength of the linear association between two variables or how well the data points fit in a predictive linear relationship. For example, an R^2 value of 0.4 means that 40% of the total variation of a constituent concentration can be explained by the linear relationship between the primary variable (e.g., sulfur content or gravity) and the constituent concentration. The other 60% of the total nitrogen variation remain unexplained by this relationship, which implies the linear relationship has a high level of uncertainty, and this relationship cannot be used to make predictions of reasonably likely conditions.

As discussed above, R^2 is coefficient of determination which is a measure of linear dependence between two variables.⁴ Though there is no hard rule for describing correlation strength, ENVIRON considered the following general guidelines in this analysis (Taylor, 1990; Gerstman, 2014; University of Strathclyde, 2014)

- $R^2 \leq 0.1$ to indicate no correlations,
- $0.1 < R^2 < 0.5$ to indicate weak correlations, and
- $R^2 \geq 0.5$ to indicate moderate to strong correlations.

In this analysis, the statistical relationship between two parameters was determined as no correlation, weak correlation, or moderate to strong correlation based on the R^2 value. A moderate to strong correlation indicates a likely relationship exists as more than 50% of the variation can be explained by the linear relationship and predicted trends made using the linear relationship are more likely than not to occur. Thus, moderate to strong correlations are certain enough to provide predictions of reasonable likely changes with the Modernization Project. As weak correlation has greater than 50% unexplained variation, the data confirm some relationship, but the uncertainty is high. If 10% or less of the correlation is explained by the relationship, no predictions can be made based on the parameter tested.

1.2.1 Sulfur Content vs. Gravity

An analysis was conducted to determine whether the variation of sulfur content with gravity of crude oils can be explained by a linear relationship. Based on a

⁴ The coefficient of determination is the square of the correlation coefficient r (ranged from -1 to 0 to +1). A r value of 0 indicates that no linear relationship between the two variables, and a r of -1 or +1 indicates a perfect linear relationship. The positive and negative signs of r explain whether the two variables change in the same or opposite directions, respectively. (<http://www.stat.yale.edu/Courses/1997-98/101/correl.htm>)

visual inspection of available data, there appears to be no linear relationship between the sulfur content and the gravity. Therefore, the coefficient of determination was not evaluated. However, as shown in Figure A4.3-MET-1a, there are more heavier (i.e., lower gravity) high sulfur crudes and fewer lighter (i.e., higher gravity) high sulfur crudes. In fact, as the crude oil gets lighter, the maximum sulfur in the crude oil declines until an API gravity of about 45°, where the crude oils appear to be uniformly sweet with sulfur contents well below 0.5%.

1.2.2 Nitrogen

1.2.2.1 Conclusions

Based on the evaluation of available data on nitrogen content of crude oils, the following was determined:

- A weak statistical relationship was found between nitrogen content and sulfur content of crude oils. Thus, slight increases in nitrogen content of crude oils could be possible with increasing sulfur content crude oils expected with the Modernization Project given the weak correlation.
- A moderate to strong statistical relationship was found between API gravity in the intermediate-lighter gravity range (between 28 and 40 API) and nitrogen content. As the baseline average API was 33.7, the potential for processing heavier API crude oils than were processed during the baseline period as a result of the Modernization Project could result in reasonably likely increases in nitrogen content.

This EIR accordingly concludes that it is likely that the crude oils processed by the Refinery if the Modernization Project is implemented have the potential to contain additional nitrogen.

1.2.2.2 Supporting Data

The publicly available crude oil sulfur weight percentage data and the nitrogen content data in parts per million (ppm) were plotted in Figure A4.3-MET-2a. As shown in Figure A4.3-MET-2a, the R^2 is approximately 0.39. To further explore whether linear correlations exists above and below 1 %wt sulfur, two subsets of the data when sulfur weight percentage is below and above 1% were analyzed in Figures A4.3-MET-2b and A4.3-MET-2c. The R^2 is 0.42 and 0.33 for below and above 1 %wt sulfur, respectively. Based on the data analysis described above, a weak statistical relationship was found between nitrogen content and sulfur content of crude oils.

Satoil; Environment Canada

Figure A4.3-MET-2c
Chevron Refinery Modernization Project EIR
Nitrogen Concentration vs. Sulfur Weight % for Sulfur Weight % > 1%

The dependence of nitrogen on gravity (in API) was also explored. An R^2 value for the crude oil API gravity and nitrogen content (in ppm) is 0.41 as shown in Figure A4.3-MET-2d. To further explore potential correlations in the intermediate range of crudes, an analysis of data when API gravity is between 28 and 40 (intermediate range) was conducted and results in an R^2 value of 0.59 (Figure A4.3-MET-2e). When API gravity is less than 28, the R^2 is 0.26 (Figure A4.3-MET-2f). Based on the data analysis described above, a moderate to strong statistical relationship was found between API gravity in the intermediate-light gravity range (between 28 and 40 API) and nitrogen content. Outside of this range, only a weak correlation was seen.

1.2.3 Metals

1.2.3.1 Conclusions

The crude oil data found from various agencies and institutions were evaluated to investigate the potential relationship between the crude oil total sulfur concentration and gravity to the concentration of barium, iron, magnesium, nickel, titanium, vanadium, and zinc. Little data on mercury, lead, copper, cadmium, and arsenic was available to construct meaningful analysis and therefore the statistical relationship between these metals and sulfur or gravity was not evaluated. Based on the evaluation of available data on metal content of crude oils, the following was determined:

- No statistical relationship was found for the dependence of barium, calcium, magnesium, titanium, and zinc on sulfur (i.e., concentrations of metals did not vary with sulfur concentrations).
- A weak statistical relationship was found for the dependence of iron, nickel and vanadium on sulfur concentration. Thus, it is possible that slight increases in iron, nickel and vanadium content of crude oils could occur with higher sulfur content crude oils expected with the Modernization Project given the weak correlation.
- No statistical relationship was found for the dependence of barium, titanium, and zinc on gravity (API).
- A weak statistical relationship was found for the dependence of calcium, iron, magnesium, nickel, and vanadium on gravity (API). Thus, it is possible that slight increases in calcium, iron, magnesium, nickel and vanadium could occur with lower API crude oils expected with the Modernization Project given the weak correlation.

Source: BP PLC; Total Oil Trading SA; Exxon Mobile Corporation;
Satoil; Environment Canada

Figure A4.3-MET-2e
Chevron Refinery Modernization Project EIR
Nitrogen Concentration vs. API Gravity for API Gravity between 28 and 40

This EIR accordingly concludes that it is possible that the metal content of crude oils processed by the Refinery could increase slightly if the Modernization Project is implemented.

1.2.3.2 Supporting Data

The publicly available crude oil metal concentration data and sulfur weight percent were plotted in Figures A4.3-MET-3a to -3h. As shown in these charts, the R^2 is less than 0.1 for calcium (0.02), magnesium (0.002), titanium (0.0005), and zinc (0.004), and therefore no statistical relationship was found between these metal concentration and sulfur content of crude oils. The R^2 is between 0.1 and 0.5 for barium (0.1), iron (0.18), nickel (0.35), and vanadium (0.31), and a weak statistical relationship was found between the content of these metals and sulfur content of crude oils.

The dependence of metals on gravity (in API) was also explored. As shown in Figure A4.3-MET-3j to -3p, the R^2 is less than 0.1 for barium (0.08), titanium (0.0005), and zinc (0.05), and therefore no statistical relationship was found between these metal concentration and gravity. The R^2 is between 0.1 and 0.5 for calcium (0.2), iron (0.1), magnesium (0.3), nickel (0.3), and vanadium (0.2), and a weak statistical relationship was found between the content of these metals and gravity.

1.2.4 Acids

1.2.4.1 Conclusions

Based on the evaluation of available data on acidity of crude oils, the following was determined:

- No statistical relationship was found between acidity and sulfur content. Thus, increases in acidity of crude oils are not reasonably likely to occur with higher sulfur content crude oils expected with the Modernization Project given the lack of a strong correlation.
- A weak statistical relationship was found between API gravity in the intermediate-light gravity range (28 and 40 API) and acidity. Thus, it is possible that slight increases in acidity of crude oils could occur with lower API crude oils expected with the Modernization Project given the weak correlation.

This EIR accordingly concludes that it is possible that slight increases in the acidity of crude oils processed by the Refinery could occur if the Modernization Project is implemented.

1.2.4.2 Supporting Data

The publicly available crude oil sulfur weight percentage data and the acidity data were plotted in Figure A4.3-MET-4a. As shown in Figure A4.3-MET-4a, the R^2 is approximately 0.0003.

The dependence of acidity on gravity (in API) was also explored. An R^2 value for the crude oil API gravity and acidity is 0.3 as shown in Figure A4.3-MET-4b. To further explore potential correlations in the intermediate range of crudes, an analysis of data when API gravity is between 28 and 40 (intermediate range) was conducted and results in an R^2 value of 0.3 (Figure A4.3-MET-4c). Based on the data analysis described above, a weak statistical relationship was found between API gravity in the intermediate-lighter gravity range (between 28 and 40 API) and nitrogen content.

1.2.5 Mercaptans

1.2.5.1 Conclusions

Based on the evaluation of available data on mercaptan sulfur content of crude oils, the following was determined:

- No statistical relationship was found between mercaptan sulfur content and sulfur content. Thus, increases in mercaptan sulfur content of crude oils are not reasonably likely to occur with higher sulfur content crude oils expected with the Modernization Project given the lack of a strong correlation.
- No statistical relationship was found between mercaptan sulfur content and gravity. Thus, increases in mercaptan sulfur content of crude oils are not reasonably likely to occur with lower API crude oils expected with the Modernization Project given the lack of a strong correlation.

This EIR accordingly concludes that it is not likely that mercaptan sulfur content of crude oils processed by the Refinery would increase if the Modernization Project is implemented.

1.2.5.2 Supporting Data

The publicly available crude oil sulfur weight percentage data and the mercaptan sulfur content data in parts per million (ppm) were plotted in Figure A4.3-MET-4d. As shown in Figure A4.3-MET-4d, the R^2 is nearly zero. To further explore whether the outlier might be masking the correlation, a subset of the data when mercaptan sulfur concentration is below 500ppm were analyzed in Figures A4.3-MET-4e. The resulting R^2 is 0.03. Based on the data analysis described above, no statistical relationship was found between nitrogen content and sulfur content of crude oils.

Figure A4.3-MET-4e
Chevron Refinery Modernization Project EIR
Mercaptan Sulfur Concentration vs. Sulfur Weight % for Mercaptan Sulfur < 500ppm

The dependence of mercaptan sulfur on gravity (in API) was also explored. An R^2 value for the crude oil API gravity and nitrogen content (in ppm) is 0.0007 as shown in Figure A4.3-MET-4f. To further explore whether the outlier might be masking the correlation, a subset of the data when mercaptan sulfur concentration is below 250 ppm was analyzed in Figure A4.3-MET-4g. The resulting R^2 is 0.03. Based on the data analysis described above, no statistical relationship was found between API gravity and mercaptan sulfur content of crude oils over a wide gravity range (approximately 20 to 73 API).

1.2.6 Salt Content (Includes Chlorides)

1.2.6.1 Conclusions

Based on the evaluation of available data on salt content of crude oils, the following was determined:

- No statistical relationship was found between salt content and sulfur content. Thus, increases in salt content of crude oils are not reasonably likely to occur with higher sulfur content crude oils expected with the Modernization Project given the lack of a strong correlation.
- No statistical relationship was found between salt content and gravity. Thus, increases in salt content of crude oils are not reasonably likely to occur with lower API gravity crude oils expected with the Modernization Project given the lack of a strong correlation.

This EIR accordingly concludes that it is not likely that salt content of crude oils processed by the Refinery would increase if the Modernization Project is implemented.

1.2.6.2 Supporting Data

The publicly available crude oil sulfur weight percentage data and the salt content data were plotted in Figure A4.3-MET-4h. As shown in Figure A4.3-MET-4h, the R^2 is 0.1, and therefore a weak statistical relationship was found between sulfur content and salt content of crude oils.

The dependence of salt content on gravity (in API) was also explored. An R^2 value for the crude oil API gravity and salt content is 0.1 as shown in Figure A4.3-MET-4i, and therefore a weak statistical relationship was found between API gravity and salt content of crude oils over a wide gravity range (approximately 20 to 73 API).

APPENDIX 4.3 - MIT

Mitigation Measures

APPENDIX 4.3-MIT MITIGATION MEASURES

The Draft EIR identified mitigation measures that would reduce emissions to less than significant levels (for CEQA purposes) and to "no net increase" (NNI) for purposes of achieving an applicant project objective. Several commenters raised questions about the quantitative reductions associated with each mitigation measure. This new Appendix 4.3 "shows the math" by explaining the quantitative emission reduction calculations that were used in the Draft EIR to reach the conclusion that, as mitigated, the Project would result in NNI in criteria air pollutants (CAPs) and risks from toxic air contaminants (TACs) for both the 93% and 100% Utilization Scenarios.

Other commenters also asked for more specificity about how mitigation measures were prioritized, and requested that physical emission reductions from Facility operations be prioritized ahead of the use of emission reduction credits (ERCs) for CAPs. All mitigation required to reduce risks from TACs were required to be achieved with offsetting physical emission reductions. The mitigation measures for CAPs listed physical emission reduction mitigation measures before ERCs, but did not clearly specify that physical reduction measures must be implemented ahead of ERCs. This prioritization of physical mitigation measures ahead of ERCs has been clarified with revised mitigation measures as explained in the Final EIR (see *Response B12-20*). Please note that the existing regulatory system does not allow the use of ERCs for TAC reductions; therefore, no ERCs were used for TAC reductions. While Mitigation Measure 4.3-5 allows for the use of ERCs for certain CAPs (respirable particulate matter, less than 10 microns in diameter [PM_{10}], fine particulate matter [$PM_{2.5}$], and reactive organic gas [ROG]), the mitigation for TAC risks under Mitigation Measure 4.3-6a are sufficient to achieve compliance with both the Bay Area Air Quality Management District's (BAAQMD) CEQA significance thresholds and NNI in TAC health impacts from Baseline conditions. This appendix also shows this prioritization of physical emission reduction mitigation measures, and identifies with specificity the Mitigation Measures that are required to achieve NNI for the 93% utilization level and the 100% utilization level—for CAPs and for health impacts from TACs.

Mitigation measure calculations are presented below for each CAP and for risk mitigations from diesel particulate matter (DPM) reductions from ships (which is the driver of health risks from TACs).

1.1 SULFUR OXIDES MITIGATION

This section describes the background for the sulfur oxides (SO_x) mitigation proposed as a part of the Chevron Refinery Modernization Project (Modernization Project, or Project) as well as the methods used to estimate the efficacy of that mitigation.

1.1.1 Background

As discussed in Mitigation Measure 4.3-9 of the Chevron Refinery Modernization Project Draft Environmental Impact Report (Draft EIR), *Section 4.3, Air Quality*, no additional SO_x mitigation is required under any of the 93% Utilization Scenarios. Please see *Response B12-20* for modifications to Mitigation Measure 4.3-9, as described above. Table 4.3-20 of the Draft EIR shows that very slight increases in SO_x (1–3 tons/year, depending on the scenario) would occur at the 100% utilization levels; thus, mitigation is required for the 100% Utilization Scenarios. The quantity of SO_x mitigation reductions required will depend on actual SO_x emissions, as reported annually in the BAAQMD Emissions Inventory. Any 1-year exceedance of the Baseline will trigger the need for additional SO_x mitigation, which will result in annual SO_x reductions below Baseline even if such exceedances do not recur in future years. Chevron shall achieve the NNI Project Objective for SO_x by implementing one or more of the following feasible mitigation measures:

Chevron shall increase the use of SO_x -reducing catalyst material that has been demonstrated to substantially reduce SO_x emissions in refinery flue gases. This is a feasible means of reducing SO_x in flue gas in the very low quantities needed to achieve the NNI Project Objective for SO_x , even under the highest SO_x emission scenario identified in Table 4.3-22 of the Draft EIR.

After implementing the above measure, if additional mitigation is required, Chevron will permanently retire ERCs to offset any SO_x over Baseline, to achieve the NNI Project Objective for SO_x . Permanent retirement of ERCs assures that these "banked" emissions cannot occur within Richmond or elsewhere in the Bay Area. If such reductions do not achieve the NNI objective, Chevron must curtail emissions to a level that achieves this objective.

1.1.2 Methodology and Results

This section explains the methodology and supporting information used to estimate SO_x emissions reductions associated with using the SO_x -reducing catalyst materials in the fluid catalytic cracker unit. The Facility used SO_x -reducing catalyst in order to comply with consent decree requirements for fluid

catalytic cracker SO_x emissions. The requirements that came in to effect in October 2006 were included under Condition #11066 (4.b) of the Title V Permit:

“4.b. The owner/operator of S-4285 shall not exceed 25 ppmvd SO₂ @ 0% O₂ on a 365 day rolling average and 50 ppmvd SO₂ @ 0% O₂ on a 7 day rolling average (effective 10/31/06). SO₂ emissions during startup, shutdown, or malfunction shall not be used in determining compliance with this 7 day rolling average SO₂ emission limit, provided that good air pollution control practices to minimize SO₂ emissions are implemented during these periods. (basis: consent decree case # 03-04650, date: 6/27/05)”

The 2005 monthly continuous emission monitoring system reports from January through May show representative fluid catalytic cracker operations prior to the consent decree limit (Chevron Data Transmittal #76 (Rev #1), Attachment #2, 2014), which demonstrates the high sulfur dioxide reduction performance of the SO_x-reducing catalyst when compared to the 2008-2010 continuous emission monitoring system reports (Chevron Data Transmittal #66, 2014). As shown in Tables A4.3-MIT-1 and A4.3-MIT-2 below, the average 24-hour and maximum 1-hour monitored SO_x concentration in fluid catalytic cracker exhaust emissions are much higher in 2005 (pre-requirement) and significantly lower in 2009 (post-requirement).

TABLE A4.3-MIT-1 COMPARISON OF MONITORED 24-HOUR AVERAGE SO_x CONCENTRATION BETWEEN 2005 AND 2009

Summary	24-Hour Average Monitored SO_x Concentration (ppm)		
	2005	2009	Difference
January	156.0	16.0	140.0
February	147.9	15.6	132.3
April	134.6	14.8	119.8
May	170.6	11.8	158.8
Average	152.3	14.6	137.7

Note: ppm = parts per million

The continuous emission monitoring system reports also present the estimated SO_x emissions based on the monitored concentration. Table A4.3-MIT-3 below presents the 2005 and 2009 average monthly emissions, the monthly SO_x reduction, and the projected annual SO_x reduction based on the monthly reduction for January, February, April, and May.

TABLE A4.3-MIT-2 COMPARISON OF MONITORED 1-HOUR MAXIMUM SO_x CONCENTRATION BETWEEN 2005 AND 2009

Summary	1-Hour Maximum Monitored SO _x Concentration (ppm)		
	2005	2009	Difference
January	186.3	19.2	167.1
February	177.2	18.5	158.8
April	180.1	18.5	161.5
May	200.7	15.2	185.6
Average	186.1	17.8	168.2

SO_x-reducing catalyst is a known control technology for fluid catalytic cracker sulfur dioxide listed in the BAAQMD Best Available Control Technology Manual.¹ As shown in Table A4.3-MIT-3, the use of SO_x-reducing catalyst for complying with consent decree requirements reduced the SO_x emissions by approximately 117 tons when comparing SO_x emissions from January 2009 to those in January 2005. The monthly SO_x emissions from February to May for 2005 and 2009 were also compared, and the reductions by month were used to calculate the average monthly SO_x emissions reduction (i.e., approximately 138 tons/month). The

¹ <http://hank.baaqmd.gov/pmt/bactworkbook/default.htm>.

average annual SO_x emissions reduction of 1,654 tons/year resulting from the use of SO_x-reducing catalyst was estimated by multiplying the average monthly SO_x emissions reduction by 12. The additional 1–3 tons/year of SO_x emissions reduction needed to achieve NNI for the 100% Utilization Scenarios is less than 0.2% of the estimated annual SO_x emissions reduction and can be achieved through the use of additional SO_x reducing catalyst in the fluid catalytic cracker unit.

In addition, Table A4.3-MIT-3 also presents the annual SO_x reduction projected based on the individual monthly SO_x reduction. The reduction ranges from 1,325 to 2,239 tons/year. Compared to the average annual SO_x reduction, the lowest annual reduction is about 329 tons lower, and the highest is 585 tons higher. The additional 1–3 tons/year of SO_x emissions reduction needed to achieve NNI is less than 0.3% of difference between the high and low. Therefore, this is a feasible SO_x mitigation measure.

1.2 PARTICULATE MATTER MITIGATION

This section describes the background for the PM₁₀ mitigation proposed as a part of the Modernization Project, and also the methods used to estimate the efficacy of that mitigation.

1.2.1 Background

As discussed in Mitigation Measure 4.3-7 of the Draft EIR *Section 4.3, Air Quality*, as revised in *Response B12-20*, no additional mitigation measures for PM₁₀ are required under any of the 93% Utilization Scenarios. PM₁₀ mitigation is required for the 100% Utilization Scenarios. The quantity of PM₁₀ mitigation reductions required will depend on actual PM₁₀ emissions, as reported annually in the BAAQMD Emissions Inventory. Any 1-year exceedance of the Baseline will trigger the need for additional PM₁₀ mitigation, which will result in annual PM₁₀ reductions below Baseline even if such exceedances do not recur in future years. As described in Mitigation Measure 4.3-7 of the Draft EIR, as revised in *Response B12-20*, Chevron shall reduce PM₁₀ emissions to below BAAQMD Significance Thresholds, and achieve the NNI Project Objective, by implementing the following feasible mitigation measure:

Chevron shall increase the size of the fluid catalytic cracker electrostatic precipitator (ESP) by approximately 50% to eliminate an existing ammonia injection process in the flue gas in the fluid catalytic cracker unit. The ammonia injection process currently occurs before the flue gas is passed through the ESP, and helps remove particulates from the flue gas. Ammonia is also produced by the refinery process, and the reuse of ammonia reduces the quantity of ammonia stored and transported as a product. The ESP

removes particulates from the flue gas with an electrical charge that causes the particulates to attach to a plate that is then periodically cleaned. Eliminating the ammonia injection treatment of the flue gas will significantly reduce PM_{10} emissions, with the potential for up to 50 tons/year of PM_{10} reductions (or approximately double the quantity of PM_{10} reductions required to achieve the NNI Project Objective for the scenarios depicted in Table 4.3-22 of the Draft EIR).

After implementing the above measure, if additional mitigation is required, Chevron will permanently retire ERCs to offset any PM_{10} over Baseline, to achieve the NNI Project Objective for PM_{10} . Permanent retirement of ERCs ensures that these "banked" emissions cannot occur within Richmond or elsewhere in the Bay Area. If such reductions do not achieve the NNI objective, Chevron must curtail emissions to a level that achieves this objective.

This section describes how the injection of ammonia using the current equipment configuration at the Facility results in a significant portion of particulate matter (PM) emissions that are captured as condensable PM. This section also discusses the methodology used to estimate PM_{10} emissions reductions from eliminating the ammonia injection by resizing the fluid catalytic cracker ESP, as discussed in the first mitigation measure above.

1.2.2 Methodology and Results

Emissions from fluid catalytic cracker units may result from the following mechanism: (1) catalyst fines that escape the catalyst recovery and air pollution control equipment; (2) sulfur trioxide and sulfuric acid, which originate from sulfur in fuels, a small fraction (typically 2–10%) of which may be converted to sulfur trioxide and/or sulfuric acid aerosols; (3) particulate and certain semi-volatile organic compounds that may be both generated and consumed during the combustion process and from mineral matter; and (4) ash and other incombustible residues in fuels and feed materials.

Many fluid catalytic cracker units are equipped with ESPs for catalyst removal and PM emissions control. Ammonia is often injected upstream of an ESP to enhance PM collection efficiency, reacting with sulfuric acid to form ammonium sulfate and/or ammonium bisulfate aerosols—"sticky" (i.e., charged) particles that combine with dust or particulates making the particulates larger and easier to remove.

This ammonia application generally results in some level of excess ammonia present in the vent gas at the stack. Gaseous ammonia can contribute to primary PM emissions via reaction with sulfur trioxide and/or sulfuric acid, if present in the stack gas, to form sulfate aerosols. Similar reactions may occur with

ammonia and hydrogen chloride gas, if present, to form ammonium chloride aerosols. Reducing ammonia injection requires upgrading of the ESP to ensure the same level of PM reduction.

Increasing the collection area by adding fields to an existing ESP can significantly improve PM collection efficiency. Under normal conditions in a well-designed ESP, most of the particles will be collected in the first (upstream) fields and ESP emissions are dominated by re-entrainment of fine dust from the last (downstream) field of the ESP during rapping. Adding new fields downstream of an existing ESP can be very effective, as can simply adding collection area similar in design to the existing ESP. A properly designed field addition to the existing ESP should achieve similar or better PM reductions compared with ammonia injection.

The presence of ammonia downstream of the ESP results in a significant portion of PM that is measured as condensable PM emissions (Chevron Data Transmittal #74 (Rev #1), 2014). Increasing the size of the fluid catalytic cracker ESP by approximately 50% counteracts the effect of eliminating ammonia injection and not conditioning the particulates. The PM emissions reduction from this mitigation measure was quantified in two scenarios using the 2011 ammonia injection quantity of 223,187 pounds (lbs) from the 2011 report year Toxic Release Inventory report² and ammonia slip factor of 50% from the 2010 BAAQMD source test. The detailed calculations and BAAQMD source test data are presented below.

In the first scenario, the ammonia emissions of 111,850 lbs/year due to ammonia slip were assumed to become condensable PM₁₀, which results in PM₁₀ emissions of 55.9 tons/year, as presented in Table A3.4-MIT-4 below. This approach is conservative because ammonia is lighter than the most common ammonia-based condensable PM₁₀ emissions (ammonium sulfate), and thus underestimates the PM₁₀ reduction. As an additional layer of conservatism, the PM₁₀ reductions of 55.9 tons/year due to elimination of the ammonia injection process were rounded down to 50 tons/year (Chevron Data Transmittal #74 (Rev #1), 2014). To achieve NNI for all Modernization Project scenarios, a PM₁₀ emissions reduction of 31 tons/year is required, which is less than the PM₁₀ reduction due to this measure.

In the second scenario, the South Coast Air District Management 2013 Final Environmental Assessment (EA) (SCAQMD, 2003) was used to estimate PM

² 2011 was the first year reporting the full-year ammonia injection quantity after the BAAQMD's ammonia slip source test. 2012-2013 data were not used because of the crude unit fire shutdown.

reductions. This assessment indicates that condensable emissions from fluid catalytic cracker unit consist primarily of ammonium sulfate, which forms both in the sampling apparatus and in the atmosphere as the results of both ammonia (due to ammonia slip) and sulfur trioxide and/or sulfuric acid gases being presented in the stack. The 2003 Final EA also mentioned that it is reasonable to expect that all of the ammonia will react to form ammonium sulfate when ammonia is the limiting component. Consistent with the Final EA, in this calculation, all ammonia was assumed to convert into ammonium sulfate (217 tons/year) and is measured as condensable PM₁₀, as presented in the Table A4.3-MIT-4, below. Therefore, by eliminating ammonia injection, a reduction of 217 tons/year of condensable PM₁₀ emissions would be obtained under this scenario; which is approximately 7 times the quantity of PM₁₀ reductions required to achieve the NNI Project Objective for the 100% Utilization Scenarios depicted in Table 4.3-22 of the Draft EIR.

TABLE A4.3-MIT-4 QUANTIFICATION OF CONDENSABLE PM REDUCTION

Scenario	Ammonia Injection ^a (lbs)	Ammonia Slip Factor ^b	Ammonia Slip (lbs)	Condensable PM (lbs)		Condensable PM (ton)	
				As Ammonia ^c	As Ammonium Sulfate ^{d,e,f,g}	As Ammonia ^h	As Ammonium Sulfate ^h
Unmitigated	223,187	50%	111,594	111,594	433,920	55.9	217
Mitigated ⁱ	0		0	0	0	0	0
Condensable PM ₁₀ Reduction				111,594	433,920	55.9	217

^a 2011 ammonia injection quantity from the 2011 report year Toxic Release Inventory report.

^b From 2010 BAAQMD source test.

^c Assuming all ammonia slip emissions become condensable PM₁₀ emissions

^d Calculated by: $\text{Ammonia Injection lb} \times \text{Ammonia Slip Factor \%}$

^e Assumed all ammonia (molecular weight = 17 lbs/lb-mole) slip was converted to ammonium sulfate (molecular weight = 132 lbs/lb-mole) and is measured as condensable PM₁₀.

^f The reaction stoichiometry dictates that 2 moles of ammonia form 1 mole of ammonium sulfate.

^g Calculated by: $\text{Ammonia Slip} \times 132 \frac{\text{lb}}{\text{lb-mole}} \div 17 \frac{\text{lb}}{\text{lb-mole}} \div 2 \frac{\text{mole NH}_4}{\text{Mole (NH}_4)_2\text{SO}_4}$

^h Calculated by: $\text{Ammonium Sulfate or Ammonia Emissions} \frac{\text{lbs}}{\text{year}} \div 2000 \frac{\text{lbs}}{\text{ton}}$

1.3 ROG MITIGATION

This section describes the background for the ROG mitigation proposed as a part of the Modernization Project, and also the methods used to estimate the efficacy of that mitigation.

1.3.1 Background

As discussed in Mitigation Measure 4.3-5f in *Section 4.3.6.2.4* on pages 4.3-92 through 94 of the Draft EIR, and modified by *Response B12-20*, additional ROG mitigation is required under all Modernization Project scenarios, in quantities ranging from 12 to 65 tons/year. ROG reductions required under the 93% Project Scenario are 25 tons/year, and those required under the 100% Utilization Scenario are 54 tons/year, as indicated in Table 4.3-22. ROG emissions increase with Facility utilization levels, with only the lowest utilization level—for Very Heavy Crude Oil (included in Table 4.3-20 of the Draft EIR)—having a net decrease in ROG relative to the Baseline.

Reducing ROG requires lowering volatile organic compound (VOCs) emissions from the Facility. A very high percentage of these VOCs are emitted (or assumed to be emitted for BAAQMD rulemaking and inventory purposes) from miscellaneous small sources, such as the valves and flanges on pipes at the Facility. The most significant opportunity to reduce VOCs at the Facility is to install fixed domes over the large tanks used to store feedstocks and products. The tanks already have floating roofs to reduce VOCs, but adding a fixed dome further reduces VOC emissions by eliminating the effect of wind. Chevron has proposed as Project Design Feature to install a dome on Tank 3225 prior to commencement of Project operations, which is estimated to reduce ROG emissions by 2.1 tons/year. As mitigation, the EIR further requires Chevron to install two additional domes on Tanks 3189 and 3202 within 3 years following the commencement of Project operations, which is estimated to reduce ROG emissions by an additional 3.9 tons/year. Please see Mitigation Measure 4.3-5f, as revised by *Response B12-20*. Chevron has also identified an additional 27 tanks that could be domed, representing cumulative VOC reduction opportunities of approximately 63.7 tons/year. Chevron recently provided new information on tank dome reductions (Chevron Data Transmittal #75 (Rev #3) 2014); however, this new information has not been verified by the BAAQMD. Prior to granting mitigation credit for any tank doming project, a permit will have to be filed with the BAAQMD and the actual reductions will have to be verified by the BAAQMD during the permitting process.

As described on page 4.3-93 of the Draft EIR, the quantity of ROG mitigation reductions required will depend on actual ROG emissions, as reported annually in the BAAQMD Emissions Inventory. Any 1-year exceedance of the Baseline will

trigger the need for additional ROG mitigation, which will result in annual ROG reductions below Baseline even if such exceedances do not recur in future years. As described in the Draft EIR, Chevron shall reduce ROG emissions to below BAAQMD Significance Thresholds, and to ensure no net increase in Project ROG emissions above Baseline ROG emissions, by implementing Mitigation Measure 4.3-5f as revised in *Response B12-20*. As revised, this mitigation measure prioritizes physical mitigation (e.g., doming tanks).

After implementing the above measure, if additional mitigation is required, Chevron will permanently retire ERCs to offset any ROG over Baseline, to achieve the NNI Project Objective for ROG Permanent retirement of ERCs ensures that these "banked" emissions cannot occur within Richmond or elsewhere in the Bay Area. If such reductions do not achieve the NNI objective, Chevron must curtail emissions to a level that achieves this objective.

The evaluation that was conducted to confirm the ROG reduction of these mitigation measures follows.

1.3.2 Methodology and Results

This section explains the methodology used to estimate ROG emissions reductions associated with installation of tanks domes, as discussed in the first mitigation measure above. The emissions reductions from the tank domes were estimated by modeling the post- Modernization Project throughput for each tank with the United States Environmental Protection Agency (EPA) TANKS v4.09D program. This program was used to determine emissions reductions for all tank domes during the permitting process.

TANKS is a Windows-based computer software program developed by the EPA for estimating VOC and hazardous air pollutant emissions from both fixed roof and floating roof storage tanks. TANKS is based on the emission estimation procedures from Chapter 7 of the EPA's Compilation of Air Pollutant Emission Factors (AP-42) (EPA 2006b).³ TANKS uses chemical, meteorological, roof fitting, and rim seal data to generate emissions estimates for several types of storage tanks—including vertical and horizontal fixed roof tanks, internal and external floating roof tanks, domed external floating roof tanks, and underground tanks.

For each tank, the reduced ROG emissions (i.e., with tank dome) were modeled with TANKS V4.09D using the "domed external floating roof tank" option, and emissions without tank a dome were modeled using the "external floating roof tank" option. The modeled material, roof fitting, and rim seal data for each tank

³ <http://www.epa.gov/ttnchie1/software/tanks/>.

were provided in Chevron Data Transmittal #58 (2013) and Chevron Data Transmittal #75 (Rev #1, 2014). The TANKS default meteorological data at San Francisco International Airport (San Francisco AP, California) were used for the model. The tank ROG emissions reduction or the difference in ROG emissions between the domed and undomed tanks for each tank is summarized in the tables below. The cumulative ROG emissions reductions are also summarized in these tables.

1.4 NITROGEN OXIDES MITIGATION MEASURES

This section describes the background for the nitrogen oxides (NO_x) mitigation proposed as a part of the Modernization Project, and also the methods used to estimate the efficacy of that mitigation.

1.4.1 Background

Mitigation Measure 4.3-5a in *Section 4.3.6.2.4* of the Draft EIR, as revised by *Response B12-20*, describes one Project Design Feature and two mitigation measures that reduce NO_x emissions:

1. **Suezmax Engine Upgrades:** To achieve its commitment of NNI in CAP emissions, Chevron has included an emission-reduction Project Design Feature for shipping in the Project. The Project Design Feature is to upgrade engines on two new Chevron Suezmax ships with low-emission engine technologies that result in fewer emissions than required under applicable emission control laws for ships built in 2014. As described in Draft EIR *Section 4.3.6.2.4*, Chevron is removing three Suezmax vessels from West Coast service; these will be replaced with two newly built Suezmax ships in 2014. Chevron has proposed as a Project Design Feature to upgrade the engines on the new Chevron Suezmax ships with low-emission engine technologies that result in fewer emissions than required under applicable emission control laws for ships built in 2014.
2. **Cleaner Tug Boats:** Chevron shall fund and require installation of cleaner main and auxiliary engines on up to six tug boats serving the Long Wharf as well as non-Chevron facilities. Tugs are used to push barges, escort ships and barges, and assist ships and barges into berths. The Long Wharf is primarily served by six tugs. Under applicable California Air Resources Board (CARB) rules, four of these tugboats are required to be retrofitted with cleaner engines meeting designated Tier 2 emission standards, over a phase-in period ending as late as 2022. The remaining two tugboats are required to be retrofitted with cleaner engines meeting designated Tier 3 emission

TABLE A4.3-MIT-5 SUMMARY OF TANK DOME ROG EMISSIONS REDUCTIONS

Tank No.	Service^a	Reduction by Tank (tons/year)	Cumulative Reduction^b (tons/year)
3189	Gasoline	2.6	2.6
3202	Hydrocracker Feed	1.3	3.9

TABLE A4.3-MIT-5 SUMMARY OF TANK DOME ROG EMISSIONS REDUCTIONS

Tank No.	Service^a	Reduction by Tank (tons/year)	Cumulative Reduction^b (tons/year)
3075	Gasoline	1.1	63.7

^a This table does not restrict changes in tanks service as would otherwise be allowed by BAAQMD regulations and operating permits.

^b There are differences in tank dome reductions based on throughput for each Project utilization scenario. However, the differences are small enough that these values are representative for all Project utilization scenarios.

^c There is an additional 2.1 tons/year reduction from installation of a dome on Tank 3225, which is a Project Design Feature.

Source: Chevron Data Transmittal #75 (Rev #1), 2014; Chevron Data Submittal #75 (Rev #3), 2014.

standards in 2017. Chevron shall fund the installation of new, cleaner Tier 4 main engines and Tier 3 auxiliary engines for the number of tugs required to remain below the BAAQMD NO_x significance threshold. This mitigation measure would result in NO_x emission decreases of up to 107 tons/year, in excess of the 75-tons/year increase over Baseline that would occur under the highest NO_x emissions scenario (100% Utilization, Lightest Crude) included in Table 4.3-22.

3. **Parcel Size Optimization:** Chevron shall increase the average parcel size (the average ship cargo volume that is delivered or picked up from the Long Wharf) to reduce the number of ship calls, and thereby reduce DPM emissions from shipping. This mitigation measure would also result in NO_x emission decreases of up to 59 tons/year, a substantial portion of the 75-tons/year increase over Baseline that would occur under the highest NO_x emissions scenario (100% Utilization, Lightest Crude) included in Table 4.3-22.

After implementing the above measure, if additional mitigation is required, Chevron will permanently retire ERCs to offset any NO_x over Baseline, to achieve the NNI Project Objective for NO_x. Permanent retirement of ERCs ensures that these "banked" emissions cannot occur within Richmond or elsewhere in the Bay Area. If such reductions do not achieve the NNI objective, Chevron must curtail emissions to a level that achieves this objective.

1.4.2 Methodology and Results

This section explains the methodology used to estimate NO_x emissions reductions associated with each of the NO_x mitigation measures.

1.4.2.1 Suezmax Engine Upgrades

Under current regulations, the replacement of the Suezmax ships require installation of main ship and auxiliary ship engines with a level of emission control called Tier 2 under the International Maritime Organization (IMO) requirements (IMO, 2008)⁴ for new engines that have been adopted by the EPA. These Tier 2 emissions are incorporated into the Baseline (resulting in a decrease in NO_x from these ships). As a Project Design Feature, Chevron would install technologies that would lower emissions further than what is required for ships built in 2014 as follows: (1) the main ship diesel engines would be upgraded to meet the IMO Tier 3⁵ standard (versus the required Tier 2), which would reduce NO_x emissions from the main ship engine beyond those required by regulation; and (2) auxiliary engines would be upgraded with turbogenerators to meet requirements more stringent than IMO Tier 3 standards (versus the required Tier 2), which would eliminate DPM emissions (a TAC emission) and reduce NO_x emissions.

The emission reduction features of this Project Design Feature were calculated using the same methodology as was used in the estimation of shipping emissions, as described in Draft EIR *Appendix 4.3-SHP*. The reduction in NO_x emissions from this mitigation measure are 51 tons/year for the Project 93% Scenario and the Max Light 93% Scenario and 55 tons/year for the 100% Project Scenario and the 100% Max Light Scenario.

1.4.2.2 Cleaner Tug Boats

The emissions reductions from the tug boat engine replacements were estimated based on primary data for the 2008-2010 operation of the six tugs that would be replaced using the same emission estimation methodology as described for tug boats (Chevron Data Transmittal #26F, 2014), accounting for emission reductions achieved by the new Tier 4 main and Tier 3 auxiliary engines. Tug boat NO_x emission reductions were calculated only for the transiting mode; emissions during maneuvering or idling were conservatively not accounted for. If this were accounted for, emissions reductions would be even greater. 2008-2010 transiting information for the tug boats was used to estimate the hours of travel by transiting leg. The reduction in NO_x emissions from this mitigation measure are 97, 104, 101, and 107 tons/year for the 93% Project Scenario, 100% Project Scenario, 93% Max Light Scenario, and 100% Max Light Scenario, respectively.

⁴ The Tier 2 MARPOL Annex IV emission standard (applicable to new engines from 2012 to 2015) requirement for a main diesel engine is 14.4 grams NO_x per kilowatt-hour for engines less than 130 revolutions per minute (rpm).

⁵ The Tier 3 MARPOL Annex VI emission standard (applicable to new engines in IMO defined emission control areas from 2016 on) requirement for a main diesel engine is 3.4 grams NO_x per kilowatt-hour for engines less than 130 rpm.

1.4.2.3 Parcel Size Optimization

The emissions reductions from the parcel size optimization mitigation were estimated using the shipping model (Chevron Data Transmittal #26F, 2014). Emission estimates were calculated in the shipping model for the 100% Light Max Scenario by increasing parcel size by reasonable amounts. Parcel size was optimized for Chevron Suezmax, and Product ships. The parcel size as a percentage of capacity before and after the optimization is shown in Table A4.3-MIT-6 below:

TABLE A4.3-MIT-6 SHIP PARCEL SIZE AS A PERCENT OF CAPACITY BEFORE AND AFTER PARCEL SIZE OPTIMIZATION

Operator	Ship Type	Engine Type	Pump Type	Before Optimization		After Optimization	
				Load	Discharge	Load	Discharge
Chevron	Aframax	SSD	Steam	12.0%	0.0%	60.0%	0.0%
	Suezmax	SSD	Steam	0.0%	59.5%	0.0%	80.0%
	Product	SSD	Diesel	30.5%	17.8%	70.0%	60.0%
			Steam	51.7%	14.9%	70.0%	60.0%

Note: SSD – slow speed diesel engine

Source: Chevron Data Transmittal #73 (Rev #3), 2014.

Similarly, parcel size was optimized for Barge 2D and Barge 4D, as shown in Table A4.3-MIT-7.

TABLE A4.3-MIT-7 BARGE PARCEL SIZE AS A PERCENT OF CAPACITY BEFORE AND AFTER PARCEL SIZE OPTIMIZATION

Barge Type	Tug Engine Type	Before Optimization		After Optimization	
		Load	Discharge	Load	Discharge
BARGE1D	HSD	81.0%	0.0%	81.0%	0.0%
	MSD	87.4%	2.4%	87.4%	2.4%
BARGE2D	HSD	82.4%	7.2%	82.4%	7.2%
	MSD	72.4%	17.6%	80.0%	17.6%
BARGE3D	MSD	85.9%	0.9%	85.9%	0.9%
BARGE4D	MSD	50.1%	0.0%	80.0%	0.0%

Note: HSD = high speed diesel engine; MSD = medium speed diesel engine

Source: Chevron Data Transmittal #73 (Rev #3), 2014.

Optimized average parcel sizes were all less than average ship capacity estimates. Because of the increased parcel size for ships and barges, the annual calls will be reduced by 97 calls for ships, and by 10 calls for barges, respectively, for the 100% Light Max Scenario. Table A4.3-MIT-8 shows for the 100% Light Max Scenario, approximate estimates by ship and barge type, calls reduced, emissions available for mitigation per call, and associated NO_x emission reductions. NO_x emission reductions per call shown in Table A4.3-MIT-8 are estimates of emissions available for reduction from parcel size optimization, including all transit and maneuvering mode emissions and non-pumping at-berth emissions; pumping mode and stand-by tug emissions are not affected by parcel size optimization and are excluded from these estimates.

TABLE A4.3-MIT-8 REDUCTIONS IN ANNUAL CALLS AND NO_x EMISSIONS DUE TO PARCEL SIZE OPTIMIZATION

Ship Type	100% Light Max Scenario Annual Calls	Reduced Annual Calls Due to Parcel Size Optimization	NO_x Emissions per Call Available for Mitigation (tons/call)	NO_x Emission Reductions (tons/year)
SuezMax	145	28	0.31	8.5
Products	208	63	0.70	44.5
AfraMax	43	6	0.87	5.2
BARGE2D	207	9	0.08	0.7
BARGE4D	2	1	0.35	0.2
Totals	605	107		59.2

Source: Chevron Data Transmittal #73 (Rev #3), 2014.

The reductions in NO_x emissions from this mitigation measure are 53, 58, 56, and 59 tons/year for the 93% Project Scenario, 100% Project Scenario, 93% Max Light Scenario, and 100% Max Light Scenario, respectively.

1.5 QUANTIFICATION OF TOXIC AIR CONTAMINANT MITIGATION MEASURES AND RESULTING RISKS

This section describes the background for the TACs mitigation proposed as a part of the Modernization Project, and also the methods used to estimate the efficacy of that mitigation. It also presents the revised health risk assessment (HRA) that is based upon the TACs reduction.

Only cancer risk is considered in this section because, as described in *Appendix 4.3-HRA* and *Section 4.3.6.2.5* of the Draft EIR and further described in Master Response 4: Toxic Air Contaminants, only cancer risk exceeds the NNI health impact threshold for all scenarios. Non-cancer chronic and acute and $PM_{2.5}$ concentrations were all below the NNI threshold in residential locations without Project mitigation.

As described in Draft EIR *Section 4.3.6.2.5* (page 102), for operational emissions, inhalation was determined in the HRA to be the critical exposure pathway, and was evaluated in detail. A thorough multipathway TAC impact assessment conducted as part of the Final EIR affirmed the findings of the Draft EIR screening level assessment that non-inhalation pathways do not change or meaningfully affect the significance of the health impacts analysis. Inclusion of the effects of the multipathway assessment would not result in an exceedance of the TAC health impact NNI commitment. Please see Master Response 4: Toxic Air Contaminants.

1.5.1 Background

The incremental, unmitigated TAC emissions and risks resulting from the Project are presented and discussed in *Section 4.3.6.2.5* of the Draft EIR and *Section 1.7* of *Appendix 4.3-HRA*. Mitigation Measure 4.3-6a includes four mitigation measures (inclusive of the Suezmax replacement Project Design Feature) to reduce DPM emissions and health risks. Mitigation Measure 4.3-6a has been modified, as provided in Master Response 4: Toxic Air Contaminants, to add further specificity and to clarify that if health risk from Project TAC emissions remains above Baseline levels on a net basis as determined by the health risk assessment required by Mitigation Measure 4.3-6b, then Chevron shall curtail Facility operations as necessary to ensure that such health risk is reduced to Baseline levels on a net basis.

These mitigation measures are described in further detail below:

1. **Suezmax Engine Upgrades:** To achieve its commitment of NNI in CAP emissions from shipping, Chevron has included an emission-reduction Project Design Feature for shipping in the Project. The Project Design Feature, which is to be implemented prior to the start of Project operations, is to upgrade engines on two new Chevron Suezmax ships with low emission engine technologies that result in fewer emissions than required under applicable emission control laws for ships built in 2014. As described in Draft EIR *Section 4.3.6.2.4*, Chevron is removing three Suezmax vessels from West Coast service; these will be replaced with two newly built Suezmax ships in 2014. Chevron has proposed as a Project Design Feature to upgrade the engines on the new Chevron Suezmax ships with low-emission engine

technologies that result in fewer emissions than required under applicable emission control laws for ships built in 2014. This measure shall be implemented as described in Master Response 4: Toxic Air Contaminants, under Mitigation Measure 4.3-6a(1)(ii).

2. **Cleaner Tug Boats:** Chevron shall fund and require installation of cleaner main and auxiliary engines on up to six tug boats serving the Long Wharf as well as non-Chevron facilities. Tugs are used to push barges, escort ships and barges, and assist ships and barges into berths. The Long Wharf is primarily served by six tugs. Under applicable CARB rules, four of these tugboats are required to be retrofitted with cleaner engines meeting designated Tier 2 emission standards, over a phase-in period ending as late as 2022. The remaining two tugboats are required to be retrofitted with cleaner engines meeting designated Tier 3 emission standards in 2017. Chevron shall fund the installation of new, cleaner Tier 4 main engines and Tier 3 auxiliary engines for the number of tugs required to reduce DPM, and achieve the NNI Project Objective.

As provided in Master Response 4: Toxic Air Contaminants, under Mitigation Measure 6a(1)(i), prior to the start of Project operations, Chevron shall fund and require installation of cleaner main and auxiliary engines on one tug boat serving the Long Wharf as well as non-Chevron facilities.

3. **Parcel Size Optimization:** Chevron shall increase the average parcel size (the average ship cargo volume that is delivered or picked up from the Long Wharf) to reduce the number of ship calls, and thereby reduce DPM emissions from shipping.
4. **Shore Power:** Chevron shall install electric shore power, and require one or more of the ships using the Long Wharf to use such shore power in lieu of continuing to burn diesel fuel while berthed. This measure, also referred to as "cold ironing," has been demonstrated to substantially reduce DPM-related emissions (and associated risks) from shipping (CARB 2006). This measure would require construction activities in and near the Long Wharf that would result in secondary impacts that are beyond the scope of this EIR. Before implementing this mitigation measure, Chevron shall apply to the City and other responsible agencies for necessary permits, and shall complete the environmental process required under CEQA. Implementation of this measure is not required to achieve the performance standard included in this Mitigation Measure 4.3-6a.

In the event that the Project is projected to exceed the health risk associated with the 93% Utilization Scenario, as described in Master Response 4: Toxic Air Contaminants under Mitigation Measure 4.3-6a(2), Chevron shall implement a combination of the measures i, ii, iii, or iv to reduce DPM,

inclusive of $PM_{2.5}$ to reduce health risk from all Project TAC emissions to below BAAQMD significance criteria and to ensure no net increase of health impacts from Project TAC emissions over Baseline levels. As described in Master Response 4, Mitigation Measure 4.3-6(a)(2)(iv), if, after implementing the above discussed measures, health impacts from Project TAC emissions remains above Baseline levels on a net basis, as determined by the health risk assessment required by Mitigation Measure 4.3-6b, then Chevron shall curtail Facility operations as necessary to ensure that such health risk is reduced to Baseline levels on a net basis.

1.5.2 Methodology and Results

This section explains the methodology used to estimate DPM emissions reductions associated with each of the four mitigation measures that affect TACs and the HRA risks.

Because DPM is used to estimate health risks over a 70-year exposure period for residents, future DPM emissions must be estimated. Due to regulatory changes as described in *Appendix 4.3-REG*, the DPM emissions per unit activity, or emission factor in the future will be decreasing. As described in *Appendix 4.3-SHP*, and as found in a report prepared by Chevron's contractor, ICF International (Chevron Data Transmittal #26F, 2014), the change in DPM from the Baseline took into account the fact that there would be mandated reductions in DPM emission factors for vessels with or without the Modernization Project. Accordingly, future estimated Project emissions were compared Baseline emissions developed using fleet turnover and emission factor assumptions that assure that these 40-year (i.e., worker) and 70-year (i.e., resident) estimates correctly accounted for future changes to vessel fleets (e.g. turnover to new tug engines in compliance with CARB Harbor Craft replacement requirements in 17 CCR Section 93118.5) and fuel regulations (e.g. OGV fuel sulfur content requirements per CARB regulations in 13 CCR Section 2299.2) that reduces particulate and sulfur emission factors in the absence of the Modernization Project. In this manner, it was assured that the Modernization Project did not take credit for reductions in emissions that would have resulted from current regulatory requirements even without the Project.

In addition, the emissions reductions are weighted by the 70-year age-specific sensitivity factors (ASFs) as described in footnote 21 in *Section 1.5.1.1* of *Appendix 4.3-HRA*. The incorporation of ASFs is recommended in the Office of Environmental Health Hazard Assessment's Technical Support Document (Cal/EPA, 2009) and by the BAAQMD (BAAQMD, 2010). This approach accounts for an "anticipated special sensitivity to carcinogens" of infants and children. Cancer risk estimates or emissions are weighted (i.e., increased) by a factor of 10

for exposures that occur from the third trimester of pregnancy to 2 years of age and by a factor of 3 for exposures that occur from 2 through 15 years of age. No weighting factor (i.e., an ASF of 1, which is equivalent to no adjustment) is applied to ages 16 to 70 years. As described in footnote 21 in *Section 1.5.1.1* of *Appendix 4.3-HRA*, health impacts were only evaluated for residential and worker receptors. Using the 70-year ASF-weighted emissions for worker receptors, as done in the Draft EIR, is a conservative approach since worker exposures do not have childhood ASF adjustments like those incorporated into the 70-year risk factors. In addition, health impacts to the 70-year residents are expected to be higher than those of the other populations given the length of assumed exposures and the use of the ASF adjustment.

Chevron provided emissions for shipping for the 93% Utilization Project Scenario, and the 100% Utilization Project Scenario (Chevron Data Transmittal #26D, 2014). For those scenarios where Chevron provided shipping emissions, shipping risks were directly estimated from the emissions following the methods detailed in Appendix 4.3-HRA. However, Chevron did not provide emissions for the 89% Utilization Project Scenario. To estimate shipping risks for the 89% Scenario, there were two options: (1) scaling risks based on the differences in incremental shipping volumes; or (2) scaling risks based on the ratio of total shipping volumes. It was determined that scaling risks based on the differences in incremental shipping volumes yielded more conservative (i.e., higher) risk values. Therefore, in order to estimate risks from shipping for the 89% Utilization Project Scenario and provide an appropriately high level of mitigation, risks were scaled from the 93% Utilization Project Scenario based on the differences in incremental shipping volumes between the two scenarios (93% Utilization and 89% Utilization) and the Baseline.

1.5.2.1 Suezmax Engine Upgrades

Under current regulations, the replacement of the Suezmax ships require installation of main ship and auxiliary ship engines with a level of emission control called Tier 2 under the IMO requirements (IMO 2008)⁶ for new engines that have been adopted by the EPA. These Tier 2 emissions are incorporated into the Baseline (resulting in a decrease in NO_x from these ships). As a Project Design Feature, per Mitigation Measure 4.3-6a(1)(ii), Chevron would install technologies that would lower emissions further than what is required for ships built in 2014, as follows: (1) the main ship diesel engines would be upgraded to meet the IMO

⁶ The Tier 2 MARPOL Annex IV emission standard (applicable to new engines from 2012 to 2015) requirement for a main diesel engine is 14.4 grams NO_x per kilowatt-hour for engines less than 130 rpm.

Tier 3⁷ standard (versus the required Tier 2), which would reduce NO_x emissions from the main ship engine beyond those required by regulation; and (2) auxiliary engines would be upgraded with turbogenerators to meet requirements more stringent than IMO Tier 3 standards (versus the required Tier 2), which would eliminate DPM emissions (a TAC emission) and reduce NO_x emissions. See Master Response 4: Toxic Air Contaminants.

The emission reduction features of this Project Design Feature were calculated using the same methodology as was used in the estimation of shipping emissions, as described in Draft EIR *Appendix AQ-SHP*.

The reductions in 70-year DPM emissions from this mitigation measure are 0.97 ton/year for the 93% Project Scenario and the 93% Max Light Scenario and 1.05 tons/year for the 100% Project Scenario and the 100% Max Light Scenario.

1.5.2.2 Cleaner Tug Boats

The emissions reductions from the tug boat engine replacements were estimated based on primary data for the 2008–2010 operation of the six tugs that would be replaced using the same emission estimation methodology as described for tug boats in Chevron Data Transmittal #26F (2014), accounting for emission reductions achieved by the new Tier 4 main and Tier 3 auxiliary engines. 2008–2010 transiting information for the tug boats was used to estimate the fraction of reductions that would occur within the HRA area and to allocate emission reductions to the transit legs within the HRA area. The tug boats that will be replaced are operated out of the Port of Richmond, whereas the shipping model assumes that tug boats originate from Point Blunt on Angel Island (Chevron Data Transmittal #26F, 2014). In order to maintain consistency in spatial allocations between the shipping model emissions and the shipping mitigation emission reductions, all emissions reductions that occurred on the transit leg from the Port of Richmond to the Long Wharf (Leg W) were conservatively spatially allocated to Leg Y (Angel Island to the Long Wharf), as shown in Figure A4.3-HRA-15 of Draft EIR *Appendix 4.3-HRA*. Any reduction on Leg Y would have lower risk reductions than those on Leg W. Maneuvering emission reductions were estimated based on the assumption that all Chevron ships would be assisted during maneuvering by mitigated tugs only.

⁷ The Tier 3 MARPOL Annex VI emission standard (applicable to new engines in IMO defined emission control areas from 2016 on) requirement for a main diesel engine is 3.4 grams NO_x per kilowatt-hour for engines less than 130 rpm.

Tug boat mitigation emission reductions by leg are shown in Table A4.3-MIT-9.

TABLE A4.3-MIT-9 70-YEAR WEIGHTED TUG BOAT DPM EMISSIONS REDUCTIONS BY LEG

Pollutant	Scenario	Leg X	Y	Z-NB	Z-SB	Maneuvering	Emission Reductions (tons/year, 70-year ASF-weighted)
70-year DPM	93% Project Scenario	0.49	1.51	0.19	0.19	0.35	2.73
	100% Project Scenario	0.52	1.62	0.21	0.21	0.38	2.94
	93% Light Max Scenario	0.51	1.57	0.20	0.20	0.37	2.85
	100% Light Max Scenario	0.54	1.67	0.21	0.21	0.39	3.02

Source: Chevron Data Transmittal #73 (Rev #3), 2014.

1.5.2.3 Parcel Size Optimization

Emission estimates were calculated in the shipping model by increasing parcel size by reasonable amounts. Parcel size was optimized for Chevron Suezmax, and Product ships. The parcel size as a percentage of capacity before and after the optimization is shown in Table A4.3-MIT-10.

TABLE A4.3-MIT-10 SHIP PARCEL SIZE AS A PERCENT OF CAPACITY BEFORE AND AFTER PARCEL SIZE OPTIMIZATION

Operator	Ship Type	Engine Type	Pump Type	Before Optimization		After Optimization	
				Load	Discharge	Load	Discharge
Chevron	Aframax	SSD	Steam	12.0%	0.0%	60.0%	0.0%
	Suezmax	SSD	Steam	0.0%	59.5%	0.0%	80.0%
	Product	SSD	Diesel	30.5%	17.8%	70.0%	60.0%
			Steam	51.7%	14.9%	70.0%	60.0%

Note: SSD – slow speed diesel engine

Source: Chevron Data Transmittal #73 (Rev #3), 2014.

Similarly, parcel size was optimized for Barge 2D and Barge 4D, as shown in Table A4.3-MIT-11.

TABLE A4.3-MIT-11 BARGE PARCEL SIZE AS A PERCENT OF CAPACITY BEFORE AND AFTER PARCEL SIZE OPTIMIZATION

Barge Type	Tug Engine Type	Before Optimization		After Optimization	
		Load	Discharge	Load	Discharge
BARGE1D	HSD	81.0%	0.0%	81.0%	0.0%
	MSD	87.4%	2.4%	87.4%	2.4%
BARGE2D	HSD	82.4%	7.2%	82.4%	7.2%
	MSD	72.4%	17.6%	80.0%	17.6%
BARGE3D	MSD	85.9%	0.9%	85.9%	0.9%
BARGE4D	MSD	50.1%	0.0%	80.0%	0.0%

Note: HSD = high speed diesel engine
MSD = medium speed diesel engine

Source: Chevron Data Transmittal #73 (Rev #3), 2014.

Optimized average parcel sizes were all less than average ship capacity estimates. Because of the increased parcel size for ships and barges, the annual calls will be reduced by 97 calls for ships, and by 10 calls for barges, respectively, for the 100% Light Max Scenario. Annual 70-year DPM emission reductions of 1.2 tons were estimated for the parcel size optimization mitigation for the 100% Light Max Scenario (Chevron Data Transmittal #73 (Rev #3), 2014). Table A4.3-MIT-12 shows for the 100% Light Max Scenario, estimates by ship and barge type, calls reduced, emissions available for mitigation per call, and associated 70-year DPM emission reductions. 70-year DPM emission reductions per call shown in Table A4.3-MIT-12 are estimates of emissions that are inside the HRA boundary and are available for reduction from parcel size optimization, including all low- and high-speed transit, assist and escort tug boats, and non-pumping at-berth emissions; pumping mode and stand-by tug emissions are not affected by parcel size optimization and are excluded from these estimates.

The reduction in 70-year DPM emissions from this mitigation measure are 1.105, 1.190, 1.153, and 1.224 tons/year for the 93% Project 93% Scenario, 100% Project 100% Scenario, 93% Max Light 93% Scenario, and 100% Max Light 100% Scenario, respectively.

TABLE A4.3-MIT-12 REDUCTIONS IN ANNUAL CALLS AND DPM EMISSIONS DUE TO PARCEL SIZE OPTIMIZATION

Ship Type	100% Light Max Scenario Annual Calls	Reduced Annual Calls Due to Parcel Size Optimization	DPM Emissions per Call (tons/call, 70-year ASF-weighted)	DPM Emission Reductions (tons/year, 70-year ASF-weighted)
SuezMax	145	28	0.0144	0.399
Products	208	63	0.0111	0.700
AfraMax	43	6	0.0170	0.102
BARGE2D	207	9	0.0019	0.017
BARGE4D	2	1	0.0081	0.005
Totals	605	107		1.224

Source: Chevron Data Transmittal #73 (Rev #3), 2014

1.5.2.4 Shore Power

For the Shore Power mitigation measure (i.e., Draft EIR Mitigation Measure 4.3-6a2), revised in Master Response 4: Toxic Air Contaminants as Mitigation Measure 4.3-6a(2)(iii), Chevron would be required to install additional electric power infrastructure to service the Long Wharf, and one or more of the ships using the Long Wharf to use such shore power in lieu of continuing to burn diesel fuel while berthed. This measure, also referred to as "cold ironing," has been demonstrated to substantially reduce DPM-related emissions (and associated risks) from shipping. This measure would require construction activities in and near the Long Wharf that would result in secondary impacts that are beyond the scope of this EIR. Before implementing this mitigation measure,

Chevron would be required to apply to the City and other responsible agencies for necessary permits, and the Shore Power project would be required to comply with CEQA. Because shore power is not needed to achieve the reasonably foreseeable 93% Utilization Scenario, it is considered unlikely to be implemented as mitigation.

Emission reductions are estimated for this mitigation based on the assumption that product ships owned and operated by Chevron would be the only ships that are cold-ironed at-berth. In order to utilize shore power, a ship must be compatible with the shore power electricity infrastructure. Since Chevron-owned Product ships are owned and operated by Chevron, Chevron has the ability to ensure that these ships are retrofitted, if necessary, for shore power

compatibility. Chevron-owned Product ships also account for a considerable percentage of at-berth hoteling emissions, so the use of shore power on Chevron-owned Product ships has the potential to attain significant emission reductions. Chevron-owned SuezMax ships were not considered for shore power because DPM emissions from SuezMax auxiliary engines are already controlled by the use of turbogenerators in place of diesel internal combustion engines. Chevron-owned Aframax ships account for a much smaller fraction of at-berth hoteling emissions than Chevron-owned Product ships and were therefore not considered in the shore power mitigation emission reduction estimate. It is noted that auxiliary engine emissions are reduced by cold-ironing; boiler power is not replaced by shore power.

The use of shore power at berth allows a vessel to turn off its auxiliary engines once electric power from the shore to the vessel has been established. The CARB shore power regulation⁸ allows 3 or 5 hours per call of auxiliary engine-on time for vessels complying with the CARB shore power regulation. Tankers are not required to use shore power per the CARB shore power regulation. Due to the complexities and safety considerations associated with tanker cold-ironing, it was assumed that auxiliary engines are operational for 6 hours of at-berth time per call; for the remaining time at-berth, the auxiliary engines are assumed to be turned off.

The parameters needed to estimate shore power mitigation emission reductions are as follows:

- **Hoteling time:** Chevron-owned product ship hoteling time is estimated to be 45 hours (Chevron Data Transmittal #73 (Rev #3), 2014).
- **Percent of auxiliary engine time-on at berth:** Based on the assumption of 6 hours of auxiliary engine time-on at-berth and an average of 45 hours of hoteling time per call, it was estimated that auxiliary engines would be turned on for 13% of at-berth time. It was assumed in the calculation of emission reductions that for both the hoteling mode and pumping mode, auxiliary engines would emit 13% of the emissions were shore power not used. In other words, an 87% emissions reduction due to shore power was estimated for Chevron-owned Product ship hoteling and pumping emissions.
- **Percent of Product ship emissions from Chevron ships:** Chevron-owned Product ships account for 61% of all product ship hoteling emissions and 37% of all product ship pumping emissions (Chevron Data Transmittal #73 (Rev #3), 2014).

⁸ Title 17 of the California Code of Regulations, Section 93118.3, Chapter 1, Subchapter 7.5, Airborne Toxic Control Measure for Auxiliary Diesel Engines Operated on Ocean-Going Vessels At-Berth in a California Port.

The emission reductions resulting from the shore power mitigation measures are shown in Table A4.3-MIT-13.

TABLE A4.3-MIT-13 70-YEAR WEIGHTED DPM EMISSIONS REDUCTIONS DUE TO SHORE POWER MITIGATION MEASURES

Scenario	70-year DPM Emissions (tons/year)					
	Product Ship At-Berth Emissions Without Shore Power Mitigation			At-Berth Emission Reduction Achieved By Shore Power Mitigation		
	Hoteling	Pumping	Total	Hoteling	Pumping	Total
93% Project Scenario	2.71	0.19	2.91	1.48	0.06	1.54
100% Project Scenario	2.92	0.21	3.13	1.59	0.07	1.66
93% Light Max Scenario	3.07	0.23	3.30	1.67	0.08	1.75
100% Light Max Scenario	3.18	0.24	3.42	1.73	0.08	1.81

Source: Chevron Data Transmittal #73 (Rev #3), 2014; Chevron Data Transmittal #26D, 2014.

Only DPM reductions are estimated here. However, this shipping mitigation measure also reduces NO_x, as described in *Section 4.3, Air Quality*, of the Draft EIR, and SO_x, which is not quantified for the purpose of the Draft EIR.

Table A4.3-MIT-14 summarizes the total emissions reductions resulting from shipping mitigations for the 100% Max Light Scenario (Chevron Data Transmittal #73, 2014).

TABLE A4.3-MIT-14 SUMMARY OF 70-YEAR WEIGHTED DPM EMISSIONS REDUCTIONS DUE TO SHIPPING MITIGATION MEASURES

Mitigation Measure	Emission Reductions (tons/year, 70-year, ASF-weighted)			
	93% Light Max Scenario	100% Light Max Scenario	93% Project Scenario	100% Project Scenario
Suezmax Engine Upgrades	0.97	1.05	0.97	1.05
Cleaner Tug	2.85	3.02	2.73	2.94

93% Project Scenario Shipping Mitigation Requirements

The 70-year risk under the 93% Project Scenario was 4 in a million (incorporating the Project Design Feature of the retrofitted Suezmax ships). Because the replacement of one tug, as required under Mitigation Measure 4.3-6a(1)(i) as provided in Master Response 4: Toxic Air Contaminants, reduces impacts by one fourth of the Project Scenario, the DPM reduction provided is sufficient to reduce risks to below 1 in a million. Retrofitted tugs are very effective in reducing risks because the tugs travel closer to the community than do the ships that visit the Richmond Long Wharf. In other words, the DPM that is reduced by retrofitting a single tug would result in NNI health impacts. A figure of the risks in the community that result from the retrofitting of one tug under the Project 93% Utilization Scenario, 100% hydrogen plant utilization is shown in Figure A4.3-MIT-1.

02.20.2014 U:\Chevron Renewal\ENVIRON Files\Air Quality\Risk\Figures\CVRN_A4.3-MIT-1_NNI Project 93% Cancer with One Tug.mxd

Note: Risk reductions from the installation of the PDF tank dome were not included in the HRA.
The shipping PDF (replacement of Suezmax ships) was included in the HRA.

Figure A4.3-MIT-1
Chevron Refinery Modernization Project EIR
Mitigated Cancer Risk at 93% Utilization (Project Case)
Replacing Engines for One Tug

The risks are a function of TAC emissions and location and dispersion of those TAC emissions. As described in *Appendix 4.3-HRA*, Table A4.3-HRA-18B, the DPM from marine operations, in general, and tugs in particular, drive the risk for the Project Scenario. Table A4.3-MIT-16 below shows the Baseline emissions, 70-year weighted DPM emissions for the 93% Project Scenario with and without the Project Design Feature, the Project with a single tug retrofit, the Project with multiple tug retrofits, and the Project with parcel size optimization. Note that the Project increment emissions presented in Table A4.3-MIT-16 are 70-year ASF-weighted while that presented in Table A4.3-HRA-4 are first year differences in emissions. Weighted emissions were always used for risk assessments. As shown in Table A4.3-MIT-16, the 70-year ASF-weighted DPM incremental emissions dropped from 0.99 ton/year without Project Design Feature to 0.004 ton/year with Project Design Feature, indicating the Project Design Feature's effectiveness in reducing DPM emissions. This Project Design Feature of upgrading SuezMax engines is described in *Section 1.5.2.1* of this appendix. However, as shown in Table A4.3-HRA-17b, this Project Design Feature does not reduce risks associated with DPM emissions from shipping as effectively. As shown in Table A4.3-HRA-17b, the Project incremental cancer risks associated with shipping are 4.0 in a million without Project Design Feature and 3.4 in a million with Project Design Feature.

TABLE A4.3-MIT-16 70-YEAR WEIGHTED DPM EMISSIONS FOR THE 93% PROJECT SCENARIO

Scenario	70-Year ASF-Weighted DPM Emissions (tons/year)		
	Baseline	Project	Change from Baseline
93% Project Scenario without Project Design Feature	13.47	14.46	0.99
93% Project Scenario plus Project Design Feature	13.47	13.47	0.004
One Tug Retrofit	13.47	13.02	-0.451
Parcel Size Optimization	13.47	12.39	-1.08

Note: The Baseline and Project emissions presented here include the emissions for the two additional shipping transit segments (x_e series and x_e_2 series, as shown in Figure A4.3-MIT-2 below, also called last link) beyond the HRA domain. These additional transit segments were included as a conservative measure to ensure that emissions outside the HRA zone had a de minimis impact on risk to receptors. As a result, the Project increment emissions are slightly different from what's presented in Chevron Data Transmittals #26B and #26D.

Sources: Chevron Data Transmittal #73 (Rev #3), 2014; Chevron Data Transmittal #26B, 2014; Chevron Data Transmittal #26D, 2014.

To be more specific, Figure A4.3-MIT-2 shows the locations of the DPM emissions reductions associated with the shipping Project Design Feature, which total 0.986 tons/year or 1,968 lbs/year, as shown in Table A4.3-MIT-16. Out of the 1,968 lbs/year of reductions, 1,822 lbs occur at Berth 4 and correspond to SuezMax ship hoteling. However, as shown in Table A4.3-MIT-17, the ship emissions and emission reductions were assumed to occur at a much higher height (23 meters) compared to the height of the residents and workers (1.8 meters). In addition, the high temperature (618 Kelvin (K), or 653 degrees Fahrenheit (°F)) of the exhaust compared to the ambient temperature results in additional plume rise at the release point. Consequently, the large emission reductions at Berth 4 do not translate to a correspondingly large risk reduction.

The rest of the emission reductions due to upgrading SuezMax engines are more spread out and occur at locations more distant from the community, with reduction of 70 lbs/year at the maneuvering area, 26 lbs/year on Leg Y, 29 lbs/year on Leg X, and 20 lbs/year total for the two last links. Because these emission reductions are more spread out and farther away from the community, they also do not result in a significant risk reduction.

As a comparison, Figure A4.3-MIT-2 also shows the locations of the DPM emissions reduction associated with retrofitting one tug, which is a total of 0.455 ton/year or 909 lbs/year, as shown in Table A4.3-MIT-16. Out of the 909 lbs/year of reduction, 116 lbs occur at the maneuvering area, and at a much lower release height (7.3 meters), as shown in Table A4.3-MIT-17. In addition, 502 lbs/year of reduction occur on Leg Y, not too far from the residential and worker populations, and also at a much lower release height. Consequently, because the emission reductions due to retrofitting tugs occur near the community and also emit DPM at a lower release height, these reductions are more effective in reducing the risk to NNI.

TABLE A4.3-MIT-17 MODELED SHIPPING SOURCE PARAMETERS

Emission Source Categories	Modeled Release Height (meters)	Modeled Temperature (K)
SuezMax Ships	23 (at Berth 4) or 28.8 (maneuvering or transiting)	618 (at Berth 4)
Tugs	7.3 (maneuvering or transiting)	--

Sources: Chevron Data Transmittal #26A, 2014; Chevron Data Transmittal #26C (Rev #3), 2014.

The installation of a tank dome on Tank 3225 as a Project Design Feature also reduces ROG and TAC emissions. ROG emission reductions due to the tank dome

Figure A4.3-MIT-2
Chevron Refinery Modernization Project EIR
Shipping: Emission Reductions due to PDF and NNI Mitigation

Project Design Feature are discussed in *Section 1.3* above and quantified in Table A4.3-MIT-5. Chevron recently provided new information on tank dome reductions (Chevron Data Transmittal #75 (Rev#3), 2014); however, this new information has not been verified by the BAAQMD. Because no risk reduction is assumed from the doming of tanks, any change will have no effects on risks or required mitigation.

It is noted, that the tank dome Project Design Feature and mitigation measure will also reduce TAC emissions, including emissions of benzene, toluene, xylene, ethylbenzene, cumene, naphthalene, hexane, and 2,2,4-trimethylpentane. However, because DPM emissions are the primary contributor to health risks, the reductions in TAC emissions associated with the tank dome Project Design Feature and mitigation measure have conservatively not been included in the mitigated risk result shown in Figure A4.3-MIT-1. As discussed in footnote 1 of *Appendix 4.3-HRA*, these tanks were modeled at the closest location to the residents. Were the emissions reductions modeled at this location, the reduction in health impacts would be overestimated.

100% Project Scenario Shipping Mitigation Requirements

Reaching NNI beyond this 93% Project Scenario will require implementation of additional shipping mitigation measures.

The 70-year weighted DPM emissions under the 100% Max Shipping Scenario result in risks at the Maximally Exposed Residential Receptor of 12.1 in a million (incorporating the Project Design Feature of the new, retrofitted SuezMax ships). In order to ensure that the risks are under the NNI level of 1 in a million (or one-twelfth of the risks in the Project Scenario), the risks would have been reduced to one-twelfth the risks in the 100% Max Shipping Scenario. This result would be achieved by combining the SuezMax shipping reductions already incorporated into the 93% Project Scenario, with parcel optimization and five Tugboat Retrofits in addition to the one already retrofitted under the 93% Project Scenario with mitigation. It is possible that fewer than six Tugboat Retrofits would be required to reduce the risks to NNI throughout the community. Figure A4.3-MIT-3 shows the risks that result from the mitigated 100% Utilization Scenario and Table A4.3-MIT-18 shows the changes in DPM emissions from the Baseline associated with the Project Design Feature and the shipping Mitigation Measures for the 100% Max Light Scenario.

Finally, as an additional potential measure, the EIR identifies shore power as a feasible additional mitigation measure.

Mitigation Requirements for 89% Utilization Scenario (100% Replacement Hydrogen Plant Utilization)

If the Facility operated at a utilization of 89%, for the crude unit and all gas oil gateway units and 100% hydrogen plant utilization, the unmitigated risks would be at the NNI without any mitigation, inclusive of the Suezmax Project Design Feature. Specifically, while the cancer risk is calculated to be 0.99, this rounds to a cancer risk of 1.0, or exactly the threshold for NNI. The reduction in emissions relative to the 93% Project Scenario is shown in Table A4.3-MIT-19. Figure A4.3-MIT-4 shows the risks the result for the 89% Utilization Scenario.

TABLE A4.3-MIT-19 70-YEAR WEIGHTED DPM EMISSIONS FOR THE 89% PROJECT SCENARIO WITH 100% HYDROGEN PLANT PRODUCTION

APPENDIX 4.3 - OP

OP: Refinery Operational Emissions

APPENDIX 4.3

OP: REFINERY OPERATIONAL EMISSIONS

1.1 BACKGROUND

This appendix contains details on the emissions of criteria air pollutant (CAPs) and toxic air contaminants (TACs) for the Baseline and Chevron Refinery Modernization Project (Modernization Project). A discussion of CAP emissions methods are followed by a discussion of the TAC emissions methods for the Baseline and Modernization Project subsections. Throughout this appendix, fine particulates ($PM_{2.5}$) emissions are not evaluated separately, but are instead assumed to be equal to respirable particulate (PM_{10}) emissions. This is conservative, as $PM_{2.5}$ is a subset of PM_{10} .

The methods of emissions analysis for operations were developed based on Bay Area Air Quality Management District (BAAQMD), California Air Resources Board (CARB), and United States Environmental Protection Agency (EPA) guidance; the BAAQMD's Engineering Evaluation (EE) of Project components; and extensive consultation with BAAQMD staff. As a result of consultation with the BAAQMD, a protocol for estimating Baseline and Modernization Project emissions, as well as methods for evaluating impacts from those emissions was developed. The methods presented in this appendix reflect the outcome of these meetings with the BAAQMD, and reflect the results of the consensus formed between the City of Richmond's consultants, and the BAAQMD.

After reviewing available regulatory reporting and tracking studies, for purposes of this Environmental Impact Report (EIR) and in consultation with the BAAQMD, the BAAQMD's Emissions Inventory (EI) was determined to provide the most comprehensive ongoing framework for understanding Refinery Operations emissions, and for evaluating Modernization Project emissions, within the City of Richmond.

The major sources of emissions of CAPs and TACs from Refinery Operations are stationary facilities, such as furnaces and process units used to heat, treat, and separate crude and gas oils into marketable products such as gasoline, diesel, jet fuel, and lubricants. In addition, Refinery Operations generate emissions from tanks and process components, emissions from transportation, including shipping, and to a lesser extent, rail and trucking. The locations of major operations, and therefore major sources of emissions, at the Facility are highlighted in Figure A4.3-OP-1.

This section describes existing Refinery Operations CAP and TAC emissions over the 3-year Baseline period (2008 through 2010, inclusive). Average annual Refinery Operations emissions over this 3-year Baseline period are representative of normal Refinery Operations.

In addition to describing Refinery Operations emissions during the Baseline period, this section also includes a description of the adjustments made to the Baseline consistent with the recent California Supreme Court *Smart Rail*¹ decision. In *Smart Rail*, the Court affirmed that it was always appropriate to evaluate Modernization Project impacts under CEQA against the existing setting, but that "adjustments" can and should be made to that Baseline when important for public disclosure purposes. Specifically, the Court acknowledged that where planned or adopted air pollution reduction legal mandates will result in lower facility emissions in the foreseeable future, it is appropriate for an EIR to compare Modernization Project impacts against the reduced emissions that will occur in the "adjusted Baseline" for the facility and not simply compare Modernization Project impacts to existing Baseline emission levels. The adjusted Baseline used in this EIR projects emission levels from existing Refinery Operations equipment and operations as of the proposed Modernization Project's commencement of operations in 2016.

The Baseline was adjusted in a number of ways. These are described in more detail in the descriptions that follow the calculation of the Baseline for Refinery Operations. A summary of the adjustments incorporated into the Baseline includes:

- Changes to legal air pollution limitations based on adopted rules, with known compliance deadlines
- Updates by BAAQMD's engineering staff to emission estimation factors for various Refinery Operations equipment and processing units, consistent with BAAQMD Emission Inventory management practices
- Scheduled, funded and authorized changes in Refinery Operations equipment between the end of the Baseline period (2010) and the beginning of operation (2016)

The Baseline CAP emissions from Refinery Operations are shown in Table A4.3-OP-1, and Figures A4.3-OP-2A-E, below. Additional details regarding each step in the refining process referenced in Table A4.3-OP-1 are provided in *Chapter 3, Project Description, Appendix 3, Overview of Oil Refining Process at Chevron Richmond Refinery*, and discussed further below.

TABLE A4.3-OP-1 EMISSIONS ASSOCIATED WITH REFINERY OPERATIONAL PROCESS STEPS

Process Description	Major Process Unit	Title V Emission Source Categories for Equipment and Components with Air Emissions
Other Emission Sources	Emergency diesel generators ^c	Internal combustion engines ^c
Product loading ^d	Sulfur loading Wharf loading Marketing rack	Sulfur recovery (sulfur rack), loading terminals (wharf), loading terminals (truck/rail)
Refinery Maintenance Activities	Maintenance equipment ^c	Cold cleaners ^c Paint booth ^c

Notes: API gravity = American Petroleum Institute gravity; DHT = diesel hydrotreater; FCC = fluid catalytic cracker; FCC FHT = fluid catalytic cracking feed hydrotreater; GHT = gasoline hydrotreater; H₂S = hydrogen sulfide; HNC = heavy neutral hydrocracker; HNF = heavy neutral hydrofinisher; JHT = jet hydrotreater; LNC = light neutral hydrocracker; LNF = light neutral hydrofinisher; NHT = naphtha hydrotreater; SDA = solvent de-asphalting; SRU = sulfur recovery unit; RLOP = Richmond lube oil plant; VOC = volatile organic compound

^a Due to their magnitude, emissions from the boiler plant and cogeneration plant were included in this EIR analysis, despite that there are no anticipated emission increases from these sources resulting from the Modernization Project.

^b RFG = refinery fuel gas. Emissions associated with fuel gas system are discussed in the report as furnace combustion emissions.

^c Denotes sources with emissions that are not expected to change as a result of the Modernization Project, and hence were not included in this EIR analysis.

^d Shipping emissions are discussed in *Appendix 4.3-SHP*; rail and trucking emission are discussed in *Appendix 4.3-TRANS*.

Finally, this section includes a description of how Modernization Project emissions are calculated.

Emissions from Refinery Operations vary with overall utilization: greater utilization results in greater emissions from process units at the Facility, as more fuel is required to process more feedstock.

Emissions from Refinery Operations vary based on the utilization of specific process units, which vary, in some cases, based on the type of feedstock. Higher sulfur feedstocks require greater use of the hydrogen plant and the sulfur recovery unit (SRU). These higher unit utilization levels translate into greater emissions from these units.

In its writ, the court directed the City to evaluate differences in air emissions that could be expected to occur if the Facility processed crude or gas oils with higher sulfur levels, or heavier gravity levels. In order to respond to this part of the writ, a unit rate model (URM) of Refinery Operations was developed by independent petroleum refinery experts retained by the City. Analysis of different crude blends with the URM shows that higher sulfur crude and gas oils require more hydrogen and sulfur removal processing (see *Appendix 4.3-URM*). In the example provided above, these refinery operational process units will have an increased utilization - and increased utilization of process units generally correlates to higher air emissions. The Modernization Project includes a new hydrogen plant that will be both more efficient (i.e., result in fewer emissions per unit of hydrogen produced) and larger (i.e., create more hydrogen needed to process higher sulfur feedstocks).

As further described in *Appendix 4.3-URM*, the URM estimates how the Facility's processing units are used now, and how the processing units could be used if the Modernization Project were approved. The URM generates estimates of the daily average throughput or production of various process units in relation to: (1) the amount of crude and gas oil inputs into the Facility; (2) the American Petroleum Institute (API) gravity and fractional characteristics² of the crude oil inputs; and (3) the sulfur content of the crude and gas oil inputs.

1.2 BASELINE CAP AND TAC EMISSIONS

Baseline emissions associated with the Modernization Project include emissions from the stationary sources at the Facility, such as furnaces and process

² As discussed in *Section 3, Project Description*, of this EIR, crude oil is input to the Facility and distilled in the crude unit into specific fractions of oil defined by boiling temperatures. The phrase "fractional characteristics" refers to the relative proportion of each fraction in the crude oil that enters the Facility's crude unit.

equipment, as well as emissions associated with transportation of products and feedstocks via shipping, rail and trucking. This appendix describes only emissions associated with the operation of the Facility. Shipping emissions are described in *Appendix 4.3-SHP* and rail and trucking emissions are described in *Appendix 4.3-TRANS*.

1.3 STATIONARY EMISSION SOURCES AT THE FACILITY

The main refining steps performed at the Facility are described in *Chapter 3, Project Description*, and are explained in further detail in *Appendix 3, Overview of Oil Refining Process*. Each refining step involves one or more types of processing unit (e.g., crude unit, hydrotreater) that perform a specific function, and each process unit may contain different types of equipment and components (e.g., reaction vessels, tanks, heat exchangers, compressors, pipes, furnaces, boilers, heaters). For example, the crude unit discussed as part of the Distillation Step consists of an atmospheric distillation tower, vacuum distillation tower, heat exchangers, furnaces, piping and fittings. Table A4.3-OP-1 above summarizes the relationships between the refinery operational steps discussed in the Modernization Project Description and the major process units, as well as the types of emission sources associated with each refining process unit.

Not all pieces of process equipment are emission sources. For example, the distillation columns where the crude is distilled in the crude unit consist of vessels that do not have emission stacks. The furnaces that combust refinery fuel gas (RFG) to heat the crude in heat exchangers, however, do have stacks that emit combustion products. Valves, flanges and other fittings associated with pipes and other equipment that handle the various refinery process streams are sources of fugitive emissions via small leaks.

The Facility had eight flaring events³ during the Baseline period for which causal analyses were performed consistent to the Facility's Flare Management Plan⁴ and BAAQMD regulations. Descriptions of these events, including discussions of root causes and corrective actions, are provided in Table A4.3-OP-2 below.

³ Flaring is highly episodic, and typically occurs as a result of a process upset or unit start up and shut down. Separate flare emission reports are provided to BAAQMD. As a result of stringent BAAQMD regulation, flare use is decreasing over time. Flare emissions are a very small portion of Refinery Operational emissions, which will likely further decline with the Modernization Project, as additional requirements on flare usage are being implemented. Potential changes in flare emissions are not considered quantitatively for purposes of this EIR.

⁴ Only flaring events that total 500,000 standard cubic feet per day or result in sulfur dioxide emissions greater than 500 pounds are subject to team investigations and identification of root causes that are reported to BAAQMD, consistent with BAAQMD Regulation 12-12.

TABLE A4.3-OP-2 SUMMARY OF FLARING EVENTS DURING THE BASELINE PERIOD

Date	Flares	Event Description	Root Cause	Corrective Actions
April 29, 2008	FCC, RLOP	K-1900 Surge	RLOP feed gas compressor K-1900 surged. Contributing causes included: (1) lighter off-gas from the PSA plant to K-1900 during V-1410 bleed of hydrogen and impurities; and (2) K-1900 feed gas density analyzer was out of service.	Immediate: Operators: (1) closed the bleed valve from V-1410 to the PSA plant; and (2) opened fuel gas make-up to the suction of K-1900 and the 1st stage minimum flow valve of K-1900 to heavy the feed and stop the K-1900 surging. Follow-up: Chevron: (1) updated operating procedures and engineer guidance to minimize bleeding hydrogen and impurities from V-1410 to the PSA plant; (2) added an alarm at the distributed control system to indicate E-1900 pressure drop to help operators identify if E-1900 is plugging (operators had initially suspected this as a cause); and (3) replaced the K-1900 feed gas density analyzer so that operators can verify the required feed gas specific gravity to K-1900.
April 29, 2008	FCC, North Isomax, South Isomax	Loss of GRU Pump	Isomax GRU pump motor MP-750 experienced a faulty electrical relay.	Immediate: Operators: (1) immediately cut feed in the north Isomax area; and (2) safely stabilized the debutanizer. Maintenance quickly found the faulty electrical relay, replaced it, and brought MP-750 back into service.
September 1, 2008	FCC, RLOP and South Isomax	K-1900 Unplanned Shutdown 1	RLOP feed gas compressor K-1900 shut down due to high liquid level in its knock-out drum. The causes of the high liquid level were: (1) a failed steam trap at the automatic eductor that draws liquid from the drum, leading to condensate build-up in the steam line inhibiting the performance of the eductor; and (2) a check valve did not hold, allowing backflow of steam condensate into the drum.	Immediate: Operators routed potential liquid sources away from V-1900. The second FGR compressor was started up immediately after flaring occurred to maximize the FRG system capacity. Process gases were rerouted to minimize feed gas flow to K-1900. Follow-up: Chevron: (1) added another parallel steam trap to the auto eductor; (2) repaired or replaced the failed check valve; (3) added an alarmed skin temperature indicator on the liquid outlet line from the drum (to help identify condensate backflow) and trained operators on new alarm; (4) added a routine duty to periodically run the manual eductor; and (5) created a troubleshooting job aid for the auto eductor.

TABLE A4.3-OP-2 SUMMARY OF FLARING EVENTS DURING THE BASELINE PERIOD

Date	Flares	Event Description	Root Cause	Corrective Actions
August 21, 2009	North Isomax	K-500 Unplanned Shutdown	A valve positioner associated with TKN recycle compressor K-500 malfunctioned due to build-up of silica, causing compressor shutdown. To safely control the process, operators depressured the TKN reactors, leading to flaring. TKN was taken off flare gas recovery to protect the compressors from high temperatures.	Immediate: Operators initially attempted to restart the compressor with the TKN reactors partially depressured, then followed emergency procedures to safely shut down the affected operating unit and depressure the reactor vessels. Follow-up: The valve positioner was replaced, tested and reconnected. The compressor was recommissioned and the plant restarted. The failure was investigated and the root cause determined to be build-up of silica in the positioner. Prevention measures were implemented to disassemble and inspect air supply lines to the valve positioner and the associated coalescing filter, and to evaluate the effectiveness of the filter.
November 18, 2009	RLOP, FCC and South Isomax	K-1900 Unplanned Shutdown 2	Operator inadvertently activated K-1900 emergency shutdown switch while attempting to activate an adjacent switch.	immediate: Operations immediately identified the shutdown of K-1900 and implemented start-up measures. K-1900 was returned to service within approximately 9 minutes. Follow-up: Chevron relocated the adjacent switch from the emergency control panel.
January 12, 2010	North Isomax, South Isomax, FCC and Alky	Unplanned Shutdown of TKC Unit	Packing leak at PC-4000 2nd downstream Orbit block valve.	Immediate: Operations and maintenance immediately responded to the valve leak with appropriate safety equipment. Attempts were made to stop the leak at normal and reduced operating pressures. The plant was then shut down. Follow-up: Chevron: (1) replaced the failed block valve; and (2) developed a list of Orbit valves in service in the TKC unit, and created a standing preventive maintenance action in the maintenance tracking system for those valves.
May 30, 2010	FCC, RLOP,	Emergency Shutdown of FCC	Emergency shutdown of the FCC MABT caused by high vibrations in the	Immediate: Operators: (1) attempted to restart the MABT; (2) when that proved infeasible, safely shut

TABLE A4.3-OP-2 SUMMARY OF FLARING EVENTS DURING THE BASELINE PERIOD

Date	Flares	Event Description	Root Cause	Corrective Actions
	North Isomax and Alky	Unit	expander section of the MABT resulting from catalyst adherence to the expander blades leading to uneven weight distribution on the rotating equipment.	down the FCC; and (3) maximized use of the flare gas recovery system before flaring. Follow-up: Chevron evaluated whether continuous use of disk cooling steam would prevent catalyst adherence to the MABT expander disk.
November 18, 2010	LSFO	Unplanned Shutdown of TP-460 and K-900A	Cooling water turbine pump TP-460 shut down due to loss of steam, which resulted from closing of OST valve. This led to loss of cooling water flow to No. 4 Rheniformer, accumulation of liquid in V-912A (knock-out drum for hydrogen compressor K-900A), compressor shutdown and flaring. Possible causes for the OST valve shutting include: (1) presence of condensate in the steam system; (2) turbine high speed; or (3) malfunction of the OST valve.	Immediate: Operators: (1) attempted to get spare motor-driven pump (MP-526) up to pressure; (2) restarted TP-460 within 8 minutes; (3) attempted to restart hydrogen compressor K-900A; and (4) started spare hydrogen compressor K-900. Follow-up: Chevron: (1) inspected and conducted necessary maintenance on the OST valve; (2) inspected the governor that regulates speed of the turbine and repaired or replaced as necessary; (3) evaluated the pump and compressor system design; (4) verified correct operation of the level controller on V-912A; and (5) created a procedure/job aid to prepare cooling water pump for operation that explains the steps of bleeding air out of the case.

Note: FCC = fluid catalytic cracker; FGR = flare gas recovery; GRU = gas recovery unit; LSFO = low sulfur fuel oil; MABT = main air blower turbine; OST = overspeed trip; PSA = pressure swing adsorption; RLOP = Richmond lube oil plant

To determine the impact, if any, of flaring events on ambient air quality, the dates of the flaring events listed above were compared to the ground-level monitoring data (GLM) for hydrogen sulfide (H_2S) and sulfur dioxide (SO_2). The GLM data is recorded as one-hour averages. Because the exact time of flaring could not be determined from the reports, the GLM data was evaluated for daily maximum values. Figures A4.3-OP-3A-F compare the daily maxima at each station to the dates of flaring events. The figures show that two flaring events coincided with relative peaks in the monitoring data: March 29, 2008 and August 1, 2009, both at the Gertrude Street Station.

At the time of the daily maximum H_2S and SO_2 concentrations for April 29, 2008, the wind was blowing ENE, placing the monitoring station downwind of the active flares.⁵ However, at the time of the daily maximum concentrations on August 1, 2009, the wind was blowing almost due South, well away from the monitoring site. The figures also clearly show many other peaks in concentration data that do not coincide with flaring events, and which occurred during various wind conditions. Accordingly, one flaring event may have led to higher ambient concentration during the Baseline period, but the data is not conclusive, due to a lack of information on the specific timing of the flare event.

Facility air emission permits, such as its Clean Air Act Title V permit, most directly regulate and limit emissions from the equipment within process units. In most cases, air permit limits also regulate the amount of feedstock that can be processed through a unit. For example, the Facility's crude unit has a Title V permit limit of 257,200 barrels/day, which is not being changed by the Modernization Project.

Air permits do not regulate the quality or constituents of crude and gas oils that can be processed in a particular unit. Since crude and gas oils of differing quality may require more or different processing steps, the URM (see *Appendix 4.3-URM*) was designed to evaluate the effect of processing different crude oil blends and gas oils on the utilization of the various refinery operational process units. The results of the URM demonstrate that, generally, certain Refinery Operating units such as the solvent de-asphalting (SDA) unit reach maximum permissible throughput limits at lower crude unit utilization rates for crude oils containing a greater fraction of heavier constituents. Once a specific process unit such as the SDA reaches its permitted emission limit, it can create a "bottleneck" that reduces crude unit utilization levels.

⁵ Meteorological data were collected at the Gertrude Street station (Chevron Data Transmittal #8, 2011).

Figure A4.3-OP-3F
Chevron Refinery Modernization Project EIR
Comparison of 2010 SO₂ GLM data to Flare Events

The main types of stationary emissions sources at the Facility are:

- Combustion sources (furnaces, engines, boilers, flares, cogeneration units)
- Hydrogen plant
- Loading terminals
- Some process units (cooling towers, FCC unit, miscellaneous)
- Sulfur recovery-related units (H_2S plants, sulfur removal units, sulfur loading rack)
- Storage tanks (organic liquids, inorganic liquids)
- Wastewater-related units (process drains, separators, bioreactors, containers, tanks)
- Volatile organic compound (VOC) sources (cold cleaners, fugitive components, paint booth)

Table A4.3-OP-3 summarizes the types of emissions from the main types of process units at the Facility as listed above.

Most of the process equipment is fueled by refinery fuel gas (RFG). RFG is a collection of light gases created within the Facility itself in various processing units and supplemented with natural gas. These light gases are first collected and processed in a gas-processing unit to recover any heavier components that can be refined into marketable products, and then processed to remove most sulfur compounds such as H_2S to reduce sulfur dioxide emissions from the combustion of RFG. These treated light gases are then used as fuel for the heaters and boilers that run the process units. Consumption of RFG in these process units results in both CAP and TAC emissions. Table A4.3-OP-4 lists the TAC emissions associated with RFG.

1.4 THE BAAQMD EMISSIONS INVENTORY

The BAAQMD calculates emissions of CAPs and TACs annually in its Emissions Inventory, or EI. An EI is an itemized list of emissions estimates for sources of air pollution for a specified time period. The BAAQMD requires stationary sources of emissions, such as the Facility, to provide the BAAQMD with an Annual Update on the activity, such as throughput or firing rates, of sources at the Facility.

Chevron submits an Annual Update for the Facility in which it provides information on the usage, or activity, of each source. The BAAQMD reviews that information and then uses that activity information to generate an annual EI, which is referred to as the BAAQMD EI. Due to the completeness of the EI, the fact that it was used in the Chevron Hydrogen and Energy Renewal Project EIR

TABLE A4.3-OP-3 SUMMARY OF EMISSIONS FROM FACILITY STATIONARY SOURCES

Emission Source	CAPs	TACs
RFG/NG Combustion (including flares)	NO _x , CO, PM, VOC, and SO ₂	Fuel combustion TACs ^a
FCC Process	NO _x , CO, PM, VOC, and SO ₂	FCC process TACs
Rheniformer Process	NO _x , SO ₂ , CO, and VOC	H ₂ SO ₄ ^b
Cooling Towers	VOC, PM	C ₁₂ , bromine, NH ₃ , and metals
Loading Terminals (Wharf, Marketing)	VOC	Wharf: motor gas/aviation gas fugitive TACs Marketing: motor gas/aviation gas TACs
Sulfur Recovery Claus Units (Process and Combustion)	NO _x , CO, PM, VOC, and SO ₂	Fuel combustion TACs CS ₂ , H ₂ S, H ₂ SO ₄
H ₂ S Plants	--	Hydrocarbons
Process Component Fugitives	VOC	Hydrogen plant: NH ₃ , hydrocarbons FCC FHT: DEA, H ₂ S, hydrocarbons SRU, H ₂ S plant: DEA, H ₂ S, NH ₃ Tanks: hydrocarbons
Storage Tanks	VOC	PCE Crude/Gas Oil/Motor Gas/Aviation Gas fugitive TACs
Wastewater-related Units	VOC	Hydrocarbons, H ₂ S and NH ₃
Hydrogen Plant Process	CO, VOC	Methanol, Ethanol

Consolidated Volume (2008 EIR), and the fact that it represents the most comprehensive data on the Baseline emissions according to the BAAQMD, the EI is the primary source of information relied upon in this EIR to determine Baseline emissions.

1.4.1 Estimation of Baseline CAP Emissions from Facility Stationary Sources

Consistent with the 2008 EIR, Baseline CAP emissions are based on the EI compiled by the BAAQMD (see Appendix 4.3-EI) for the Baseline years: 2008, 2009, and 2010.⁶ The EI reports contain annual-average daily emissions of five CAPs—carbon monoxide (CO), oxides of nitrogen (NO_x), PM₁₀/PM_{2.5}, SO₂, and VOCs—for every permitted and formally exempted operational source in the Facility. The EI for the Baseline years and for 2011 are contained in *Appendix 4.3-EI*. Table A4.3-OP-5 contains a comparison of the 2011 EI for the Facility with the EI for 2008, 2009 and 2010. As can be seen by a review of the information, the EI CAPs emissions for 2011 are consistent with emissions as reported in the EI for the Baseline years. Therefore, the Baseline years are representative of normal operating conditions.⁷ The Baseline did not include 2011 because there was insufficient shipping data available to appropriately characterize emissions from that year. However, a comparison of emissions from 2011, where available, indicates that emissions from that year are representative of emissions from other Baseline years. In addition, the Facility throughput, which drives shipping emissions, was also quite similar to Facility throughput in the Baseline period.

TABLE A4.3-OP-5 COMPARISON OF BAAQMD EI EMISSIONS BY YEAR

Pollutant	Emissions (Tons/Year)			
	2008	2009	2010	2011
CO	360	375	383	418
NO _x	819	867	835	877
PM ₁₀ /PM _{2.5}	252	497	455	494
SO ₂	397	471	367	374
VOC	968	878	1,011	1,319

Source: BAAQMD EI (see *Appendix 4.3-EI*).

⁶ This is consistent with the 2008 EIR in the reliance on BAAQMD's EI, though the 2008 EIR used a 1-year period (2005), instead of a 3-year averaging period (2008-2010), as the Baseline.

⁷ On August 6, 2012, a fire broke out in the crude unit at the Facility. This fire resulted in a shutdown of crude unit until its restart in March 2013. During the crude unit shut down the Facility continued to process gas oil and other feedstocks, but did not process crude oil. Accordingly, during the nearly seven month period when the crude unit was not operating, the Facility did not operate in a manner similar to that which occurred during the Baseline period. For this reason, this EIR does not use include 2012 or 2013 within the Baseline period.

The emissions listed in BAAQMD's EI exceed the Title V permit limits for two pollutants for the fluid catalytic cracker (FCC): PM₁₀, and VOC. The PM₁₀ emissions for the FCC listed in the Title V permit are 92 tons/year. The EI listed emissions of 94, 343, and 287 tons/year for 2008, 2009, and 2010, respectively. Similarly, the VOC emissions listed in the EI were 29, 29, and 24 tons/year for 2008, 2009, and 2010. These emission rates are also in excess of the Title V permit limit of 6.1 tons/year. This is discussed for each pollutant further below.

The Chevron FCC unit Title V permit contains the requirement that compliance with the PM10 limit be measured quarterly using EPA Method 5B. EPA Test Method 5B is designed to measure non-sulfuric acid particulate matter. Specifically, EPA 5B results do not include sulfuric acid but do include sulfate salts that condense above 320 degrees Fahrenheit (°F). Using EPA Method 5B, Chevron measured the FCC's emissions at 14 tons/year, below the permit limit of 92 tons/year.

In 2009 and 2010, the BAAQMD conducted two source tests where an impinger train, which is equipment designed to collect vapor phase particulates, was included at the end of the standard EPA method 5B sampling train. The impinger train was used to collect particulate matter that condenses between 320°F and ambient conditions. The BAAQMD measured PM₁₀ emissions using this method and derived an emission factor of 2.3 pounds (lbs)/ton of coke burned. As a result of those two source tests, and the activity information filed by Chevron, the BAAQMD estimated emissions to be much higher than emissions estimated using the EPA methods specified in the Chevron FCC unit Title V permit and used by Chevron.

Because the test method used by the BAAQMD is not the same test method used to evaluate compliance in the Title V permit, Chevron remains in compliance with its Title V permit, even though the emissions as calculated in the EI are above the Title V permit limit. In addition, because the source test used by the BAAQMD captures more information about PM₁₀ emissions than does the EPA Method 5B, the PM₁₀ emissions value based on the BAAQMD source test and contained in the EI will be used to represent PM₁₀ emissions for purposes of this EIR in the Baseline.

For VOCs, Chevron filed a permit application in September of 2010 to revise the VOC limit to 25.7 tons/year because Chevron believed the current limit may have been established using unreliable test data. (See September 22, 2010 Application to BAAQMD). Subsequent to the permit application, one source test conducted by Chevron in October 2010, indicated that VOC emissions were in excess of the Title V permit limit of 6.1 tons/year. The permit application is pending with the BAAQMD. Based upon consultation with the BAAQMD, the EI emissions, which are

in excess of currently permitted limits, but within the limits specified in Chevron's pending permit application, are used for purposes of this EIR for the Baseline.

1.4.1.1 Ongoing Refinery Operations Monitoring

The Facility has several continuous emissions monitoring devices, called CEMs, installed in its furnace stacks. Depending on the source, these devices measure concentrations (in ppm) of CO, NO_x, or SO₂. In most cases, the concentration measurements are combined with flow rate calculations to calculate mass emissions in lbs/day. Chevron submits this data to the BAAQMD on a monthly basis, and uses it to determine compliance with emissions permit conditions.

1.4.1.1.1 US EPA

The EPA compiles a National Emissions Inventory (NEI) for CAPs and hazardous air pollutants (HAPs) from stationary and mobile sources triennially, based primarily on emission estimates and models using data provided by state, local and tribal air agencies, and using supplemental data developed by EPA. 2008 CAP emissions estimates for Refinery Operations from the EPA NEI are summarized in Table A4.3-OP-6.

**TABLE A4.3-OP-6 SUMMARY OF 2008 CAP EMISSIONS FOR
REFINERY OPERATIONS FROM NEI DATABASE**

Pollutant	2008 Emissions (Tons/Year)
NO _x	826
SO ₂	1,697
VOC	1,046
CO	547
PM ₁₀	209

Source: EPA, 2008.

1.4.1.1.2 State Reporting

In California, the Air Toxics "Hot Spots" Information and Assessment Act (Assembly Bill [AB] 2588), which was enacted in 1987, requires stationary sources to report the types and quantities of certain substances routinely released into the air. The goals of AB 2588 are to collect emission data, to identify facilities having localized impacts, to ascertain health risks, to notify

nearby residents of significant risks, and to reduce those significant risks to acceptable levels.

1.4.1.1.3 Other Monitoring and Reporting

Local regulations also require monitoring and reporting of emissions. One such regulation--Regulation 9 Rule 10, which was adopted by BAAQMD on January 5, 1994 and subsequently amended by BAAQMD on July 17, 2002—imposes a refinerywide average NO_x emissions limit on refinery boilers, steam generators and process heaters (excluding CO boilers) that were permitted prior to the adoption of the rule. The rule also imposes a specific (not average) NO_x emission limit on all CO boilers. On a quarterly basis, facilities subject to the requirements of the rule are required to submit to BAAQMD a summary of the data (e.g., CEMs or equivalent parametric monitoring system) used to demonstrate compliance.

Some monitoring and reporting requirements from BAAQMD also appear in existing Chevron permits. For example, monthly compliance reports are required by Chevron's Authority to Construct No. 27797 for the Richmond lube oil plant (RLOP). These compliance reports include calculations of SO₂, NO_x, CO, nonmethane hydrocarbons, and total suspended particulates using equations specific to RLOP permit conditions.

1.4.2 Estimation of Baseline TAC Emissions from Facility Stationary Sources

The Baseline TAC EI was prepared from the same data source as the CAP emissions Baseline – the BAAQMD EI. While the EI for CAPs contain some groups of chemicals, such as VOCs, the BAAQMD EI for TACs contains individual chemicals, such as benzene and toluene that may fall into the broad category of VOCs. Similarly, particulate matter contains individual chemicals, such as lead and arsenic. In order to characterize the individual chemical constituents of groups of chemicals, speciation profiles are used. Speciation profiles provide estimates of the chemical composition of emissions, and are used in the emission inventory and air quality models. Regulatory agencies, such as CARB and the BAAQMD, maintain and update estimates of the chemical composition and size fractions of particulate matter and reactive organic gases, for a variety of emission source categories.

The Baseline TAC EI contains information on chemical emissions for each Facility source. In some cases, the information is presented for individual chemicals, such as benzene and toluene. In other cases, the emissions information is presented for groups of chemicals, such as crude oil or aviation gas. The ultimate use of the TACs EI is to evaluate the impact of chemical emissions on public health. While there is information on the public health impacts of

individual chemicals, there is little information on the public health impacts of blends of chemicals. Accordingly, a methodology was needed to split the groups of chemicals found in the BAAQMD EI into individual chemicals.

The BAAQMD specified that groups of chemicals be characterized as individual chemicals using the EPA's refinery Information Collection Request (ICR) document (EPA, 2011). Most groups of chemicals in the BAAQMD EI were from vapor emissions from liquids being held in tanks at the Facility. Therefore, speciation profiles of vapor emissions were required. While the EPA ICR document provided liquid speciation profiles for a number of materials, the only vapor speciation profile available was for reformulated gasoline. Reformulated gasoline contains a higher proportion of TACs in the liquid phase than other materials listed in the EPA ICR document. As a result, the vapor emissions of reformulated gas would also contain a higher proportion of TACs than other materials listed in the EPA ICR document. A comparison of the liquid profiles for reformulated gasoline and crude oil is below in Table A4.3-OP-7. While some minor components of crude oil are not present in the reformulated gasoline profile, every other constituent is present in greater amounts in reformulated gasoline.

TABLE A4.3-OP-7 COMPARISON OF EPA ICR LIQUID SPECIATION PROFILES

Chemical	ICR Liquid Phase wt%	
	Reformulated Gasoline	Crude Oil
1,3-Butadiene	--	0.0000981
n-Hexane	1.36	1.341
2,2,4-Trimethyl pentane	1.1	0.185
Benzene	0.8	0.312
Toluene	7	0.542
Xylenes (total)	7.31	0.811
Ethylbenzene	1.26	0.186
Cumene	0.19	0.108
1,2,4-Trimethyl benzene ^a	2.52	0.377
Naphthalene	0.21	0.139
Biphenyl	--	0.03
Other VOCs	78.25	95.97

Note: wt% = weight percent

^a From the EPA ICR table: 1,2,4-trimethyl benzene is not a TAC, but is a common VOC component of many refinery streams.

Source: EPA, 2011.

In the BAAQMD EI, emissions from gasoline tanks were the only partially speciated material type. Reported emissions for gasoline tanks included “gasoline” as well as benzene, toluene, ethylbenzene, and xylene (BTEX). Table A4.3-OP-8 compares the EPA ICR reformulated gasoline vapor profile to the BAAQMD EI. The table clearly demonstrates that the EPA ICR profile is conservative, as it has both more chemicals and greater fractions of the four BTEX chemicals.

TABLE A4.3-OP-8 COMPARISON OF GASOLINE VAPOR SPECIATION PROFILES

Chemical	Gasoline Vapor Phase wt%	
	ICR (Reformulated Gasoline)	EI (Unleaded Gasoline)
1,3-Butadiene	--	--
n-Hexane	1.13	--
2,2,4-Trimethyl pentane	0.3	--
Benzene	0.42	0.3
Toluene	1.09	1.02
Xylenes (total)	0.35	0.12
Ethylbenzene	0.07	0.07
Cumene	0.005	--
1,2,4-Trimethyl benzene ^a	--	--
Naphthalene	0.0003	
Biphenyl	--	--
Other VOC	96.63	98.49

Note: wt% = weight percent

^a From the EPA ICR table: 1,2,4-trimethyl benzene is not a TAC, but is a common VOC component of many refinery streams.

Source: BAAQMD EI (see *Appendix 4.3-EI*); EPA, 2011.

To be conservative, as agreed with the BAAQMD, the speciation profile for reformulated gas vapors was used to identify the chemical species in all groups of chemicals listed in the EI with emissions greater than 1,000 lbs/year increase between Baseline and Modernization Project emissions. This accounted for more than 90% of groups of chemical emissions and included unleaded gasoline, lube oil, “other hydrocarbon mixtures,” alkylate, crude oil, leaded gasoline (leaded avgas), naphtha, and distillate oil. The use of the reformulated gasoline vapor speciation profile to these 90% of the groups of chemicals results in a

conservative estimate of TAC emissions. No speciation profile was used for the balance of the groups of chemical emissions.

In determining the TAC emissions Baseline, all chemicals for which data were available from the BAAQMD EI, BAAQMD EE, and the specified ICR profile were considered. As noted earlier, the TAC emissions are used to estimate the impact of emissions on public health. Accordingly, these chemicals were evaluated for inclusion in the TAC emissions Baseline inventory, consistent with the BAAQMD's Regulation 2, Rule 5 methodology for evaluating TACs from new stationary sources (BAAQMD, 2010).

1.4.3 Adjustments to Baseline Emissions

As discussed above, because new regulations and equipment changes are scheduled to be implemented before the January 2016 expected start date of the Modernization Project, and consistent with the Supreme Court decision in Smart Rail, the Baseline is the appropriate metric for evaluating the significance of Modernization Project air emissions impacts and for assuring that there is No Net Increase in CAP emissions. The Baseline will generally result in emissions that are lower than actual 2008-2010 emission levels for Refinery Operations, even if the Modernization Project is not approved.

The specific issues addressed and incorporated in the Baseline for CAPs can be found in each section below detailing the calculation of the Baseline emissions.

In consultation with BAAQMD, the EI data has been supplemented with other BAAQMD data to the extent available and applicable. In order of preference, these alternative data sources are:

- Emissions as recorded by the CEMs from 2008-2010, which were used in lieu of EI data for the Baseline
- The 2008 BAAQMD EE for the Chevron Hydrogen and Energy Renewal Project (2008 Project), which is contained in *Appendix 4.3-EE*, and which has detailed EEs for some Facility and Modernization Project components
- Updated emission factors from the BAAQMD EI itself (i.e., factors that have been updated since the Baseline period EIs originally were compiled)

Each of these three categories of adjustments to the BAAQMD EI Baseline data is further described below. There were no regulatory changes scheduled to take effect prior to 2016 that warranted adjustments to Facility stationary source CAP Emissions. The updated emission factors for the EI are contained in *Appendix 4.3-EI*.

1.4.4 Continuous Emission Monitoring Data

Many of the furnaces at the Facility have continuous emission monitoring (CEMs) to track emissions. CEMs are monitors that continually measure emissions of certain CAPs from the stacks at the Facility. CEMs monitoring is a legal requirement for certain refinery operational equipment under BAAQMD rules and regulations, as well as under the terms of Facility permits issued by BAAQMD. Chevron records the data from these monitors, and files the reports monthly with the BAAQMD (Lazarraga, 2008). CEMs are also tested at a minimum annually, and up to quarterly, in accordance with BAAQMD and EPA requirements⁸ to ensure that they are accurately measuring emissions. CEMs are in place on most furnaces to measure NO_x. CEMs on the FCC and SRU both monitor SO₂, and CEMs on the FCC, one RLOP furnace, one of two jet hydrotreater (JHT) furnaces, and both Cogen units monitor CO. A full list of CEMs at the Facility along with the pollutants monitored during the baseline years is contained in Table A4.3-OP-9, along with the emissions measured during the baseline period by those CEMs. CEMs data was determined to be more accurate than EI data, which is generally calculated, based on more generalized data sources. The original CEMs reports for the baseline period were provided in Chevron Data Transmittal #66.

FCC (all pollutants) and SRU emissions are reported as daily averages. Daily emissions from the Baseline period were summed for each year in the Baseline period, and averaged to calculate annual average emissions over the Baseline period.

For most NO_x CEMs, the CEMs report contains a measured average emission factor (in pounds of pollutant/million British Thermal Units (MMBTU) fired) and firing rate (in MMBTU/hour) for each operating day. These two values were multiplied to calculate daily emissions, which were then summed and averaged to calculate annual average emissions over the Baseline period.

⁸ Federal requirements require all CEMs to be subject to quarterly cylinder gas audits or relative accuracy audits, and annual relative accuracy test audits (RATA) (EPA, 2012). In addition, all CEMs are subject to random field accuracy tests conducted by BAAQMD.

a. Cogeneration CO data is not included in Chevron's monthly CEMS reports because there is no CO limit on the Cogeneration unit with which to demonstrate compliance.
Source: Chevron Data Transmittal #66, 2014.

For two sources (cogeneration NO_x and JHT CO), CEMs data were provided in stack gas concentration parts per million (ppm) of pollutant and percent oxygen (%O₂). Consistent with BAAQMD direction, these values were converted to emission factors by way of the EPA Method 19 “F-Factor” (EPA, 2013):

$$EF = C_d * F_d * \frac{20.9}{20.9 - \%O_{2d}} \quad \text{Equation A4.3-OP-1}$$

Where:

EF = Emission factor (lbs/MMBTU)

C_d = Pollutant concentration, dry basis (lbs/dry standard cubic feet [dscf])

F_d = F Factor, fuel-specific, (dscf/MMBTU) determined at standard conditions (20 degree Celsius (°C) and 1 standard atmosphere [atm])

20.9 = %O₂ in air

%O_{2d} = %O₂ at stack exit, dry basis

Pollutant concentrations in ppm were converted to lbs/dscf by the following formula:

$$C_d = \frac{ppm}{1,000,000} * \frac{M * P}{T * R} \quad \text{Equation A4.3-OP-2}$$

Where:

M = Pollutant molecular weight (lbs/lb-mol), used M of NO₂ for NO_x

P = Pressure (1 atm)

T = Temperature (293 K)

R = Gas constant (1.3 cubic feet atm/K lb-mol)

The emission factors calculated from these two equations were combined with firing rate data to calculate emissions. Cogeneration firing rate data were only available on an annual basis, so the resulting emission factors were averaged for each year of the Baseline period. Daily firing rate data were provided for the JHT and RLOP furnaces, so emissions were calculated via the F-Factor method, described in equations A4.3-OP-1 and A4.3-OP-2 above, using the molecular mass of CO in equation OP-2. Because CO ppm data were not available for the RLOP furnaces in January 2008, the 2008 emissions from the remaining 11 months of data were prorated (i.e., multiplied by 12/11) to represent a full year of emissions.

1.5 BAAQMD ENGINEERING EVALUATION

In September 2008, the BAAQMD conducted an EE for the 2008 Project (BAAQMD, 2008b). The EE provided Baseline and Modernization Project emission factors for sources affected by the 2008 Project, including existing Facility process units and equipment. This EE represents the most comprehensive recent

review by BAAQMD staff of process units and equipment being modified by the Modernization Project, Table A4.3-OP-10 shows the sources evaluated in the 2008 EE for the 2008 Project, and those sources which remain included in the currently proposed Modernization Project evaluated in this EIR. This table also notes when an EE emission estimate is used in lieu of the BAAQMD EI for existing Facility equipment. The EE emission estimate is always used for proposed Modernization Project components, as discussed in the consideration of Modernization Project impacts below.

TABLE A4.3-OP-10 ENGINEERING EVALUATION COMPONENTS

Source	Included in 2008 Project	Included in Current Modernization Project
Hydrogen Plant Replacement	X	X
New Hydrogen Plant Cooling Tower	X	X
New Hydrogen Plant Flare	X	X

^a The Sulfur Truck Loading Rack Replacement will be conducted as a separate, parallel project. This will occur after the Baseline; thus, for emissions calculation purposes, it is being considered as part of the Modernization Project.
Source: BAAQMD EE (see *Appendix 4.3-EE*).

These emission factors were combined with BAAQMD EI annual activity for the Baseline period to calculate annual emissions. In the case of combustion sources, the EE Emission factors were in units of lbs/MMBTU, which required conversion to be combined with EI activities given in standard cubic feet (scf)/year of fuel gas. BAAQMD provided the following high heating values (HHVs) in order to convert MMBTU into scf (Table A4.3-OP-11):

**TABLE A4.3-OP-11 BAAQMD HIGH HEATING
VALUES**

Fuel Type	HHV (BTU/scf)
Natural Gas	1,050
Refinery Fuel Gas	1,085

Note: BTU = British thermal units

Source: Personal communication with Nicholas Maiden of the BAAQMD. 11 September, 2013.

The EE provided SRU emission factors for NO_x, CO, and PM₁₀/PM_{2.5} in other units: CO and NO_x emission factors were in ppm, and PM₁₀/PM_{2.5} emission factors were in grains/scf. Both of these measurements required stack gas flow rate to calculate emissions, which was not available in the EI – EI data for the SRU was limited to furnace firing (in therms/year) and sulfur production (in long tons/year). To characterize emissions based on these EE emission factors, new emission factors in units of “tons of pollutant/tons sulfur produced” were calculated based on data in the EE, by the following equation:

$$EF = \frac{E}{S} \quad \text{Equation A4.3-OP-3}$$

Where:

EF = emission factor (tons pollutant/long ton sulfur)

E = Emissions reported in EE (tons/year)

S = Sulfur production reported in EE (tons/year)

Separate emission factors were calculated for each release point. Based on the EE, the three SRU stack gas heaters and the three thermal oxidizers are grouped into three release points, with each release point consisting each of one stack gas heater and one thermal oxidizer. These emission factors were then combined with average EI sulfur production values to calculate emissions for the Baseline (see Table A4.3-OP-12).

1.6 UPDATED EI EMISSION FACTORS

BAAQMD staff also periodically review the EI, including emission factors used to estimate Facility emissions, and make adjustments to these factors. Where a factor was adjusted since the Baseline period, or during recent BAAQMD consultations, the newer factor was used in lieu of the superseded factors included in prior EI reports.

The EI data provided by the BAAQMD contained both unabated and abated emissions. “Unabated” emissions are emissions as they would be without any control devices such as low-NO_x burners, baghouses, or scrubbers. “Abated” emissions are the emissions after they have passed through one or more such devices. If a source is connected to an abatement device, the abated emissions represent what is being released to the atmosphere. A source may be connected to multiple devices in series, in which case the abated emissions would represent the emissions after the final device; other sources may not have any abatement, in which case the abated emissions are equal to the unabated emissions.

Relationships between emission sources and abatement devices are noted in the BAAQMD data by Source ID numbers and “Train” ID numbers. A “Train” is simply a path that emissions follow from an emission source to a release point. A source in the BAAQMD EI (e.g., a single furnace) has a Source ID number and a Train ID number. An abatement device has a Device ID number and one or more Train ID numbers. This is because a single abatement device may be connected to multiple emission sources; each of these connections has its own Train ID.

At the BAAQMD’s direction, abatement factors were determined in two ways for each source. First, abatement factors were matched by Train ID number, throughput material type, and pollutant. Second, abatement factors were matched by Source ID number, throughput material type, and pollutant. For example, Source 4285 (FCC) lists A14 as a Train ID. There are no abatement devices listed for this Train ID, but there is an abatement device listed under Train S4285, which matches the Source ID. Even though “S4285” was not a listed Train ID for the source, the BAAQMD has confirmed that their database uses this form of ID matching. The general equation for calculating abated emission factors is as follows:

$$EF_A = EF_U \times AF_T \times AF_S \quad \text{Equation A4.3-OP-5}$$

Where:

EF_A = Abated Emission Factor

EF_U = Unabated Emission Factor

AF_T = Abatement Factor for Train ID (if none, 1)

AF_S = Abatement Factor for Source ID (if none, 1)

It is important to note that the updated emission factors provided by the BAAQMD were speciated, and that the updated EI emission factors do not contain one VOC factor per source. However, the abatement factors were not speciated; an abatement device that destroys or removes organic material is simply listed as having an “organics” abatement factor. In order to reproduce organic (VOC) criteria emissions, the organic abatement factor for a particular source was applied to all non-methane organic emission factors for that source (based on the raw EI data, the BAAQMD does not include methane as part of VOCs in its CAP EI). The resulting abated emission factors were then summed to calculate a single abated VOC emission factor. For example, if a source emits both benzene and toluene and is connected to a device that abates organics, the emission factor would be calculated as is shown below:

$$EF = AF \times (EF_B + EF_T) \quad \text{Equation A4.3-OP-6}$$

Where:

- EF = the updated, abated emission factor
- AF = organics abatement factor
- EF_B = unabated emission factor for benzene
- EF_T = unabated emission factor for toluene

In addition to updated emission factors, the BAAQMD also provided equations and parameters for the small set of sources at the Chevron Marketing Terminal, which were in a separate EI. Only one of these sources had any updated data: when recalculated with the provided parameters, tank S-10 (distillate oil throughput) emissions in 2008 changed from 330.6 lbs/day to 10.8 lbs/day. The BAAQMD did not indicate which parameters had been changed. The updated value of 10.8 lbs/day was incorporated into the Baseline average annual emissions.

Table A4.3-OP-13 contains all of the updated EI emission factors.

1.7 OTHER UPDATES TO THE EI

At the direction of the BAAQMD, some additional changes were made to EI emission factors and activity data to better reflect emissions during the Baseline period. The NO_x emission factor for source S-4349 (RLOP furnace) was updated to reflect a source test that was not included in the updated EF data described above. In addition, the RFG consumption of three other furnaces (S-4044, S-4333, and S-4339) were identified as incorrect by Chevron and subsequently corrected by the BAAQMD in their EI. The updated fuel consumption values for these furnaces were provided in Chevron Data Transmittal #60, 2013.

TABLE A4.3-OP-13 EI EMISSION FACTORS UPDATED AFTER 12/31/2007

Source: BAAQMD EI (see *Appendix 4.3-EI*).

If CEMs, EE, or updated EI Emission Factors were not available, the Baseline emissions estimates were set equal to the EI emissions as originally reported by the BAAQMD for the Baseline period.

As is shown in Table A4.3-OP-14, the Baseline emissions are lower than Baseline emissions for NO_x , SO_2 and VOC, but higher for CO and $\text{PM}_{10}/\text{PM}_{2.5}$.

TABLE A4.3-OP-14 EXISTING SETTING BASELINE AND ADJUSTED BASELINE CRITERIA EMISSIONS

Baseline	406	756	487	353	937

Source: BAAQMD EI (see *Appendix 4.3-EI*).

1.8 ADJUSTEMENTS TO FACILITY STATIONARY SOURCE BASELINE TACS

TACs data were selected using the same hierarchy as CAPs emissions, except that no CEMs data for TACs are available. The EE included a limited number of speciated emission factors for sources included in both the 2008 Project and the currently proposed Modernization Project. These emission factors are combined with EI emission factors as described below.

Sources and pollutants considered by the 2008 EE were limited to sulfuric acid mist from all sources that were to be shut down or modified in the 2008 Project (hydrogen plant, cogeneration plant, power plant, SRU, and catalytic reformers), as well as a full combustion profile for the SRU.

The EE did not provide full TAC calculations for most existing sources. The SRU was the only existing source that was fully evaluated. The only exception was a calculation for sulfuric acid mist from sources that were to be shut down under that evaluation: the existing hydrogen plant, the rheniformers, and the power plant. Because the EE did not contain a full combustion TAC Profile for these sources, and because the EI did not include sulfuric acid mist for these sources, the sulfuric acid mist EF from the EE was added to TAC profiles from the EI for these sources. Consistent with the BAAQMD's direction, the SRU combustion profile from the EE is substituted entirely for the EI profile.

As with CAPs emissions, TAC emission factors used in the 2008 EE are only applied to the sources included in that evaluation and which remain included as a part of the currently proposed Modernization Project. All emission factors taken from the EE are combined with the activity data from the Baseline period EIs to calculate the Baseline emissions. Tables A4.3-OP-15a and A4.3-OP-15b list all of the EE emission factors used in calculating Baseline TAC emissions.

Similar to CAPs emissions, updated EI emission factors were also used as directed by the BAAQMD. As described above for CAPs, the updated EI emission factors were speciated, while the updated EI abatement factors were not. In calculating updated emission factors for each source, any “organics” abatement factor is applied to all organic (carbon-based) compounds, and any “Particulates” abatement factor is applied to all metals and metal compounds. The full list of chemicals with calculated emission factors, as well as their abatement factor assignments (when applicable), is in Table A4.3-OP-16. If a compound was not assigned an abatement factor, such as sulfuric acid mist, the provided EI emission factor was used without modification.

If neither the 2008 EE nor updated EI emission factors are applicable, chemical emissions listed in the EI as originally reported by BAAQMD for the Baseline period are used for Baseline emissions.

1.9 MODERNIZATION PROJECT EMISSIONS

In order to assess Modernization Project Refinery Operational emissions, three categories of Modernization Project emissions changes must be evaluated and compared to the Baseline.

The first category of emission changes results from physical changes to refinery operational process units and equipment that will affect emissions (even assuming no change in utilization and feedstock quality), such as the replacement of the hydrogen plant.

The second category of emissions changes relates to the increase in emissions resulting from increased utilization at 93% and 100% (respectively) of the Facility's permitted capacity, and 100% of the new hydrogen plant capacity. During the Baseline period, the crude unit operated at an average annual rate of 89% and the existing hydrogen plant operated as needed to produce the level of hydrogen required to process Facility feedstocks. This EIR analyzes operation of the Facility, following completion of the Modernization Project, at an average utilization rate of 93% for the crude unit and gateway gas oil units.

The third category of emission changes relates to changes to the quality of the crude and gas oils being processed by the Facility, including heavier crude oils (i.e., lighter gravity crude oils) and more “sour” (i.e., higher sulfur content) crude and gas oils. This includes the potential impacts that result from changes in metals content that may occur with changes in sulfur content and gravity.

1.9.1 Estimation of Process Unit Throughputs: Crude Oil and Gas Oil

As illustrated in Figure 4.3-9 in *Section 4.3, Air Quality*, crude oil blends enter the Facility through the crude unit and are distilled by heating into various fractions. These fractions are then fed to other process units within the Facility. The amount of each fraction is specific to each crude oil feedstock that enters the crude unit. Crude and gas oil feedstocks also contain varying amounts of sulfur that must be processed and removed from the Facility’s products. Sulfur

removal requires the use of hydrogen gas produced by the hydrogen plant or catalytic reformers, and sulfur removal processing by other process units such as hydrotreaters.

The URM, as described in *Appendix 4.3-URM*, was developed to allocate crude and gas oil feedstocks to the refinery operational process units based on publicly available technical resources, and average daily Facility crude and gas oil inputs

and process unit throughputs provided by the Modernization Project applicant for 2008-2010 (the Baseline period). Such Baseline data include average crude oil fractional characteristics and the sulfur content of the Facility feedstocks during the Baseline period.

When determining the allocations of process streams for the higher sulfur crude and gas oils proposed to be handled as part of the Modernization Project, and when determining the effect of running higher and heavier gravity crudes, the URM incorporates the proposed components of the Modernization Project, including the increased throughput limits for the FCC FHT, the new hydrogen plant, the SRU modifications, and the 50,000 barrels per day (BPD) limit on the SDA throughput.

Using the refinery operational process unit utilization levels from the URM, air emission estimates were then derived based on applying BAAQMD-approved emission factors as described above for each of the process units in the URM, and for other Facility equipment for which emissions may increase with higher Facility throughput relative to the 89% crude unit utilization during the Baseline period, as described further below.

1.9.2 Facility CAP and TAC Emissions

The methods used to estimate Modernization Project emissions were developed in consultation with the BAAQMD. To estimate Modernization Project emissions, the Baseline emissions described in prior sections of this appendix were scaled to allow for the differences in unit operations between the Baseline period and the post- Modernization Project scenarios analyzed in this EIR. Emissions for each process unit included in the URM, such as the crude unit and FCC, were scaled directly by the ratio of the Modernization Project throughput to the Baseline throughput. Other sources that will be affected by the Modernization Project but are not included in the URM, such as cooling towers, were scaled by the ratio of total crude and gas oil imports from the Baseline to the Modernization Project. In general, the TAC and CAP emissions were estimated using similar methodologies. This is more fully described below.

1.10 EVALUATION OF MODERNIZATION PROJECT CAP EMISSIONS

Project CAP emissions were based on the Baseline, the BAAQMD EE, and the URM.

1.10.1 Engineering Evaluation

As mentioned in *Section 1.5* of this appendix, the BAAQMD EE includes emission factors for Modernization Project sources that were part of the 2008 Project. For

the Modernization Project sources that remain part of the Modernization Project, including the new hydrogen plant and associated cooling tower, the SRU, and low-NO_x burners on the hydrocracker and poly plant, the emissions factors from the EE were used to estimate Modernization Project emissions.

The Modernization Project includes the installation of low-NO_x Burners on the two poly plant furnaces and three hydrocracker furnaces as Project components. The EE included NO_x emission factors for the Baseline and Modernization Project scenarios for these sources, all in units of lbs/MMBTU. To calculate Modernization Project emissions from these sources, a scaling factor was applied to the Baseline emissions:

$$S = \frac{EF_P}{EF_B} \quad \text{Equation A4.3-OP-7}$$

Where:

S = Scaling factor (unitless)

EF_P = Modernization Project emission factor (lbs/MMBTU)

EF_B = Baseline emission factor (lbs/MMBTU)

This scaling factor accounted for the decreased emissions that resulted from the installation of the low-NO_x burners. This factor was applied to the Baseline emissions prior to scaling the emissions to account for different throughputs as described below. CO, PM₁₀/PM_{2.5}, SO₂, and VOC emissions from these sources were unaffected by the low-NO_x burners, and thus were calculated using the throughput scaling method described below.

As described above, EE emission factors for the Baseline SRU emissions were recalculated to be in units of tons pollutant/long ton of sulfur using Equation A4.3-OP-3. This same approach was taken for the Modernization Project emission factors. As a result, Modernization Project emissions could be calculated directly from the sulfur production given in the URM, instead of scaling from the Baseline. The Project emission factors taken from the EE are in Table A4.3-OP-17.

In addition to new emission factors for existing sources, the EE also provided emission factors for the newly constructed hydrogen plant furnaces. The emission factors listed in the EE were in units of pounds of pollutant/MMBTU; in order to calculate emissions based on hydrogen production, these emission factors had to be converted to units of lbs pollutant/million (MM) scf H₂. This was accomplished with the following formula:

$$EF' = EF \times \frac{FR_{Max}}{H_{Max}} \quad \text{Equation A4.3-OP-8}$$

Where:

EF' = Modified emission factor (lbs pollutant/MM scf H₂ produced)

EF = Original emission factor (lbs pollutant/MMBTU)

FR_{Max} = Maximum permitted firing rate per furnace (8,059,200 MMBTU/year)

H_{Max} = Maximum H₂ production for the entire plant (89,060 MM scf/year)

The maximum hydrogen production used in this conversion is from the maximum capacity in the URM (see *Appendix 4.3-URM*). This assumes that the maximum hydrogen production corresponds to the maximum firing rate. This assumption is conservative, as it maximizes the resulting emission factors in Equation A4.3-OP-8. The converted emission factors are in Table A4.3-OP-17.

The same approach was taken for the new hydrogen plant cooling water tower. Emission factors from the EE were converted by Equation A4.3-OP-8, but with the permitted maximum water recirculation rate of 36,000 gallons/minute in place of the firing rate. These emission factors are also presented in Table A4.3-OP-17.

The EE also provided emissions for sources that do not vary with refinery activity. These include the new hydrogen plant flare (S-6021), as well as various new equipment fugitive emissions. To be consistent with the EI and BAAQMD flare reports, emissions from the hydrogen plant flare were calculated only for the flare pilot, at a firing rate of 1.6 MMBTU/hour. These values are given in Table A4.3-OP-17.

Lastly, the EE contained estimates for fugitive leak emissions from new equipment that corresponded to a 15.9 tons/year permit limit (BAAQMD, 2008a). However, this permit limit included fugitive emissions from components that are no longer included in the Project, such as the rheniformer and power plant replacements. As the Modernization Project has been revised since the EE was compiled, only emission estimates for equipment still being modified in the Modernization Project were included. Those emissions are in Table A4.3-OP-17.

Consistent with the EE, Modernization Project SO₂ emissions from sources fired on RFG were limited to 49.09 tons/year.

1.10.2 Process Unit Scaling

The Baseline emissions were scaled to estimate Modernization Project emissions based on the changes that would be anticipated for each source type. Some types of sources would scale linearly with increased Facility throughput. Other types of source emissions would not change between the Baseline and the

	Wastewater treatment

Source: URM (see *Appendix 4.3-URM*); Chevron Data Transmittals #36K, 36L, and 36N (Rev#1), 2013.

For both sources scaled by plant throughput and sources scaled by total imports, the general equation is as follows:

$$E_p = E_B \times \frac{URM_p}{URM_B} \quad \text{Equation A4.3-OP-9}$$

Where:

E_p = Modernization Project Emissions (tons/year)

E_B = Baseline Emissions (tons/year)

URM_p = Unit Rate Model Project throughput (BPD)

URM_B = Unit Rate Model Baseline throughput (BPD)

1.10.3 Sources Scaled by Plant Throughput

As mentioned above, emissions from sources included in the URM were scaled based on the ratio of Modernization Project to Baseline URM throughputs. This includes plants such as the crude unit and hydrotreaters, as well as process sources such as the FCC and catalytic reformer regeneration. The hydrogen plant and SRU emissions were scaled based on hydrogen and sulfur produced, respectively.

Increased firing rate results in increased emissions. Thus, by scaling emissions with firing rates, the methodology presumes that firing rates increase proportionally to throughput. For some sources, this assumption resulted in estimated effective firing rates that exceeded their respective Title V firing rate limits. At BAAQMD's direction, emissions from several sources were limited to the amount that corresponds to their Title V firing rates. It is important to note that this does not mean that the throughput of these sources would be limited in any way. Rather, it indicates that firing rates increase at a slower rate than throughput, contrary to the conservative model assumptions. This adjustment was to ensure that emissions predictions did not exceed those that were possible under the maximum allowed firing rate. The affected sources and their restricted throughputs are listed in Table A4.3-OP-19.

A list of each unit scaled by the URM results and the relevant scaling unit are included in Table A4.3-OP-20.

1.10.4 Sources Scaled by Total Imports

Some sources will have increased emissions as Facility throughput increases but are not part of the URM. These sources include cooling water towers, the marketing rack, wharf loading, and the associated wharf emissions reduction device. Emissions from these sources were scaled by the ratio of total crude and gas oil imports (to the Facility) from the Baseline period to the Modernization Project.

1.10.5 Scaling for Storage Tanks

Storage tank emissions were also scaled by the ratio of total crude and gas oil imports, but only for the portion of emissions that varies with tank throughput. Storage tank emissions are calculated as the sum of two components: breathing (fixed) and working (variable) emissions. The BAAQMD EI only provides the total emissions for each tank and does not differentiate between breathing and working losses.

TABLE A4.3-OP-19 SOURCES WITH THROUGHPUTS LIMITED BY TITLE V FIRING RATES

Source	Baseline Firing Rate (MMBTU/year)	Baseline URM (BPD)	Title V Firing Rate (MMBTU/year)	Maximum Linear Throughput (BPD)
S-4159	261,847	36,300	414,348	57,441
S-4160	267,272	36,300	395,076	53,658
S-4167	704,527	36,300	1,007,400	51,905
S-4330	64,377	6,000	120,012	11,185
S-4333	208,128	15,400	549,252	22,000
S-4339	71,514	12,600	166,440	16,500
S-4349	109,187	6,000	144,540	7,943

To properly estimate Modernization Project emissions, the fraction of working losses was estimated and applied to all storage tanks. The working losses for each tank were then scaled upward in relation to increased Facility throughput, and then added to the breathing losses. The BAAQMD uses the EPA Compilation of Air Pollutant Emission Factors (AP-42) equations to estimate emissions from storage tanks (EPA, 1981).⁹

Chevron provided specifications for four representative storage tanks in Chevron Data Transmittal #16 (Rev #3, 2013): one each for crude oil, gas oil, gasoline and sour water. These data were used in combination with the EPA's AP-42 equations for storage tank emissions, the same equations used by the BAAQMD to estimate emissions. The equations for breathing and working losses are as follows:

$$L_S = K_S \times V^N \times P^* \times D \times M_V \times K_C \times E_F \quad \text{Equation 3 from Supplement 12 to AP-42}$$

Where:

L_S = standing (breathing) loss

K_S = seal factor, taken from AP-42 based on parameters in Chevron Data Transmittal #16 (Rev #3), 2013

V = average wind speed at tank site, 7 miles/hour (value used in BAAQMD EI)

N = seal related wind speed exponent, taken from AP-42 based on parameters in Chevron Data Transmittal #16 (Rev #3), 2013

P^* = vapor pressure function, calculated via

$$P^* = \frac{\frac{P}{P_A}}{\left(1 + \left(1 - \left(\frac{P}{P_A}\right)^{0.5}\right)\right)^2}$$

P = true vapor pressure at average actual organic liquid storage temperature, taken from AP-42 based on parameters in Chevron Data Transmittal #16 (Rev #3), 2013

P_A = average atmospheric pressure at tank location, taken from TANKS v4.09D for San Francisco

D = tank diameter, provided in Chevron Data Transmittal #16 (Rev #3), 2013

M_V = average vapor molecular weight, taken from AP-42 based on parameters in Chevron Data Transmittal #16 (Rev #3), 2013

K_C = product factor, taken from AP-42 based on parameters in Chevron Data Transmittal #16 (Rev #3), 2013

E_F = secondary seal factor, taken from AP-42 based on parameters in Chevron Data Transmittal #16 (Rev #3), 2013

⁹ The equations for storage tank emissions provided with the EI for the Marketing Terminal are consistent with Supplement 12 to AP-42.

$$L_W = \frac{0.943 \times Q \times C \times W_L}{D}$$

Equation 4 from Supplement 12 to AP-42

Where:

 L_W = working loss

Q = average throughput, taken from the EI for the tanks specified in Chevron Data Transmittal #16 (Rev #3), 2013

C = shell clingage factor, taken from AP-42 based on parameters in Chevron Data Transmittal #16 (Rev #3), 2013

 W_L = average organic liquid density, taken from AP-42 based on parameters in Chevron Data Transmittal #16 (Rev #3), 2013

D = tank diameter, provided in Chevron Data Transmittal #16 (Rev #3), 2013

Using these equations, a working loss fraction was calculated for each of the four tanks. These four working loss fractions were applied to each storage tank with the matching material, as listed in the EI. Similar materials were also matched, based on a list provided by Chevron, presented in Table A4.3-OP-21. If a storage tank contained a material other than the ones listed, the maximum calculated working loss percent was used. Once a working loss percent was chosen, Modernization Project emissions for each storage tank were calculated with the following equation:

$$E_F = E_B \times F_W \times \frac{URM_F}{URM_B} + E_B \times (1 - F_W)$$

Equation A4.3-OP-10

Where:

 E_F = Future case emissions E_B = Baseline EI emissions F_W = Working loss fraction URM_F = Future URM crude and gas oil imports URM_B = Baseline URM crude and gas oil imports

Total crude and gas oil imports were used as a surrogate for URM scaling for all tanks. For tanks containing materials that are not similar to crude oil, gas oil, gasoline, or sour water, the most conservative working loss fraction (i.e., for a tank containing gas oil) is applied for scaling purposes. The throughput materials that were assigned a specific working loss fraction are in Table A4.3-OP-21. The EIR's tank emission estimation methodology, like the other Modernization Project emission estimation methodologies, was reviewed with the BAAQMD as part of the EIR preparation process.

TABLE A4.3-OP-21 PERCENT WORKING LOSS USED FOR SPECIFIC MATERIALS

Modeled Material	Throughput Material	Percent Working Loss
Gas oil	Gas oil	95%
Crude oil	Crude oil	81%
Gasoline RVP 7 ^a	Alkylate	15%
	Gasoline - leaded	15%
	Gasoline - unleaded	15%
	Isooctane	15%
	Naphtha	15%
	Paraffins - C3+	15%
Gasoline RVP 10 ^{a,b}	Sour water	2%

^a Chosen because AP-42 vapor pressure most nearly approximated Chevron provided vapor pressure.

^b Sour water tanks are modeled as gasoline.

Source: Transmittal #16 (Rev #3), 2013

1.10.6 Removal of Existing Equipment Fugitives

Because the Modernization Project entails the shutdown and removal of the existing hydrogen plant, fugitive emissions associated with the existing hydrogen plant were subtracted from the Modernization Project emission totals. Chevron provided estimates for these emissions for the Baseline in Chevron Data Transmittal #21C, 2012. These estimates came from Chevron's leak detection and repair system. At the BAAQMD's direction, "pegged" leaks (leaks detected at greater than 10,000 ppm) were removed from the emission totals. Chevron provided measurement data for pegged leak components in Chevron Data Transmittal #49, 2013.

At the BAAQMD's direction, each pegged leak was assumed to have been leaking for half of the measurement frequency, which was 1 year (i.e., assumed 6-month leaks). Emission factors were taken from the CAPCOA guidance for fugitive emissions (CAPCOA, 1999). The resulting emissions reductions are presented in Table A4.3-OP-22.

TABLE A4.3-OP-22 ESTIMATION OF FUGITIVE EMISSIONS FROM THE EXISTING HYDROGEN PLANT

Category	Emissions (tons/year)
Leak Detection and Repair System Emissions	3.38
Estimation of pegged leaks	1.33
Total Project Emissions Reduction	2.05

Source: Chevron Data Transmittals #21C (2012) and #49 (2013).

1.10.7 Source Emissions that do not vary with the Modernization Project

The BAAQMD EI includes emissions for many sources that are not expected to change with Facility throughput generally, or Modernization Project changes more specifically. These sources include the cogeneration plant and power plant boilers, diesel engines (e.g., emergency generators, lights), portable sealed storage containers, wastewater treatment plant, maintenance shops, flares, and certain product loading racks (e.g., non-retail gasoline). A list of these sources, as well as the reason that no change is expected with the Modernization Project is found in Table A4.3-OP-23.

1.11 EVALUATION OF MODERNIZATION PROJECT TAC EMISSIONS

TAC emissions were estimated using generally the same methodology as CAP emissions. In estimating TACs emissions, TACs data from the BAAQMD EI and EE were considered. These TACs were evaluated for inclusion in the TAC emissions estimation based on whether there were quantitative toxicity data published by the California Environmental Protection Agency under the Office of Health Hazard Assessment (Cal/EPA, 2013). This is consistent with how TACs are chosen for inclusion in the BAAQMD's Regulation 2, Rule 5: New Source Review of TACs (BAAQMD, 2010).

Consistent with the approach described in estimating the Baseline TAC emissions, materials where emissions were not presented as individually identifiable compounds, such as crude oil, unleaded gasoline, and other hydrocarbons, were conservatively evaluated using the speciation profile for gasoline vapor provided in the EPA ICR document.

TABLE A4.3-OP-23 FACILITY SOURCES FOR WHICH EMISSIONS ARE EQUAL TO BASELINE EMISSIONS AND DO NOT VARY WITH THE MODERNIZATION PROJECT OR INCREASED FACILITY UTILIZATION LEVELS

Source Type	Reason for Not Scaling
Component Fugitives	Emissions from process components such as valves and flanges are dependent on the material in the pipe and not flow through the pipe.
Electricity Generation	It is reasonably foreseeable that electricity and steam generation would not be affected by the Modernization Project because of inherent energy efficiencies and power/steam generation from Project components.
Flares	Flare pilots operate continuously independently of throughputs. Planned flaring events such as startup and shutdown, as well as emergency flaring events, occur periodically but are also independent of the quantity of Facility throughputs.
Other Product Loading	The unrefined and refined wax loading racks, point orient wharf, asphalt tank truck loading racks, and main tank car loading rack have all been removed from service. The heavy oil trans-loading rack and non-retail gasoline dispensing facility are used internally by Chevron and are not related to Facility throughputs.
Maintenance Shops	Maintenance shops conduct routine operations that are independent of Facility throughputs, and are not expected to increase (and may well decrease) with the modernization of the Facility by the Modernization Project's process unit and equipment modifications.
Portable Storage Containers	These containers are used internally by the Facility for operations not affected by Facility throughputs, and are sealed.
Wastewater Treatment	The volume of wastewater produced in the Modernization Project has been reduced to the same level as the Baseline through Project Design Features, as discussed further in the <i>Section 4.9, Hydrology and Water Quality</i> .

1.11.1 Engineering Evaluation

The BAAQMD EE considered post-Modernization Project TAC emissions from the new hydrogen plant, including the cooling tower and flare pilot, the SRU, and new equipment fugitives. Emission factors for the hydrogen plant, cooling tower, and SRU were converted to be compatible with the URM via Equation A4.3-OP-8, above. SRU emission factors were converted using a maximum sulfur production of 600 long tons/day, due to the use of oxygen enrichment as a means of limiting combustion. The resulting emission factor profiles are in Table A4.3-OP-24. As with the Baseline, the sulfuric acid mist emission factors in Table A4.3-OP-15b were also incorporated with EI emission factors for the power plant and rheniformers.

Source: BAAQMD EE (see *Appendix 4.3-EE*).

As with CAP emissions, only fugitives from equipment still part of the Modernization Project were included; the fugitives associated with the continuous catalytic reformer and cogeneration 3 units were excluded. The new hydrogen plant flare pilot and equipment fugitive emissions do not vary with any throughputs. Thus the TAC emissions presented in the EE for these sources could be used directly here. The only adjustment made to the hydrogen plant flare pilot emissions was that they were scaled down to represent only activity associated with pilot and purge. This was done with the following equation:

$$E'_i = E_i \times \frac{FR_p \times 8760}{FR} \quad \text{Equation A4.3-OP-11}$$

Where:

E'_i = scaled emissions for pollutant 'i' (lbs/year)

E_i = originally reported emissions for pollutant 'i' (lbs/year)

FR_p = permit limit firing rate for pilot/purge only (1.6 MMBTU/hour)

8760 = hours/year

FR = firing rate originally used in the EE (MMBTU/year)

The speciated emissions for these sources are presented in Table A4.3-OP-25.

1.11.2 Scaling of TAC Emissions

The scaling of Modernization Project TAC emissions was conducted identically to the scaling for CAPs, as described above.

1.12 FACILITY MODERNIZATION PROJECT CAPS EMISSIONS

The Facility CAPs emissions, calculated as described above are presented for the Modernization Project crude blend as well as a variety of other crude blends in Table A4.3-OP-26. Each of the four main crude blends (Modernization Project, sourest, heaviest, and lightest) are presented at 93% and 100% gateway unit utilization, as well as URM specified and maximum hydrogen production. Table A4.3-OP-26 also includes the three “bookend” maximum crudes (sour, heavy, and light).

Chevron will install one tank dome as a Modernization Project Design Feature, on Tank 3225. The emissions reductions from the tank dome were estimated by modeling the post- Modernization Project throughput for tank with the EPA's TANKS v4.09D program, as the program will be used to determine emissions reductions for all tank domes during the permitting process. The tank was modeled at the projected post-Project throughput, with and without the tank dome, to determine the reduction. The tank dome will reduce VOC emissions by 2.1 tons per year (A4.3-MIT-11). The Facility CAPs emissions with the tank dome Project Design Feature are presented in Table A4.3-OP-27.

TABLE A4.3-OP-25 TAC EMISSIONS FROM THE ENGINEERING EVALUATION

Chemical	Emissions (lbs/year)

1.13 FACILITY MODERNIZATION PROJECT TACS EMISSIONS

The Facility TACs emissions, calculated as described above are presented for the Baseline as well as the four Project HRA Cases (see *Appendix 4.3-HRA*) in Table A4.3-OP-28.

Facility TAC emissions with the single tank dome Project Design Feature are in table A4.3-OP-29. Reductions in TAC emissions were estimated by speciating the 2.5 ton/year VOC reduction with the EPA ICR profile for reformulated gasoline, described above in Table A4.3-OP-7, as the BAAQMD EI lists “recovered oil” as the throughput material for Tank 3225.

1.14 FACILITY CAP AND TAC MODERNIZATION PROJECT DESIGN FEATURES

Several components of the Modernization Project have been proposed to reduce air emissions under the Modernization Project's proposed 93% Refinery Utilization levels. The following sections contain a summary, by individual CAP, of the various Modernization Project components that contribute to the Modernization Project's No Net Increase Project objective.

TABLE A4.3-OP-26 CAP EMISSIONS BY CASE, WITHOUT PROJECT DESIGN FEATURES

Emissions Case	Emissions (tons/year)					Change from Baseline (tons/year)				
	CO	NO _x	PM ₁₀ /PM _{2.5}	SO ₂	VOC	CO	NO _x	PM ₁₀ /PM _{2.5}	SO ₂	VOC
Baseline	406	756	487	353	937	--	--	--	--	--
Project Crude Blend, Max Hydrogen Production, 100% Utilization	462	757	516	350	988	56	1	29	-3	51

1.14.1 Nitrogen Oxides

1.14.1.1 Replacement Hydrogen Plant and Associated Emission Controls on the Unit's Furnaces

The Modernization Project includes the replacement of the Facility's existing hydrogen plant. As described in *Chapter 3, Project Description*, the new plant will be equipped with newer technology including pressure swing absorption that is less fuel intensive and results in reduced fuel usage per unit of hydrogen produced, and subsequently lower NO_x emissions, compared to the existing plant. Additionally, the three existing hydrogen plant furnaces will be replaced by two new furnaces. Currently, only one of the three existing furnaces is equipped with selective catalytic reduction emission controls, which converts NO_x to nitrogen and water. Both replacement furnaces will meet Best Achievable Control Technology requirements and be equipped with selective catalytic reduction and low-NO_x emitting burners, which control the fuel and air mixture in the furnace to reduce NO_x formation.

1.14.1.2 Emission Controls on the Existing Sulfur Recovery Units

The SRU contains burners and furnaces that provide the heat required to complete the sulfur removal process. The Modernization Project replaces existing burners with "ultra low-NO_x emitting burners" and fuel-induced recirculation, which lowers NO_x emissions by recirculating a portion of the exhaust gas into the incoming fuel. These replacements are required to meet BAAQMD emission reduction requirements and help offset increases in NO_x that would otherwise occur to increased utilization at the SRUs.

1.14.1.3 Replacement with of Low- NO_x Burners for Five Existing Furnaces

The Modernization Project also includes the installation of low-NO_x burners on five furnaces, three in the hydrocracker unit and two in the polymerization unit. These new burners will effectively reduce NO_x emissions by reducing the NO_x formed as part of the combustion process, helping to reduce the Facility's overall NO_x emissions.

1.14.1.4 FCC FHT Alterations

As part of the Revised Modernization Project, heat exchangers and other equipment used to transfer heat energy at the FCC FHT unit will be modified to improve energy efficiency, allowing for additional throughput without requiring additional permitted heat input at the unit's furnaces, helping to control NO_x emissions.

1.14.2 Carbon Monoxide

1.14.2.1 Emission Controls on the Existing Sulfur Recovery Units

As discussed above, the Modernization Project includes new low-NO_x Burners equipped with fuel-induced recirculation, as well as other minor modifications in the SRU stack heaters that will improve the mixing and combustion efficiency of the units, which reduces CO emissions. The existing thermal oxidizers at the SRUs will also operate at a higher minimum operating temperature, further reducing CO emissions.

1.14.2.2 FCC FHT Alterations

Also as described above, the Modernization Project includes heat exchangers and other equipment used to transfer heat energy at the FCC FHT unit. These modifications improve energy efficiency, allowing for additional throughput without requiring additional heat for the unit's furnaces, and thereby lowering CO emission rates for this process unit.

1.14.3 Sulfur Dioxide

1.14.3.1 Collection and Treatment of Refinery Process Gas

As discussed above, the Facility's process heaters use a gaseous fuel called RFG (which consists of refinery process gas plus natural gas) to produce the heat needed for refinery operational process units. The Modernization Project involves the collection of most of the refinery process gas (RPG) stream to be used as a feedstock in the new hydrogen plant, in lieu of using imported natural gas for the hydrogen plant. Prior to using the RPG stream as a hydrogen plant feedstock, the sulfur from the RPG will be further removed to less than 100 parts per billion using a zinc oxide scrubber.

After the Modernization Project is completed, additional imported natural gas (which is already low in sulfur) will be mixed with the RPG not used in the hydrogen plant. The treatment of the RPG for use in the hydrogen plant, and the subsequent decrease in the ratio of RPG to natural gas in the use of this mixture of RPG and natural gas in other refinery operational process units, will result in a net decrease in overall SO₂ emissions from the Facility combustion sources.

1.14.3.2 FCC FHT Alterations

As discussed above, heat exchangers and other equipment used to transfer heat energy at the FCC FHT unit will be modified to improve energy efficiency, allowing for additional throughput without requiring additional heat for the unit's furnaces, thus reducing fuel use. This reduction in fuel results in lower SO₂ emissions.

1.14.4 Respirable Particulate Matter (<10 microns)

1.14.4.1 Replacement Hydrogen Plant

The Modernization Project includes the replacement of the Facility's existing hydrogen plant. As described in Section 4.3.6.2.1.4.4 the new plant will be equipped with newer technology that is less fuel intensive and results in reduced fuel usage per unit of hydrogen produced. This modification also lowers PM₁₀ emissions from combustion.

1.14.4.2 Wet Electrostatic Precipitators

The Modernization Project includes the installation of wet electrostatic precipitators, which use electric charges to remove small liquid droplets and particulates from exhaust gas streams, on each of the existing SRUs. These emission reduction devices are required under applicable BAAQMD requirements and will reduce PM₁₀ emissions from these sources.

1.14.4.3 FCC FHT Alterations

As described above, heat exchangers and other equipment used to transfer heat energy at the FCC FHT unit will be modified to improve energy efficiency, allowing for additional throughput without requiring additional heat to the unit's furnaces, thus reducing fuel use. This reduction in fuel results in lower PM₁₀ emissions.

1.14.5 Volatile Organic Compounds

1.14.5.1 Replacement Hydrogen Plant

As described in Section 4.3.6.2.1.4.4, the new hydrogen plant will be equipped with newer technology that is less fuel intensive and results in reduced fuel usage per unit of hydrogen product. The reduced fuel use results in less VOC emissions compared to the existing plant.

1.14.5.2 Emission Controls on the Existing Sulfur Recovery Units

As described above, the Modernization Project's new low-NO_x Burners and other minor stack modifications in both the SRU combustion sources that will improve the mixing and combustion efficiency of the units, which reduces VOC emissions. Furthermore, Chevron has agreed to increase the minimum temperature limitations of the existing thermal oxidizers at the SRUs, resulting in a greater reduction in VOC emissions. An increase in minimum combustion temperatures at the SRU will reduce the VOC emissions, as more destruction of VOCs will occur at higher temperatures.

1.14.5.3 FCC FHT Alterations

As part of the Revised Modernization Project, heat exchangers and other equipment used to transfer heat energy at the FCC FHT unit will be modified to improve energy efficiency, allowing for additional throughput without requiring additional permitted heat input at the unit's furnaces, helping to control VOC emissions.

The Emission Reduction features of this set of Project Design Features were reviewed by BAAQMD in its EE prepared for the 2008 Project, and the emission factors and permit limits for these Project Design Features have already been integrated into the emission estimates used to calculate CAP emission from the Facility.

APPENDIX 4.3 - PHYS

PHYS: Physical Setting

APPENDIX 4.3

PHYS: PHYSICAL SETTING

Air quality depends upon both the rate and location of pollutant emissions. Atmospheric conditions such as wind speed, wind direction, and air temperatures interact with features of the landscape to determine the movement and dispersal of air pollutants and consequently affect air quality. This appendix describes the physical setting for the Modernization Project through a discussion of regional and local information related to climate, meteorology, and air pollution conditions.

1.1 REGIONAL AIR QUALITY BASIN

The City of Richmond is located in the nine-county San Francisco Bay Area in west Contra Costa County. It is located within the San Francisco Bay Area Air Basin (SFBAAB) under the jurisdiction of the BAAQMD. The SFBAAB includes all of Alameda, Contra Costa, Marin, Napa, San Francisco, San Mateo, and Santa Clara Counties, the southern portion of Sonoma County, and the southwest portion of Solano County. The SFBAAB covers approximately 5,540 square miles of terrain consisting of coastal mountain ranges, inland valleys, and the San Francisco Bay. The SFBAAB is generally bounded on the west by the Pacific Ocean, on the north by the Coast Ranges, and on the east and south by the Diablo Range.

The City of Richmond is located in the Northern Alameda and West Contra Costa County climatological subregion of the SFBAAB. This climatological subregion stretches from Richmond to San Leandro. Its western boundary is defined by the Bay and its eastern boundary by the Oakland-Berkeley Hills. The Oakland-Berkeley Hills have a ridgeline height of approximately 1,500 feet, a significant barrier to air flow. The most densely populated area of the subregion lies in a strip of land between the Bay and the lower hills.

Richmond, the northern-most city of this zone, is 10 miles northeast of the Golden Gate. At the Bay Area Air Quality Management District's (BAAQMD's) San Pablo meteorological station, 4½ miles west-northwest of downtown Richmond, the prevailing direction is south-southwesterly with over 50% of the winds coming from the south through southwest sector. The average wind speed at this station is 11 miles per hour (mph).

In the SFBAAB, marine air traveling through the Golden Gate, as well as across San Francisco and through the San Bruno Gap, is a dominant weather factor. The Oakland-Berkeley Hills cause the westerly flow of air to split off to the north and south of Oakland, which causes diminished wind speeds. The prevailing winds

for most of this subregion are from the west. At the northern end of the region, near Richmond, prevailing winds are from the south and southwest. The prevailing wind patterns in the SFBAAB are shown in Figure A.3-PHYS-1.

As shown in Figure A4.3-PHYS-2, two surface meteorological stations were found in the vicinity of the Facility: one is the station maintained by the Facility located just south of the western end of the W. Gertrude Avenue (“Gertrude station”) on the Facility property. The other station is a National Climate Data Center (NCDC) station (AWS ID 994036) located on the Refinery Pier just south of Highway 580 (“Pier station”).

Based on the pattern of wind direction frequencies (i.e., windroses) depicted in Figure A4.3-PHYS-2, the wind conditions between the two stations are generally similar; however, there are a few notable differences. One difference is that low wind speeds occur more frequently at the Pier station than at the Gertrude station. In addition, wind blowing from the northwest direction happens more frequently at the Pier station than at the Gertrude station. The more frequent northwest wind at the Pier station can be explained by the “channeling” effect of the terrain just north of the Pier station, which features a mountain ridge running from Point San Pablo to south of the Site boundary, separating the two stations. The Gertrude station represents meteorological conditions on the north side of the mountain ridge, while the Pier station represents meteorological condition on the south side of the mountain ridge, due to the effect of terrain on the meteorology in that area.

1.2 TOPOGRAPHY, METEOROLOGY, AND CLIMATE

The SFBAAB climate is dominated by a strong, semi-permanent, subtropical high-pressure cell over the northeastern Pacific Ocean. Climate is also affected by the moderating effects of the adjacent oceanic heat reservoir. Mild summers and winters, moderate rainfall and humidity, and daytime onshore breezes characterize regional climatic conditions in the San Francisco Bay Area (Bay Area). In summer, when the high-pressure cell is strongest and farthest north, fog forms in the morning and temperatures are mild. In winter, when the high-pressure cell is weakest and farthest south, occasional rainstorms occur.

Ambient concentrations of air pollutant emissions are determined by the amount of emissions released by pollutant sources and the atmosphere’s ability to transport and dilute such emissions. Natural factors that affect transport and dilution include terrain, wind, atmospheric stability, and the presence of sunlight. Existing air quality conditions in the project area are determined by such natural factors as topography, meteorology, and climate in addition to the amount of emissions that the existing sources of air pollutants release. The

 Source: Hayes et al, 1984

Figure A4.3-PHYS-1
 Chevron Refinery Modernization Project EIR
 Prevailing Winds Near Richmond

environmental factors that affect ambient air pollutant concentrations are discussed separately.

1.2.1 Temperature Inversions

Temperature inversions, also called thermal inversions, describe areas where the normal decrease in air temperature with increasing altitude is reversed and air at higher altitudes is warmer than the air below it. Inversion layer thicknesses can be anywhere from under 100 feet to over thousands of feet. Thermal inversions limit the vertical dispersion of air pollutants, and can trap pollutants close to the ground. These inversions occur most often when a warmer, less dense air mass flows over colder denser air mass close to the ground. The highest air pollutant concentrations in the Bay Area generally occur during such inversions, of which there are two types: 1) subsidence inversions – a regional phenomenon that is most common in the Bay Area during summer and fall, when descending warmer air from the subtropical high pressure cell centered over the Pacific Ocean caps the cooler marine air layer nearer the surface; and 2) radiation inversions – which are more localized and more typical of winter nights in interior parts of the Bay Area where air in contact with the ground cools more rapidly than the air layer above it.

1.2.2 Topography and Its Effect on Wind Speeds and Patterns

Low wind speed conditions limit horizontal air dispersion, and can result in the buildup of air pollutants. Poor air quality under low wind speed conditions can be especially pronounced in interior valleys, where the topography also contributes to the restriction of air movement and pollutant dispersion.

1.2.3 Solar Radiation and Its Impact on Photochemical Pollutants

The higher intensity and longer duration of solar radiation during the Bay Area's summer months provide ultraviolet light and warm temperatures that promote the formation of secondary photochemical pollutants (e.g., ozone (O_3)). Because sunlight intensity and summer temperatures are much higher in many of the Bay Area's inland valleys than near the coast, these inland areas are especially prone to photochemical air pollution.

As a consequence of all these factors, the parts of the Bay Area having the highest air pollution potential tend to be the inland areas, which experience higher temperatures in the summer and lower temperatures in the winter, and which are sheltered from the higher winds and more frequent fog episodes that affect the coastal areas. Also, because air pollutant levels depend on the amount of pollutants emitted locally or from upwind sources, ambient levels in inland areas are higher because they are subject to emissions transported by the prevailing winds from populous upwind areas.

Figure A4.3-PHYS-2
Chevron Refinery Modernization Project EIR
Gertrude and Pier Meteorological Station and Windroses (Indicating "Blowing From" Distribution)

1.2.4 Climate Subregion for Project Site

The Project site is located in the Northern Alameda and West Contra Costa County climatological subregion. In this subregion, marine air traveling through the Golden Gate, as well as across San Francisco, is a dominant weather factor. The Oakland-Berkeley Hills cause the westerly flow of air to split off to the north and south of Oakland, which causes diminished wind speeds.

The climate of the greater San Francisco Bay Area, including Richmond, is a Mediterranean-type climate characterized by warm, dry summers and mild, wet winters. The climate is determined largely by a high-pressure system often present over the eastern Pacific Ocean. In winter, the Pacific high-pressure system shifts southward, allowing storms to pass through the region. Richmond's maximum summer temperatures average in the low 70s and minimums average in the mid-50s. In winter, maximums are in the high 50s to low 60s and minimums are in the low to mid- 40s. The mean annual rainfall in Richmond, for the period between 1950 and 2010, is approximately 22 inches (WRCO, 2014).

Farther to the north, the Carquinez Strait is the only sea-level gap between San Francisco Bay and the Central Valley. The prevailing winds in the region are from the southwest; however, due to the heavy influence of topographic features in the project area, winds in Richmond are predominately from the south-southeast. During the summer and fall months, high pressure offshore coupled with low pressure in the Central Valley causes marine air to flow eastward through the Carquinez Strait.

The wind in the SFBAAB is strongest in the afternoon. Wind speeds may be strong locally in areas where air is channeled through a narrow opening, such as the Carquinez Strait. Afternoon wind speeds of 15 to 20 mph are common throughout the strait region. Annual average wind speeds are 8 mph in Martinez, and 9 to 10 mph further east.

The air flowing in from the coast to the Central Valley, called the sea breeze, begins developing at or near ground level along the coast in late morning or early afternoon. As the day progresses, the sea breeze layer deepens and increases in velocity while spreading inland. The depth of the sea breeze depends in large part upon the height and strength of the inversion. If the inversion is low and strong, and hence stable, the flow of the sea breeze will be inhibited and stagnant conditions are likely to result.

1.3 REGIONAL AIR QUALITY

Regional air quality is tracked for purposes of monitoring and either maintaining or achieving compliance with applicable air quality laws and regulations.

The legal framework for regulating air emissions is divided into two general categories of pollutants, and then further divided based on the nature of the activity or "source" of air pollution. The first category of pollutants is "criteria air pollutants" (CAPs), for which ambient air quality standards based on the protection of public health have been established under State and federal law. These criteria air pollutant standards, the types of sources that emit criteria air pollutants, and the region's status in complying with these standards, are described in *Section 1.3.1* below.

The second category of pollutants is "toxic air pollutants" (TACs), which comprise a wide variety of compounds determined to pose an actual or potential risk to public health, either by increasing cancer risks or increasing other health risks such as respiratory diseases like asthma. TACs have been of particular concern in Richmond, and have been evaluated in a variety of studies and are being addressed with various programs, as described below.

1.3.1 Criteria Air Pollutants

Federal and State air quality laws identify CAPs, including particulate matter (PM), ground-level ozone (O_3), carbon monoxide (CO), sulfur dioxide (SO_2), nitrogen oxides (NO_x), and lead (Pb). Additional details regarding the federal and State regulations pertaining to CAPs is in Appendix 4.3-REG.

1.3.1.1 Bay Area Criteria Air Pollutant Attainment Status

Attainment of ambient air quality standards is demonstrated with mandatory monitoring of regional air quality. BAAQMD operates a regional monitoring network that measures the ambient concentrations of six criteria air pollutants. The major pollutants of concern in the San Francisco Bay Area are O_3 , PM_{10} , $PM_{2.5}$, CO, NO_2 , and SO_2 . Within Contra Costa County, the BAAQMD operates or receives criteria air pollutant data from six monitoring stations in the local area. The monitoring stations along with the pollutants measured are described in Table A4.3-PHYS-1 below, and are shown in Figure A4.3-PHYS-3.

Based on this monitoring data, the SFBAAB is currently designated as an air quality attainment area under federal NAAQS standards for all pollutants except for O_3 (for which the region is designated as a marginal nonattainment area) and $PM_{2.5}$ (EPA, 2013a)¹ Under the California State standards, the region is a nonattainment area for O_3 , PM_{10} , and $PM_{2.5}$; and as an attainment or unclassified area for all other pollutants.

¹ SFBAAB is in non-attainment of the 24-hour $PM_{2.5}$ NAAQ; its status under the recently revised annual $PM_{2.5}$ standard is currently under review.

Source: BAAQMD, 2013c.

Of the six criteria air pollutants, O₃ is the only one that is not emitted directly to the air from emission sources. Instead, ground-level O₃ is formed from a chemical reaction between NO_x and VOCs, often referred to as precursors, in the presence of sunlight (EPA, 2013d). NO_x collectively refers to two oxides of nitrogen, namely NO and NO₂. VOCs refer to a general class of carbon-containing compounds that exhibit photochemical reactivity (i.e., can undergo a chemical reaction in air in the presence of sunlight). Different regulatory agencies (i.e., EPA, CARB and BAAQMD) have established different nomenclature and definitions of photochemically reactive organic compounds (i.e., VOCs, reactive organic compounds (ROGs), and precursor organic compounds (POCs)). However, these definitions are very similar and generally include the same organic compounds, with only minor differences in specific chemicals that are excluded (i.e., exhibit negligible photoreactivity, as determined by the specific regulatory agency). Although not defined by photoreactivity, total hydrocarbons (THC) is another term that is used by the United States Environmental Protection Agency (EPA) to encompass airborne organic compounds. Because THC, VOCs, ROGs, and POCs generally include the same organic compounds, in consultation with BAAQMD, it was determined that these were equivalent for the purposes of estimating and evaluating emissions for the purposes of this EIR. The definition of each of these terms and lists of specific organic compounds excluded from each category can be found on agency websites or in publicly available documents (CARB, 2009c; CFR 2010; BAAQMD, 1994).

As mentioned above, ambient concentrations of pollutants are determined by regional pollutant emissions, pollutant emissions in a given area, and wind

patterns and meteorological conditions for that area. As a result, ambient concentrations can vary among different locations within an area. The closest and most representative monitoring station locations to the Project site are Richmond and San Pablo. On January 1, 2013, the San Pablo Rumrill station began monitoring $PM_{2.5}$. Prior to this date, the nearest monitoring station in Contra Costa County that monitored $PM_{2.5}$ was located in Concord (2975 Treat Boulevard). Table A4.3-PHYS-2 shows a 5-year (2008-2012) summary of maximum concentration monitoring data collected from the Richmond (SO_2), San Pablo (O_3 , SO_2 , PM_{10} , $PM_{2.5}$, CO , and NO_2), and Concord ($PM_{2.5}$, CO , O_3 , and NO_2) stations, compared with Ambient Air Quality Standards (AAQS). The monitoring data show that O_3 , PM_{10} , and $PM_{2.5}$ periodically exceeded the AAQS during this period.

1.3.1.2 Criteria Pollutant Emissions—Contra Costa County

Table A4.3-PHYS-3 summarizes the emissions inventory for CAPs within Contra Costa County and within the entire SFBAAB for various source categories. According to Contra Costa County's emissions inventory, total mobile sources (on-road and off-road) are the largest contributor to the estimated annual average air pollutant levels of ROG, CO, and NO_x , accounting for approximately 42%, 78%, and 68%, respectively, of the total inventory as shown in Figure A4.3-PHYS-4.

Area-wide sources (e.g., solvent evaporation from equipment cleaning operations; on-site fuel combustion for space and water heating (e.g., hot water heaters); and landscape maintenance equipment such as lawnmowers and leaf blowers) account for approximately 76% of Contra Costa County's PM_{10} emissions and 57% of the County's $PM_{2.5}$ emissions (CARB, 2009a) as shown in Figure A4.3-PHYS-5.

Although mobile source emissions constitute the majority of the 2010 criteria air pollutant inventory both statewide and for Contra Costa County, emissions from this source category have decreased greatly since the 1970s due to more stringent federal and State emission controls on mobile sources and fuels. Examples of vehicle emissions standards include CARB's low-emission vehicle (LEV) standards (CARB, 2012), CARB's heavy-duty engine standards (CARB, 2013), and EPA's corporate average fuel economy (CAFE) standards for passenger cars and light duty trucks (EPA, 2013b). Examples of cleaner fuel standards include the elimination of lead from gasoline, and lowering of sulfur content in fuels (EPA, 2013c).

TABLE A4.3-PHYS-2 2008-2012 CRITERIA POLLUTANT AMBIENT AIR MONITORING DATA COLLECTED NEAR THE MODERNIZATION PROJECT

Pollutant	Standard	Value Federal Standard	Value State Standard					
				2008	2009	2010	2011	2012

	Annual Avg.(µg/m ³)	--	20	20.9	14.7	13.7	19.7	15.6

TABLE A4.3-PHYS-2 2008-2012 CRITERIA POLLUTANT AMBIENT AIR MONITORING DATA COLLECTED NEAR THE MODERNIZATION PROJECT

Pollutant	Standard	Value Federal Standard	Value State Standard					
				2008	2009	2010	2011	2012
Particulate Matter (PM _{2.5}) ^a (Concord)	Highest 24-Hour Avg. (µg/m ³)	35 ⁱ	--	60.3	39	36.4	47.5	32.2
	Days Over National Std.	--	--	3	1	1	2	0
		12 (primary)	12	9.3	8.4	7.1	7.8	6.5
	Annual Avg. (µg/m ³)	15 (secondary) ^j						

Notes: -- = indicates there was insufficient (or no) data available; ppm = parts per million; µg/m³ = microgram per cubic meter.

^a CARB-approved a new State 8-hour O₃ standard of 0.070 ppm on May 17, 2008, and approved new State 1-hour and annual NO₂ standards of 0.18 ppm and 0.03 ppm, respectively on February 22, 2007. The EPA approved a new federal 24-hour PM_{2.5} standard of 35 µg/m³ on September 21, 2006.

^b The San Pablo site was temporarily closed in March 2009 due to heavy damage from a building fire. No statistics are available for 2009 and therefore, data from the Concord site is reported here.

^c On June 2, 2010, the EPA established a new 1-hour SO₂ standard, effective August 23, 2010, and revoked both the existing 24-hr SO₂ standard and the annual primary SO₂ standard. Data shown is from the Richmond monitoring station.

^d Annual fourth-highest daily maximum 8-hour concentration, averaged over 3 years.

^e Not to be exceeded more than once per year.

^f 98th percentile of 1-hour daily maximum concentrations, averaged over 3 years.

^g 99th percentile of 1-hour daily maximum concentrations, averaged over 3 years.

^h Not to be exceeded more than once per year on average over 3 years.

ⁱ 98th percentile, averaged over 3 years.

^j Annual mean, averaged over 3 years.

Criteria pollutant emissions from mobile sources are projected to continue decreasing with vehicle fleet turnover to newer, cleaner models. However, while emissions from gasoline- and diesel-fueled mobile sources are showing a decreasing trend, a greater reduction in emissions from gasoline-fueled vehicles relative to diesel-fueled vehicles has increased the relative contribution of diesel sources to CAP from mobile sources (CARB, 2009). As a result, current regulatory development is focusing on reducing emissions from diesel vehicles (CARB, 2000).

Similarly, emissions from stationary sources such as Contra Costa's refineries and manufacturing facilities have decreased over time, both as a result of more stringent air pollution controls and as a result of the closure, downsizing or modification of these plants. For example, the BAAQMD prepared a historical inventory (BAAQMD, 2008) for ROG that shows a marked decrease in Facility emissions from 1990 projected through 2025, as shown in Figure A4.3-PHYS-6.

1.3.1.3 Criteria Pollutant Emissions Sources in Richmond and Surrounding Area

Local CAP sources include industrial activity in the vicinity of the Project site as well as emissions from the Port of Richmond, and vehicle emissions from nearby roadways, including Interstate 580 and Interstate 80. Table A4.3-PHYS-4 below summarizes estimated 2008 emissions from point sources at major facilities in Richmond. Table A4.3-PHYS-5 summarizes total CAP emissions in 2005 from the Port of Richmond.² These years represent information that is readily available to the public.

1.3.2 Toxic Air Contaminants

This section presents ambient air toxics monitoring data for the Project site and vicinity, as well as information regarding regional, local, and Facility emissions.

1.3.2.1 TAC Chemicals and Their Sources

Table A4.3-PHYS-6 presents source and health effect information for the ten TACs posing the greatest known health risks in California, based on ambient air quality data.

Ambient air monitoring data for TACs measured near the Facility is presented in Section 1.4.3 of this appendix.

1.3.2.2 TAC Emission Sources in Richmond and Surrounding Area

Major local TAC sources include industrial activity in the vicinity of the Project site, shipping and other maritime activities from the Port of Richmond and its tenants, and emissions from cars, trucks and trains using the area's highway, parkway, and rail transportation network. Like CAP emissions, TAC emissions result from the operation of factories and other "stationary" facilities, and from "mobile sources" such as passenger automobiles and light-duty trucks, other mobile equipment such as portable diesel generators, ships and harbor craft such as tugboats, cargo handling equipment, heavy duty trucks and construction equipment, and rail locomotives.

**TABLE A4.3-PHYS-6 SUMMARY OF SOURCES AND HEALTH EFFECTS OF TOP 10
CARCINOGENIC TACS IN CALIFORNIA**

TAC	Sources	Example Non-Cancer Chronic and Acute Effects
Acetaldehyde	Mobile engine exhaust Stationary source fuel combustion	Eye, skin, respiratory system irritation
Benzene	Fugitive emissions from gasoline Gasoline engine exhaust Crude oil and natural gas mining Petroleum refining Electricity generation Residential fuel combustion Natural petroleum seeps	Central nervous system effects
1,3-Butadiene	Mobile engine exhaust (incomplete combustion) Agricultural waste burning Residential wood burning Wildfires Oil/gas extraction Petroleum refining, synthetic material manufacturing	Neurological effects Eye, mucous membrane irritation
Carbon Tetrachloride	Chemical product manufacturing Petroleum refining	Respiratory tract irritation Central nervous system effects
Hexavalent Chromium	Industrial uses: chrome plating, chromic acid anodizing; glass furnace firebrick lining Gasoline motor vehicles	Renal toxicity Gastrointestinal hemorrhaging
p-Dichlorobenzene	Consumer products (insect repellants, air fresheners)	Eye, nose, throat irritation Liver, skin, central nervous system effects
Formaldehyde	Motor vehicle exhaust (complete combustion) Residential wood burning	Respiratory symptoms Eye, nose, throat irritation
Methylene Chloride	Plastic product and synthetics manufacturing Aircraft and parts manufacturing Paint stripping operations	Bone marrow, liver, Kidney effects
Perchloroethylene	Dry cleaning operations Aircraft part manufacturing Fabricated metal product manufacturing Consumer products (e.g. brake cleaners, tire sealants)	Liver toxicity Kidney dysfunction Neurological effects
Diesel Particulate Matter	Diesel fuel combustion	Reduced lung function

Note: All compounds in this list have been identified as carcinogens by the State of California.
Sources: CARB, 1998; CARB, 2009b.

Different TACs are emitted from different types of sources. A major TAC emitted by mobile sources and maritime sources is diesel particulate matter (DPM), which includes PM_{10} and $PM_{2.5}$. PM_{10} emissions from a portion of the Port of Richmond's maritime sources,³ for example, were quantified for year 2005 in the Port's 2010 emissions inventory prepared for the Bay Planning Coalition (BPC, 2010). The total particulate emissions for 2005 were estimated to be 6.5 tons from all maritime source categories at the Port. Of those, 92% of particulate emissions were attributed to ocean going vessels. Future growth at the Port, as well as CARB and EPA adopted regulations, will both increase and decrease DPM emissions in the future.

According to the 2008 through 2010 BAAQMD EIs, over 30 facilities in the City of Richmond emit TACs in addition to the Facility. Examples include, but are not limited to, ABS CBN International, AC Transit, Bayer HealthCare Pharmaceuticals, Inc., Bio-Rad Laboratories, BNSF Railway Company, BP West Coast Products, LLC, Catahoula Coffee Company, City of Richmond, ConocoPhillips, Contra Costa County, COR-O-VAN, DiCon Fiberoptics Inc., East Bay Municipal Utility District, Electro Forming Company, General Chemical West LLC, IMTT Richmond CA, JC Penny Company, Kaiser Permanente, Lal's Best Service Station, Levin Richmond Terminal Corporation, New NGC, Inc., Pacific Bell, Plains Products Terminals LLC, Point Richmond R & D Associates, Quality Dry Cleaners, Red Hanger Kleaners, Rolling Hills Memorial Park, Shell Oil Products US, Social Security Administration, State of California Department of Transportation, US Postal Service, United Parcel Service, Verizon Wireless, Wareham Property Group – EPA Lab, West Contra Costa County Landfill, and West County Wastewater District. Additional emissions inventory information for the Facility is available from its annual EPA Toxic Release Inventory (TRI) reports. Tables A4.3-PHYS-7 through A4.3-PHYS-9 summarize air toxics data from 2008 through 2010 from the BAAQMD Emissions Inventory for the Facility and for other available Richmond sources.

³ Privately owned terminals or non-maritime tenants are not included in the Port's 2005 emissions inventory and limited information is available to quantify these emissions. The Port tenants not explicitly captured in the inventory include ALOHA Storage, BP Arco, Conoco, GATX, National Gypsum, Sugar Dock, Brenntag Chemicals, BP Castrol, KKMI, Bay Marine Boatworks, Channel Lumber, IMTT, WAX, MANSON, Levin-Richmond Terminal, Atlantic Pipeline, SIMS Hugo Neu, and CAL Oils Refinery.

1.4 AIR QUALITY WITHIN THE CITY OF RICHMOND

1.4.1 Richmond and Neighborhoods Surrounding Facility

Figure A4.3-PHYS-7 shows the City of Richmond, including North Richmond (unincorporated Richmond) along with the location of the Modernization Project.

As shown in Figure A4.3-PHYS-8, the 2,153-acre Project site is located along the western boundary of the City of Richmond. The main portion of the Facility is bounded by the Chevron Richmond Marketing Fuels Terminal to the southeast and Chevron Energy Technology Company to the south.

The marine terminal and wharf (the “Long Wharf”) are located on the southern boundary of the Project site on the San Francisco Bay. The Long Wharf is over one mile long and receives and unloads crude oil and other raw materials shipped from worldwide locations, as well as loading refined products produced at the Facility for shipment elsewhere.

As shown in Figure A4.3-PHYS-9, a number of neighborhoods surround the Project site. The residential communities of Atchison Village, Santa Fe, and Iron Triangle are located southeast of the Project site, across Castro Street and Garrard Boulevard. The Shields-Reid community lies toward the northeast. Parchester Village is located northeast of the Project site and Point Richmond is located to the southwest. Point San Pablo Peninsula and the San Francisco Bay form the western border of the Project site and San Pablo Bay forms the northern boundary of the Facility property.

1.4.2 Sensitive Receptors within Refinery Vicinity Neighborhoods

For the purposes of air quality, public health, and noise analyses, sensitive receptors are generally defined as land uses with population concentrations that would be particularly susceptible to disturbance from dust, noise, vibration, air pollutant concentrations, or other disruptions associated with project construction and/or operation. These receptors generally include schools, day care centers, libraries, hospitals, residential care centers, parks, and churches. Some receptors are considered more sensitive than others to air pollutants. The reasons for greater than average sensitivity include pre-existing health problems, proximity to emissions sources, or duration of exposure to air pollutants. Schools, hospitals, and convalescent homes are considered to be relatively sensitive to poor air quality because children, elderly people, and the infirm are more susceptible to respiratory distress and other air quality-related health problems than is the general public. Residential areas are considered sensitive to poor air quality because people usually stay home for extended periods of time, with associated greater exposure to ambient air. Recreational uses are also considered sensitive due to the greater exposure to ambient air because

Figure A4.3-PHYS-8
Chevron Refinery Modernization Project EIR
Location of Project Site and Adjacent Land Use

vigorous exercise associated with recreation places a high demand on the human respiratory system.

Since the 1970s, Chevron has been relocating petroleum processing units northward, away from the community located near the southern and eastern boundaries of the Project site. This has created vacant land areas at the Facility's southern and eastern perimeter that serve as a physical separation or buffer, between Facility processing activities and adjacent off-site uses.

The five neighborhoods that have portions of the neighborhood within a one-mile radius of the Project site are Shields-Reid, Iron Triangle, Atchison Village, Point Richmond, and Santa Fe as shown in Figure A4.3-PHYS-9. The following is a listing of sensitive land uses within a mile of the Modernization Project's physical components (e.g., the new Hydrogen plant) as shown in Figure A4.3-PHYS-10:

- Atchison Park, the closest sensitive land use to the Modernization Project site, is approximately 5,200 feet or 1 mile from the closest physical modification proposed as part of the Modernization Project;
- Washington Park and Washington Elementary School are approximately 5,700 feet or 1.1 miles away;
- Richmond Municipal Natatorium is approximately 5,000 feet or 0.9-mile away; and
- Peres Elementary School is approximately 6,000 feet or 1.1 miles away.

Additional land use information is presented and discussed in more detail in *Section 4.10, Land Use Plans and Policies*.

1.4.3 Monitoring Richmond Air Quality

Air quality is monitored in Richmond by BAAQMD and Chevron for a variety of CAPs and TACs. Chevron monitors hydrogen sulfide (H_2S) and SO_2 at three locations in the vicinity of the Project site (Castro Street, Gertrude Street, and Golden Gate), and they are also starting a new community air monitoring program that will include $\text{PM}_{2.5}$, H_2S , ammonia (NH_3), and select metals, polycyclic aromatic hydrocarbons (PAHs), and other VOCs. BAAQMD monitors for H_2S at the Point Richmond station; H_2S , SO_2 , and a number of TACs at Richmond—7th Street station; and various criteria air pollutants (O_3 , PM_{10} , CO, NO_x , SO_2) and TACs at the nearby San Pablo Rumrill station. Further information on these monitoring networks is provided below.

1.4.3.1 Ambient TAC Monitoring in Richmond

H₂S concentrations are monitored by Chevron at a number of stations in and around the Project site. Table A4.3-PHYS-10 summarizes these data from Castro Street, Golden Gate, and Gertrude Street monitoring sites, for 2008 through 2010. The data shows two episodes where the hourly H₂S concentration exceeded the ambient air quality standard.

TABLE A4.3-PHYS-10 AIR QUALITY DATA SUMMARY (2008-2010) FROM FACILITY

Pollutant	Standard	Value	Site	2008	2009	2010
Hydrogen Sulfide	Highest 1-hour Avg (ppb)	30 ^a	Castro Street	10	8	5
			Gertrude Street	<u>66</u>	10	<u>111</u>
			Golden Gate	7	6	5

Notes: ppb = parts per billion. Values in **bold and underlined** are in excess of applicable standard.

^a State Standard. Generally, State standards are not to be exceeded.

Table A4.3-PHYS-11 summarizes H₂S concentrations from BAAQMD's Richmond 7th Street and Point Richmond stations for 2007 through 2009, the most recent complete years with quality controlled data available from BAAQMD's website. The data indicates there are no exceedances of the H₂S ambient air quality standard.

TABLE A4.3-PHYS-11 AIR QUALITY DATA SUMMARY (2007-2009) FROM RICHMOND 7TH STREET AND POINT RICHMOND STATIONS

M/P Xylene	0.330	1.433	0.534	2.318
O-Xylene	0.120	0.523	0.347	1.506

Notes: ppb = parts per billion; µg/m³ = micrograms per cubic meter.

^a Data is taken from the BAAQMD Richmond-7th Street and San Pablo-Rumrill monitoring stations for 2010.

^b Average of 27 samples at Richmond - 7th Street and 20 samples at San Pablo - Rumrill. Samples with concentrations below the method detection limit were assigned a value equal to one-half of the detection limit.

^c Acetone, Freon 113, and trichlorofluoromethane are not TACs.

^d Ethylene dibromide, ethylene dichloride, 1,3-butadiene, and vinyl chloride were not detected above the method detection limit in any of the samples at either station. In addition, at San Pablo - Rumrill only, methyl chloroform was not detected above the method detection limit in any of the samples.

1.4.3.2 Richmond Community Air Quality Monitoring Program

As part of a prior agreement with the City of Richmond, Chevron is funding and managing a new community air quality monitoring program. The program consists of air quality monitors in three nearby neighborhoods (Atchison Village, North Richmond and Point Richmond), as well as fenceline monitors at the Facility adjacent to those neighborhoods, as shown in Figure A4.3-PHYS-11. The monitors provide continuous and/or discrete data on $PM_{2.5}$, ozone, SO_2 , black carbon, H_2S , NH_3 , select metals, PAHs (monitored on an event-driven basis), and other VOCs. Real-time monitoring data is available to the public via the website, and monthly reports summarizing results for the three fenceline sites are compiled and made available on the website (Chevron, 2012).

The Richmond Community Air Monitoring Program was implemented in two phases. The first phase, which included a program website (www.fenceline.org/richmond) and real-time reporting of data from air monitoring equipment along the fenceline of the Project site, launched on April 5, 2013. The launch of the second phase, which included installation of equipment at community locations in the Atchison Village, North Richmond and Point Richmond neighborhoods, was staggered, starting in December 2013 and ending in January 2014 (City of Richmond, 2014).

Maximum detected concentrations measured since April 2013 by the fenceline monitoring equipment located adjacent to Point Richmond, Atchison Village, and North Richmond are summarized in Table A4.3-PHYS-13. As stated in the monthly reports available on the website, the concentrations of these compounds were lower than the toxicity standards established by the State of California. Note that the concentration of sulfur dioxide at Atchison Village on September 7, 2013, and October 16, 2013, was above the 1-hour short-term/acute exposure limit of 230 ppb used for the monitoring program; however, these concentrations only lasted for 5-minutes and did not last long enough for the 1-hour concentration to exceed the exposure limit, and the wind direction during these episodes was from the south or southeast, suggesting that they are not attributable to the Refinery (Argos Scientific, 2013).

Community monitoring data for Point Richmond, Atchison Village, and North Richmond are summarized in Table A4.3-PHYS-14. For all compounds except $PM_{2.5}$, the maximum detected concentrations for the month of available data (January 2014) are summarized in the table. For those compounds with exposure limits established for the community monitoring program, these maximum concentrations are all below the exposure limits. Note that this is a conservative comparison because the data is based on 5-minute averages but the exposure limits have averaging times of 1-hour or longer. For $PM_{2.5}$, the table includes a summary of the maximum daily and monthly average concentrations. As

Source: Argos Scientific, 2013.

indicated in the table, the maximum 24-hour average $PM_{2.5}$ concentration on January 24, 2014, is above the 24-hour NAAQS of $35 \mu\text{g}/\text{m}^3$ at the Atchison Village and North Richmond stations (36 and $38 \mu\text{g}/\text{m}^3$, respectively). However, this is not considered an exceedance of the NAAQS because the form of the 24-hour standard is the 98th percentile averaged over three years. While there is not enough data to make a direct comparison to the NAAQS, the 98th percentile of the data collected, which corresponds to the second highest 24-hour concentration at each station, is below the NAAQS of $35 \mu\text{g}/\text{m}^3$. Furthermore, a significant portion of the higher readings from January 24, 2014, occurred when the wind was blowing from the south or southeast, suggesting that they are not attributable to the Refinery. The form of the $PM_{2.5}$ annual primary ($12 \mu\text{g}/\text{m}^3$) and secondary ($15 \mu\text{g}/\text{m}^3$) standards is the annual mean, averaged over three years. Thus, a direct comparison to these annual standards is also not possible since only a single month of data has been reported. However, the monthly average concentrations at the Point Richmond and North Richmond stations are 12.04 and $14.78 \mu\text{g}/\text{m}^3$, respectively, which is slightly above the primary $PM_{2.5}$ standard concentration.

1.4.3.3 Chevron Ambient SO_2 Monitoring

SO_2 concentrations are monitored by Chevron at a number of stations at and around the Project site. Table A4.3-PHYS-15 summarizes these data from the Castro Street, Golden Gate, and Gertrude Street monitoring sites, for 2008 through 2012. The data shows several episodes where the SO_2 concentration exceeds the applicable ambient air quality standards. The Refinery received a notice of violation (NOV A51291A) for exceeding BAAQMD's Regulation 9 Rule 1 SO_2 concentration limit on December 21, 2010. Although it appears that SO_2 concentrations measured at the facility monitors exceeded BAAQMD's Regulation 9 Rule 1 SO_2 concentration limit during 2011 and 2012, there is no record of NOVs for elevated SO_2 concentration during these years.

1.4.3.4 Other Emissions Monitoring and Reporting

Air emissions of CAPs and TACs from the Facility and other facilities in Richmond are monitored, recorded and reported to federal, State and local regulatory authorities as part of a number of different regulatory programs. These include BAAQMD (e.g., BAAQMD EI, Regulation 9 Rule 10 Reporting, RLOP permit reporting) and EPA air permitting programs (e.g., Title V permitting, Prevention of Significant Deterioration permitting and New Source Review), and other emissions tracking and reporting programs (e.g., CARB Air Toxics "Hot Spots" (AB2588) Program, EPA Toxic Release Inventory (TRI), EPA National Emission Inventory (NEI)). The measurement and reporting frequency of emissions monitoring data depends on the specific program, and publicly available summaries of emissions monitoring data are typically available as hourly-average

TABLE A4.3-PHYS-14 SUMMARY OF CONCENTRATIONS (PPB) MEASURED BY THE COMMUNITY MONITORING EQUIPMENT LOCATED POINT RICHMOND, ATCHISON VILLAGE, AND NORTH RICHMOND

values or as annual totals by pollutant. The purpose of many of these programs is to provide regulators, as well as the general public, a way of continuously monitoring overall air emissions in a locality or region. These air emissions monitoring and reporting programs also provide specific information regarding the contributions to air pollution on a local and regional basis, and assist in informing policy decisions to improve or maintain air quality.

1.4.4 Evaluations of Richmond Air Quality

Air quality has been a longstanding concern for Richmond. There have been several studies of past conditions, and there are ongoing monitoring activities

and studies underway, of Richmond's air quality. Two major studies are described below.

1.4.4.1 TAC Study Comparing Richmond and Bolinas

A community-based participatory research collaboration involving the Silent Spring Institute, Communities for a Better Environment, and faculty from Brown and the University of California at Berkeley, completed a 2009 exposure study comparing indoor and outdoor air samples from 40 homes in communities adjacent to the Project site to samples from 10 homes in the rural, coastal community of Bolinas, California in Marin County (Green-Brody, 2009). These 24-hour integrated samples were analyzed for pollutants including particulates, metals, PAHs, polychlorinated biphenyls (PCBs), ammonia, sulfates, pesticides, flame retardants, phthalates, and phenols. Unlike Richmond, Bolinas has no industrial facilities, has no freeways, has no Port, is not adjacent to urbanized areas with industrial facilities or freeways, and has an isolated population base of approximately 1,620, relative to Richmond's population of 210,000, located adjacent to populated communities. The study also used other available data from California Environmental Protection Agency (Cal/EPA) State ambient air quality monitors. The following results were reported in the study:

- More air pollutants and higher outdoor concentrations of air emissions were detected in urbanized Richmond than in rural Bolinas.
- Nickel and vanadium, which are generally associated with refineries, other industrialized operations, and shipping were detected in Richmond at some of the highest concentrations when compared to a distribution of monitoring data from Cal/EPA State ambient air quality monitors.
- Despite high traffic in Richmond, outdoor concentrations of certain particulates and traffic-related pollutants were in the lower half of the distribution of Cal/EPA's Statewide monitoring data.
- There is a correlation between outdoor and indoor concentrations that suggests that outdoor pollutants likely penetrate into homes.

As noted in the journal article, limitations of the study include the small sample size in Bolinas, and the lack of multi-season samples or direct Facility emissions samples to compare to household contaminant profiles.

The BAAQMD initiated the Community Air Risk Evaluation (CARE) program in 2004 to evaluate and reduce health risks associated with exposures to outdoor TACs in the Bay Area. The program examines TAC emissions from point sources, area sources and mobile sources near sensitive populations to help focus air quality mitigation strategies. The main objectives of the program are to:

- Characterize and evaluate potential cancer and non-cancer health risks associated with exposure to TACs from both stationary and mobile sources throughout the Bay Area.
- Assess potential exposures to sensitive receptors including children, senior citizens, and people with respiratory illnesses.
- Identify significant sources of TAC emissions and prioritize use of resources to reduce TACs in the most highly impacted areas (i.e., priority communities).
- Develop and implement mitigation measures - such as grants, guidelines, or regulations - to achieve cleaner air for the public and the environment, focusing initially on priority communities.

The BAAQMD used the information gathered during the initial CARE process to designate communities with higher relative TAC exposure levels (CARE Communities).

The Modernization Project is located within the Richmond/San Pablo CARE Community, which is one of six impacted communities identified under the CARE program, as described below.

The CARE program methodology also evaluated risk reductions projected to occur in the near term based on the implementation of air quality improvement mandates already required and in the process of being implemented, such as cleaner fuels for cars and trucks, and more stringent emission standards designed to reduce diesel and other pollutants. As shown in Figures A4.3-PHYS-12 and A4.3-PHYS-13, the estimated cancer risk in 2015 for locations in the vicinity of the Modernization Project ranges from 100 to 300 in a million (BAAQMD, 2012). These risks may not accurately represent localized risk for a couple of reasons. First, the risks are presented in broad ranges (i.e., increments of 100 in a million), so the estimated risks can fall anywhere within the specified range. Second, the risks were estimated for large areas (i.e., using grid cells with one kilometer by one kilometer spacing) that are assumed to have uniform risk across an entire grid cell, but localized variations in risk within each grid cell may exist.

1.4.4.1.1 CARE Program Phases I and II Inventories

During Phases I and II of the CARE program, the BAAQMD developed a preliminary Bay Area-wide TAC emissions inventory (based on county-level area source and non-road mobile source emissions, point source emissions inventory, and gridded on-road mobile emissions inventory); compiled demographic and health-statistics data; and conducted regional computer modeling of selected TAC species to identify communities that are disproportionately impacted from high concentrations of TACs. As shown in Figure A4.3-PHYS-14 for 2005, five TACs (i.e., diesel particulate matter (DPM), 1,3-butadiene, benzene, hexavalent

Bay Area-wide Contributions to Airborne Toxic Cancer Risk
by Pollutant, Based on 2005 Emissions Inventory

chromium, and formaldehyde) were estimated to be responsible for about 97% of the Bay Area's cumulative cancer risk, and DPM alone for about 86% of this cancer risk. Major sources of DPM include on-road mobile sources and construction equipment, as shown in Figure A4.3-PHYS-15. The CARE TAC evaluation methodology evaluated dozens of individual TAC constituents, including TACs from mobile sources (i.e., trucks and cars), stationary sources (i.e., refineries and factories) and area sources (i.e., water heaters). Of the TACs evaluated, BAAQMD concluded that the five most relevant to purposes of understanding ambient TAC-related health risks are DPM, 1,3-butadiene, benzene, formaldehyde, and acetaldehyde.

1.4.4.1.2 Impacted Communities

The District used data on TAC emissions and risk to identify impacted communities. The impacted communities are areas where the District focuses policies and programs to reduce TAC emissions and exposures. The emissions and concentrations data were combined with locations of sensitive populations and income levels to identify communities with relatively higher impacts from air quality than other Bay Area communities.

The CARE program identified six impacted communities in the Bay Area including Concord, eastern San Francisco, western Alameda County, Redwood City/East Palo Alto, Richmond/San Pablo, and San Jose (see Figure A4.3-PHYS-16).

1.4.5 Other Policy Considerations

In addition to the evaluations of air quality in Richmond as described above, the California Environmental Protection Agency (Cal/EPA) has also used a health screening tool to evaluate the impact of various environmental indicators in Richmond, as further discussed below.

1.4.5.1 Cal EnviroScreen

The Cal/EPA California Communities Environmental Health Screening Tool, Version 1.1 (CalEnviroScreen 1.1) (OEHHA, 2013) provides a State-wide assessment methodology designed to help characterize the combined relative impacts of multiple pollutants and stressors on a community. CalEnviroScreen's methodology is based on the evaluation of a series of 17 indicators⁴ of the environment, including air pollution as well as other forms of pollution such as contaminated soils and water, socioeconomic factors, and the presence of sensitive populations. The CalEnviroScreen rankings are specifically intended to be used to help direct resources, and focused attention, on areas of California

⁴ These indicators are: O₃, PM_{2.5}, DPM, pesticides, toxic release inventory, traffic, cleanup sites, groundwater threats, hazardous waste sites, impaired water bodies, solid waste sites, age, asthma, low birth weight, education, linguistic isolation and poverty.

 Care Impacted Communities

that have higher levels of hazardous materials-related activities and/or higher sensitivities to such activities.

Using zip codes as the geographic unit of analysis, CalEnviroScreen uses a variety of data bases that measure different "indicators" or factors relevant to hazardous materials usage and emissions, and sensitivity to hazards, including US census information, to create a total numerical "score" for each zip code. Higher scores indicate higher levels of hazardous materials-related activity and/or higher sensitivity to such hazardous materials-related activities. CalEnviroScreen also includes a comparative ranking system that allows the relative scores for each indicator, and the aggregate score of all indicators, to be ranked by zip code across the State.

There are seven zip codes in the city of Richmond (94801, 94802, 94804, 94805, 94807, 94808, and 94850) and one zip code partially in the city of Richmond (94806); three of these zip codes are for post office boxes only (94802, 94807, and 94808), and 94850 has no population.

For populated zip codes in the vicinity of the Project site (94801, 94804, 94805 and 94806 (see Figure A4.3-PHYS-17), the CalEnviroScreen results (Table A4.3-PHYS-16) indicate that 94801 is in the top 96 to 100% (most impacted) zip codes within the State,⁵ while zip code 94804 is in the top 86 to 90% of zip codes in the State, zip code 94805 is in the 50 to 55% group, and zip code 94806 is in the 76-80th percentile.

In the Cal EnviroScreen calculations of indicator percentiles for each zip code, the higher the ranking, the greater the impact. As shown in Table A4.3-PHYS-16, all four zip codes with a non-zero population scored above the 90th percentile for asthma; zip codes 94801, 94804, and 94806 exceeded 94th percentile for zip codes with legacy toxic contamination conditions requiring cleanup. Zip codes 94801 and 94804 exceeded 90% for groundwater threat percentiles and impaired water bodies percentiles, with zip code 94806 having only modestly lower percentiles of 82% and 87%, respectively. For these indicators, there is little differentiation among these specific zip codes, suggesting that populations in these zip codes may experience similar impacts and vulnerabilities due to those

⁵ CalEnviroScreen was developed in part to address the Cap and Trade program established for Greenhouse Gas emissions under AB 32. Specifically, Senate Bill (SB) 535 requires that 25% of California's cap and trade auction proceeds (Assembly Bill 32) be spent on programs that benefit disadvantaged communities. SB 535 also directed Cal/EPA to identify disadvantaged communities in order to support the allocation of auction fund proceeds. Accordingly, the Office of Environmental Health Hazard Assessment (OEHHA) used CalEnviroScreen results to identify the top 10% of impacted zip codes as 'disadvantaged' for the purpose of identifying zip codes such as 94801 that qualify for Cap and Trade auction fund proceeds.

TABLE A4.3-PHYS-16 CALENVIROSCREEN PERCENTILES FOR RICHMOND, CA**POPULATION BURDEN INDICATORS**

ZIP Code	O ₃ Percentile	PM _{2.5} Percentile	Diesel PM Percentile	Pesticides Percentile	TRI Percentile	Traffic Percentile	Cleanup Sites Percentile	Groundwater Threats Percentile	Haz. Waste Percentile	Imp. Water Bodies Percentile	Solid Waste Percentile
94801	0%	32%	63%	16%	99%	59%	100%	96%	100%	91%	99%
94804	0%	33%	81%	0%	74%	81%	99%	94%	89%	93%	0%
94805	0%	35%	75%	0%	0%	90%	69%	30%	33%	28%	0%
94806	0%	36%	66%	11%	0%	86%	94%	82%	74%	87%	0%
94850	0%	34%	90%	0%	0%	99%	31%	0%	5%	0%	0%

POPULATION CHARACTERISTICS INDICATORS

ZIP Code	Total Population	Age Percentile	Asthma Percentile	Low Birth Weight Percentile	Education Percentile	Linguistic Isolation Percentile	Poverty Percentile
94801	29,395	44%	98%	69%	86%	84%	83%
94804	38,559	42%	98%	83%	68%	68%	65%
94805	13,648	35%	93%	25%	53%	62%	44%
94806	59,861	35%	93%	60%	79%	76%	61%
94850	0	N/A	N/A	N/A	N/A	N/A	N/A

FINAL CALENVIROSCREEN SCORE

ZIP Code	CalEnviroScreen Percentile Range ¹
94801	96-100%
94804	86-90%
94805	51-55%
94806	76-80%
94850	NA

factors. Linguistic isolation percentiles (an indicator measuring the population with limited proficiency in English) ranged from 62% (94805) to 68% (94804) to 76% (94806) to 84% (94801). Educational attainment scores were similar to linguistic isolation percentiles, and showed the same trend among zip codes, indicating that the greatest impacts from these indicators are associated with populations in zip code 94801. Zip code 94801 also received the highest percentile ranking for hazardous wastes (100%), compared to 89% (94804), 74% (94806), and 33% (94805).

DPM concentrations ranked in the 81st percentile for zip code 94804, but were somewhat lower for 94801 (63%), 94806 (66%), and 94805 (75%) as shown in Table A4.3-PHYS-16. Although zip code 94850 has no population, it was scored on pollution burden indicators and ranked in the 90th percentile for DPM. Traffic scores placed zip codes 94804, 94805, 94806, and 94850 above the 80th percentile, with zip code 94801 associated with a percentile of 59%. The Toxic Release Inventory (TRI) percentiles indicate that zip code 94801 is relatively impacted by facility releases (99th percentile), with zip code 94804 also ranked high at 74%. There were no TRI releases in zip codes 94805, 94806, and 94850. Zip code 94801 placed in the 99th percentile for solid waste sites, while all of the other zip codes received scores of zero for this indicator. Zip code 94801 also had the highest percentile for poverty (83%), with the other three populated zip code percentiles ranging between 44% and 65%. The highest percentile for low birth weight was calculated for zip code 94804 (83%), followed by zip code 94801 (69%), 94806 (60%), and 94805 (25%).

All populated zip codes scored similarly for PM_{2.5} levels (32% to 36%) and for age (35% to 44%); O₃ concentration data were not available for any of the zip codes. Pesticide usage was not a significant contributor to overall score, with zip codes 94801 and 94806 in approximately the 16th and 11th percentiles, respectively, while zip codes 94804, 94805, and 94850 received scores of zero for the pesticide indicator, in that none of the pesticides evaluated by CalEnviroScreen were used in these zip codes.

Although Richmond zip codes 94801, 94804, 94805, 94806, and 94850 are in direct proximity to one another and share similar environmental and population burdens for some indicators, the relatively high percentile rankings for multiple indicators within zip code 94801 and the relatively low percentile rankings for 94806 and 94805 in certain indicators were important determinants of the final scores they received. The total score for zip code 94804 was intermediate to the other three populated zip codes, and included contributions from a number of high-percentile indicators.

APPENDIX 4.3 - REG

REG: Air Quality Regulations

APPENDIX 4.3

REG: AIR QUALITY REGULATIONS

Air quality within the San Francisco Bay Area Air Basin (SFBAAB) is addressed through the efforts of various federal, state, regional, and local government agencies. These agencies work individually and jointly to improve air quality through legislation, regulations, planning, policymaking, education, and programs. This appendix discusses air regulatory context for the Modernization Project.

1.1 REGULATION OF CRITERIA AIR POLLUTANTS

1.1.1 Federal and State Ambient Air Quality Standards

The Federal Clean Air Act (FCAA) required the United States Environmental Protection Agency (EPA) to establish National Ambient Air Quality Standards (NAAQS), which set limits on pollutants in ambient air to protect public health and welfare. In response, the EPA established both primary and secondary standards for six pollutants (called “criteria” pollutants), which come from numerous and diverse sources. These six criteria pollutants are: ozone (O_3); carbon monoxide (CO); nitrogen dioxide (NO_2); sulfur dioxide (SO_2); particulate matter (PM)—including respirable particulates (less than 10 microns in diameter [PM_{10}]) and fine particulates (less than 2.5 microns in diameter [$PM_{2.5}$]); and lead. Primary standards are designed to protect human health including the health of “sensitive” populations, such as asthmatics, children and the elderly. Secondary standards are designed to protect property and public welfare, including protection against visibility impairment and damage to animals, crops, vegetation, and buildings, from air pollutants in the atmosphere. Table A4.3-REG-1, includes a summary of the sources and health effects of the various criteria pollutants.

The FCAA allows states to adopt ambient air quality standards and other regulations, provided that they are at least as stringent as federal standards. The California Air Resource Board (CARB) has established the more stringent California Ambient Air Quality Standards (CAAQS) for the six criteria pollutants through the California Clean Air Act of 1988 (CCAA), and also has established CAAQS for additional pollutants, including sulfates, hydrogen sulfide (H_2S), vinyl chloride and visibility-reducing particles.

TABLE A4.3-REG-1 CRITERIA POLLUTANTS, THEIR PRECURSORS, SOURCES, AND RELATED HEALTH EFFECTS

Pollutant	Sources and Health Effects
PM _{2.5} and PM ₁₀	Respirable and fine particulates (PM₁₀ and PM_{2.5}, respectively) pose a serious health hazard, individually or in combination with other pollutants. More than half of the smallest particles inhaled get deposited in the lungs and can cause permanent lung damage. Respirable particles have been found to increase morbidity and mortality via the following adverse health effects: decreased lung function, aggravated asthma, exacerbation of lung and heart disease symptoms, chronic bronchitis and irregular heartbeats. In addition, respirable particles can act as a carrier of absorbed toxic substances.^[b] Particulate matter in the atmosphere results from many kinds of dust- and fume-producing industrial and agricultural operations, fuel combustion, and atmospheric photochemical reactions. Some sources of PM, such as demolition and construction activities, are local in nature, while others, such as vehicular traffic, have a more regional effect. Very small particles of certain substances (e.g., sulfates and nitrates) can cause lung damage directly, or can contain adsorbed gases (e.g., chlorides or ammonium) that may be injurious to health. Particulates also can damage materials and reduce visibility. In addition to directly emitted particulates, NO_x and SO_x are precursors of PM₁₀ and PM_{2.5}.
Ozone (O ₃)	Ozone is not emitted directly into the atmosphere, but is a secondary air pollutant produced in the atmosphere through a complex series of photochemical reactions involving VOCs and nitrogen oxides (NO_x). Because VOC and NO_x in the atmosphere can cause O₃, these chemicals are known as precursor compounds for O₃. Significant O₃ production generally requires O₃ precursors to be present in a stable atmosphere with strong sunlight for approximately 3 hours. Ozone concentrations tend to be higher in the late spring, summer, and fall, when the long sunny days combine with regional subsidence inversions to create conditions favorable to the formation and accumulation of secondary photochemical compounds, like O₃. Elevated O₃ concentrations have been shown to induce airway irritation, cause airway inflammation, induce wheezing and difficulty breathing, aggravate pre-existing respiratory conditions such as asthma, and can lead to permanent lung damage after repeated exposure to elevated concentrations.
Carbon Monoxide (CO)	Carbon monoxide is a colorless and odorless gas that is known to cause aggravation of various aspects of coronary heart disease, dizziness, fatigue, impairment to central nervous system functions, and possible increased risk to fetuses. CO is a non-reactive pollutant that is a product of incomplete combustion, and is mostly associated with motor vehicle traffic. High CO concentrations develop primarily during winter when periods of light winds combine with the formation of ground level temperature inversions (typically from the evening through early morning). These conditions result in reduced dispersion of

TABLE A4.3-REG-1 CRITERIA POLLUTANTS, THEIR PRECURSORS, SOURCES, AND RELATED HEALTH EFFECTS

Pollutant	Sources and Health Effects
	vehicle emissions. Motor vehicles also exhibit increased CO emission rates in cold weather.
Sulfur Dioxide (SO ₂)	Sulfur dioxide is known to cause irritation in the respiratory tract, shortness of breath, and can injure lung tissue when combined with fine PM. SO ₂ is a combustion product of sulfur or sulfur-containing fuels such as coal, which are restricted in the Bay Area. SO ₂ is also a precursor to the formation of atmospheric sulfate and PM (PM ₁₀ and PM _{2.5}), and contributes to potential atmospheric sulfuric acid formation that could become acid rain downwind.
Lead	Lead has a range of adverse neurotoxin health effects, and was formerly widely released into the atmosphere primarily via leaded gasoline. Other sources of lead include lead smelters, and lead battery manufacturing. The phase-out of leaded gasoline in California resulted in decreasing levels of atmospheric lead.
Nitrogen Dioxide (NO ₂)	Nitrogen dioxide is a reddish-brown gas that is a by-product of combustion processes. Automobiles and industrial operations are the main sources of NO ₂ . NO ₂ may be visible as a coloring component of a brown cloud on high pollution days, especially in conjunction with high O ₃ levels. Long-term exposure to NO ₂ has the potential to decrease lung function and worsen chronic respiratory symptoms and diseases in sensitive populations. It has also been associated with cardiopulmonary mortality and emergency room asthma visits.

NO_x = oxides of nitrogen

SO_x = oxides of sulfur

VOC = volatile organic compound

Sources: EPA, 2012a, 2012c, 2013c.

CARB and EPA designate an area's attainment status with respect to the CAAQS and NAAQS, respectively. The purpose of these designations is to identify areas with air quality problems and thereby initiate planning efforts for improvement. The three basic designation categories are "nonattainment," "attainment," and "unclassified." The "unclassified" designation is used in an area that cannot be classified on the basis of available information as meeting or not meeting the standards.

Table A4.3-REG-2 includes the NAAQS and CAAQS currently in effect for each of the criteria pollutants, and the most recent attainment designations with respect to the SFBAAB.

TABLE A4.3-REG-2 AMBIENT AIR QUALITY STANDARDS

Pollutant	Avg. Period	California Standard	Federal Standard	SFBAAB Attainment Status Under California Standard	SFBAAB Attainment Status Under Federal Standard
Ozone (O ₃)	1-hour	0.09 ppm (180 µg/m ³)	Revoked	Serious Nonattainment	--
	8-hour ^a	0.07 ppm (137 µg/m ³)	0.075 ppm (147 µg/m ³)	Nonattainment	Marginal Nonattainment
Respirable Particulate Matter (PM ₁₀)	24-hour	50 µg/m ³	150 µg/m ³	Nonattainment	Unclassified
	Annual	20 µg/m ³	Revoked	Nonattainment	--
Fine Particulate Matter (PM _{2.5})	24-hour	--	35 µg/m ³	--	Nonattainment
	Annual ^b	12 µg/m ³	12 µg/m ³	Nonattainment	Attainment/ Under review
Carbon Monoxide (CO)	1-hour	20 ppm (23 mg/m ³)	35 ppm (40 mg/m ³)	Attainment	Attainment
	8-hour	9 ppm (10 mg/m ³)	9 ppm (10 mg/m ³)	Attainment	Attainment
Nitrogen Dioxide (NO ₂)	1-hour ^c	0.18 ppm (339 µg/m ³)	0.100 ppm (188 µg/m ³)	Attainment	Unclassified
	Annual	0.030 ppm (57 µg/m ³)	0.053 ppm (100 µg/m ³)	--	Attainment
Lead ^d	Rolling 3-Mo. Avg.	--	0.15 µg/m ³	--	Attainment
	30-Day Avg.	1.5 µg/m ³	--	Attainment	--
Sulfur Dioxide (SO ₂) ^e	1-hour	0.25 ppm (655 µg/m ³)	0.075 ppm (196 µg/m ³)	Attainment	Attainment
	3-hour ^f	--	0.5 ppm (1300 µg/m ³)	--	Attainment
	24-hour	0.04 ppm (105 µg/m ³)	--	Attainment	--
Hydrogen Sulfide (H ₂ S)	1-hour	0.03 ppm (42 µg/m ³)	--	Unclassified	--
Vinyl Chloride	24-hour	0.01 ppm (26 µg/m ³)	--	--	--
Sulfates	24-hour	25 µg/m ³	--	Attainment	--
Visibility-Reducing Particles	8-hour	Extinction coefficient of 0.23 per kilometer (visibility of less than 10 miles due to particles when relative humidity is less than 70%)	--	Unclassified	--

TABLE A4.3-REG-2 AMBIENT AIR QUALITY STANDARDS

Pollutant	Avg. Period	California Standard	Federal Standard	SFBAAB Attainment Status Under California Standard	SFBAAB Attainment Status Under Federal Standard
------------------	------------------------	--------------------------------	-----------------------------	---	--

Notes: ppm = parts per million; $\mu\text{g}/\text{m}^3$ = micrograms per square meter

^a On March 27, 2008, the 8-hour national O_3 standard was lowered from 0.08 ppm to 0.075 ppm. This standard is expressed as the annual fourth-highest daily maximum 8-hour concentration, averaged over 3 years.

^b The EPA revised the primary standard on December 14, 2012 from 15 $\mu\text{g}/\text{m}^3$ to 12 $\mu\text{g}/\text{m}^3$. States are required to submit their area designation recommendations under the revised standard by December 13, 2013. The secondary standard is 15 $\mu\text{g}/\text{m}^3$.

^c The 1-hour national standard for NO_2 was promulgated on February 9, 2010. To attain the 1-hour national standard, the 3-year average of the annual 98th percentile of the 1-hour daily maximum concentrations at each site must not exceed 100 ppb.

^d The national standard for lead was revised on October 15, 2008 to a rolling 3-month average. The 1978 lead standard (1.5 $\mu\text{g}/\text{m}^3$ as a quarterly average) remains in effect until 1 year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978 standard, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.

^e On June 2, 2010, a new 1-hour SO_2 standard was established and the existing 24-hour and annual primary standards were revoked. To attain the 1-hour national standard, the 3-year average of the annual 99th percentile of the 1-hour daily maximum concentrations at each site must not exceed 75 ppb. The 1971 SO_2 national standards (24-hour and annual) remain in effect until 1 year after an area is designated for the 2010 standard, except that in areas designated nonattainment for the 1971 standards, the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standards are approved.

^f This is a secondary standard.

The following sections summarize criteria pollutant-related plans, programs and regulations at the federal, state, regional and local levels that are relevant to the Facility.

1.1.2 Air Quality Plans

The FCAA and the CCAA require State Implementation Plans (SIPs) to be developed for areas designated as nonattainment (with the exception of areas designated as nonattainment for the State PM_{10} standard). The SIP must integrate federal, state, and local actions and regulations to identify specific control measures to reduce pollution to attain the NAAQS by the required compliance date. Plans are also required under federal law for areas designated as “maintenance” for national standards. The FCAA Amendments of 1990 added requirements for states with nonattainment areas to revise their SIPs to incorporate additional control measures to reduce air pollution. Air quality plans usually define control strategies to reduce air pollutant emissions from industrial facilities, commercial processes, motor vehicles, and other sources. Control

strategies are typically implemented through a combination of regulations adopted and enforced by the air district, grant and incentive programs, public education and outreach, and partnerships with other agencies and stakeholders.

The responsibility for developing plans and programs for each air basin has been delegated to the regional air district responsible for attaining and maintaining air quality standards in that air basin. CARB is the agency responsible for developing the SIP in California. The SIP is periodically modified to reflect the latest emissions inventories, planning documents, and rules and regulations of the air basins as reported by their regional air districts. The EPA has responsibility to review all state SIPs to determine conformation to the mandates of the FCAA Amendments, and to determine if implementation will achieve air quality goals. If the EPA determines a SIP to be inadequate, a Federal Implementation Plan (FIP) may be prepared for the nonattainment area that imposes additional control measures. Failure to submit an approvable SIP or to implement the plan within the mandated timeframe may result in sanctions being applied to transportation funding and stationary air pollution sources in the air basin.

The Modernization Project is within the SFBAAB, which is an area designated as nonattainment for not meeting NAAQS for certain pollutants regulated under the FCAA (O_3 , $PM_{2.5}$), as shown in Table A4.3-REG-2. Currently, there are four plans for the Bay Area:

- **Ozone Attainment Plan for the 1-Hour National Ozone Standard** (ABAG, 2001), which was developed to meet federal O_3 air quality planning requirements. Bay Air Quality Management District (BAAQMD) prepares O_3 attainment plans for the national O_3 standard, and clean air plans for the California standard, both in coordination with the Metropolitan Transportation Commission (MTC) and Association of Bay Area Governments (ABAG). The most recent O_3 attainment plan was submitted in 2001 and was approved by the EPA in 2004. The EPA determined that the SFBAAB had attained the national 1-hour O_3 standard; this standard has since been replaced by an 8-hour standard.
- **Carbon Monoxide Maintenance Plan** (BAAQMD, 1994), which was developed to ensure continued attainment of the national CO standard;
- **Bay Area 2005 Ozone Strategy** (BAAQMD, 2006a), adopted by the BAAQMD Board of Directors on January 4, 2006, which reviews the region's progress over the years in reducing O_3 levels; describes current conditions and charts a course for future actions to further reduce O_3 and O_3 precursor levels in the Bay Area and achieve compliance with the State 1-hour O_3 standard. The control strategy includes stationary source measures, mobile source measures and transportation control measures.

- **Clean Air Plan** (BAAQMD, 2010), which serves to update the 2005 Bay Area Ozone Strategy and also provides an integrated, multi-pollutant strategy to improve air quality, protect public health, and protect the climate.

With respect to applicable air quality plans, BAAQMD prepared the 2010 Clean Air Plan to address nonattainment of the national 8-hour O₃ standard and nonattainment of the CAAQS in the SFBAAB. The purpose of the 2010 Clean Air Plan is to:

- Update the Bay Area 2005 Ozone Strategy in accordance with the requirements of the CCAA to implement all feasible measures to reduce O₃;
- Consider the impacts of O₃ control measures on PM, air toxics, and greenhouse gases in a single, integrated plan;
- Review progress in improving air quality in recent years; and
- Establish emission control measures to be adopted or implemented in the 2009-2012 timeframe.

The updated clean air plan describes current conditions, reviews the progress in reducing SFBAAB O₃ levels to attain State 1-hour and 8-hour O₃ standards, and describes how the proposed control strategy for the SFBAAB will fulfill the CCAA planning requirements for the State 1-hour O₃ standard and mitigation requirements for transport of O₃ and O₃ precursors to neighboring air basins. The 2010 Clean Air Plan also considers the impacts of O₃ control measures on PM, air toxics, and greenhouse gases in a single, integrated plan. The control strategies include stationary source control measures to be implemented through BAAQMD regulations; mobile source control measures to be implemented through incentive programs and other activities; and transportation control measures to be implemented through programs in cooperation with the MTC, local governments, transit agencies, and others.

1.1.3 Federal Stationary Source Regulations

1.1.3.1 Title V Operating Permit (40 CFR Part 70)

Title V of the 1990 FCAA Amendments requires all major sources and some minor sources of air pollution to obtain an operating permit. A Title V permit grants a source permission to operate, and includes all air pollution requirements that apply to the source, including emissions limits and monitoring, record keeping, and reporting requirements. It also requires that the source report its compliance status with respect to permit conditions to the permitting authority. The applicability threshold for a major source is dependent on whether the area is in attainment or nonattainment, and is based on the potential to emit criteria

pollutants. Title V permits are typically issued by state or local agencies, although a small number of permits are issued by the EPA (EPA, 2013f).

Title V permits in the Bay Area are issued by the BAAQMD. In the Bay Area, Title V requirements are implemented by Regulation 2 Rule 6 of the BAAQMD *Rules and Regulations*. In the BAAQMD, any source that emits or has the potential to emit 100 tons per year (tons/yr) or more of any CAP is a major source and must obtain a Title V operating permit. The Facility is a major facility as defined by BAAQMD Regulation 2-6-212, and hence is subject to the Operating Permit requirements of Title V of the FCAA, and BAAQMD Regulation 2, Rule 6 (Major Facility Review).

Chevron's current Title V permit was issued on August 11, 2011, by the BAAQMD and will expire on August 10, 2016. The permit regulates 297 sources including combustion sources (e.g., furnaces, heaters, boilers, and engines), tanks, cooling towers, flares, and Facility-specific process sources such as crude unit, rheniformers, hydrotreaters, and miscellaneous permitted sources such as H₂S plants, bio-reactor, and loading facilities. The permit also incorporates various abatement devices including precipitators, baghouses, scrubbers, tail gas units, carbon absorbers, thermal oxidizers, and diesel particulate filters. The permit also lists various exempt sources. The current Title V permit will be updated by BAAQMD to reflect Modernization Project changes upon completion of Modernization Project construction and when BAAQMD issues to Chevron the permits to operate for the Modernization Project.

1.1.3.2 Prevention of Significant Deterioration (40 CFR Part 52)

The Prevention of Significant Deterioration (PSD) regulations were first promulgated by the EPA (40 CFR 52) to prevent air quality degradation in those areas where CAP concentrations are below the ambient standards (i.e., attainment areas). The PSD permitting program sets forth preconstruction review requirements for major stationary sources (new construction or major modifications) to ensure that air quality in clean air areas does not significantly deteriorate, while maintaining a margin for future industrial growth. Currently, the federal PSD regulations are administered by BAAQMD on behalf of the EPA, as BAAQMD does not yet have its own, EPA-approved PSD program.¹ PSD requirements will apply if increased emissions resulting from proposed modifications to a major source due to the Modernization Project exceed PSD

¹ BAAQMD has approved a proposed PSD rule (embodied in revisions to BAAQMD Regulation 2, Rule 2) and submitted it to EPA for approval, which is still pending. If and when BAAQMD's PSD rule is approved by EPA, BAAQMD will assume responsibility for PSD implementation and enforcement for EPA. The BAAQMD PSD rule is more stringent than the EPA PSD rule currently in effect by applying an "actual to potential" emissions calculation test instead of the current "actual to projected actual" test applied under the federal PSD program (BAAQMD, 2012b).

threshold levels. PSD requires the installation of Best Available Control Technology (BACT), an air quality analysis, impacts modeling and analysis, and public involvement (EPA, 2013d).

Exceedance of a PSD trigger level requires a demonstration by dispersion modeling that the emissions will not interfere with the attainment or maintenance of any NAAQS at the point of maximum impact, and will not cause an exceedance of a PSD increment. The Facility is a “major source” for the purposes of the federal PSD program. The Modernization Project, however, does not amount to a “major modification” and thus will not be subject to PSD requirements. This is further discussed in the Engineering Evaluation, which is *Appendix 4.3-EE* to this report.

1.1.3.3 New Source Performance Standards (40 CFR Part 60)

The EPA promulgated New Source Performance Standards (NSPS) for major and minor sources on a category-by-category basis. NSPS are national emission standards that are progressively tightened over time to achieve a steady rate of air quality improvement without unreasonable economic disruption. The NSPS imposes uniform requirements on new and modified sources based on the best demonstrated technology (BDT). BDT refers to the best system of continuous emissions reduction that has been demonstrated to work in a given industry, considering economic costs and other factors, such as energy use. In other words, any new source of air pollution must install the best control system currently in use within that industry (EPA, 2013a). The NSPS program is implemented by the BAAQMD. Table A4.3-REG-3 summarizes NSPS regulations that are cited in the Facility’s current Title V Operating Permit.

The Modernization Project will include sources that will be subject to NSPS subpart Ja (Standards of Performance for Petroleum Refineries for Which Construction, Reconstruction, or Modification Commenced After May 14, 2007), which applies to fluid catalytic cracking units, fluid coking units, delayed coking units, flares, fuel gas combustion devices (e.g., process heaters), and sulfur recovery plants. The rule specifies PM, NO_x, SO₂, and CO emission limitations and monitoring requirements for fluid catalytic cracking units and fluid coking units; SO₂ emission limitations and annual maintenance hour limitation for sulfur recovery plants; SO₂ emission and fuel gas H₂S content limitations for fuel gas combustion devices; and NO_x emission limits for process heaters. This rule also describes testing, monitoring, recordkeeping and reporting requirements.

1.1.3.4 Flares

The EPA signed final amendments to NSPS subpart Ja for flares and process heaters at petroleum refineries on June 1, 2012 (NSPS Ja Final) (EPA, 2012d). The

TABLE A4.3-REG-3 SUMMARY OF SUBPARTS UNDER 40 CFR PART 60 (NEW SOURCE PERFORMANCE STANDARDS) LISTED IN THE FACILITY'S TITLE V OPERATING PERMIT

40 CFR Part 60		
Subpart	Description	Summary
A	General Provisions	Generally applies to any stationary source for which construction or modification is commenced after applicable date. Includes requirements for performance testing; compliance with standards and maintenance; monitoring; modification and reconstruction; general control device and work practice; and notification, recordkeeping and reporting.
D	Standards of Performance for Fossil-Fuel-Fired Steam Generators	Generally applies to steam generating units for which construction, modification, or reconstruction commenced after 1971, and that has a maximum design heat input capacity greater than or equal to 250 million British Thermal Units (MMBTU)/hour. Includes NO _x , SO ₂ and PM emission limits. Also covers compliance and performance test methods and procedures; emission monitoring requirements; and reporting and recordkeeping requirements.
Db	Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units	Generally applies to steam generating units for which construction, modification, or reconstruction commenced after June 1984, and that have a maximum design heat input capacity greater than 100 MMBTU/hour. Includes NO _x , SO ₂ and PM emission limits. Also covers compliance and performance test methods and procedures; emission monitoring requirements; and reporting and recordkeeping requirements.
Dc	Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units	Generally applies to steam generating units for which construction, modification, or reconstruction commenced after June 9, 1989, and that has a maximum design heat input capacity greater than or equal to 10 MMBTU/hour but less than or equal to 100 MMBTU/hour. Includes SO ₂ and PM emission limits, but does not have limits for units fired exclusively on natural gas. Also covers compliance and performance test methods and procedures for SO ₂ and PM; emission monitoring requirements for SO ₂ and PM; and reporting and recordkeeping requirements.
J ^a	Standards of Performance for Petroleum Refineries	Generally applies to fluid catalytic cracking unit catalyst regenerators or fuel gas combustion devices flares, and Claus sulfur recovery plant, which commenced construction, reconstruction, or modification between 1973 and 2008 (depending on the source type). The standard sets emission limits of PM, opacity, CO, SO ₂ ; and limits the fuel gas H ₂ S content to 0.1 grains per dry standard cubic foot (gr/dscf). The facility also needs to comply with monitoring,

TABLE A4.3-REG-3 SUMMARY OF SUBPARTS UNDER 40 CFR PART 60 (NEW SOURCE PERFORMANCE STANDARDS) LISTED IN THE FACILITY'S TITLE V OPERATING PERMIT

40 CFR Part 60		
Subpart	Description	Summary
		recordkeeping and reporting requirements for opacity, CO, SO ₂ emissions, fuel gas H ₂ S content, coke burn-off rate and/or hours of operation.
Kb	Standards of Performance for Volatile Organic Liquid Storage Vessels	Generally applies to tanks greater than 75 m ³ built after 1984; certain exceptions apply. Sets standards regarding tank roofs, venting systems and control devices; provides direction on testing, recordkeeping, monitoring and reporting.
GG	Standards of Performance for Stationary Gas Turbines	Set standards for NO _x and SO ₂ on stationary gas turbines, as well as monitoring requirements.
VV ^b	Standards of Performance for Equipment Leaks of VOC in the Synthetic Organic Chemicals Manufacturing Industry for which Construction, Reconstruction, or Modification Commenced After January 5, 1981, and on or Before November 7, 2006	Sets design, operational and monitoring requirements for equipment used in VOC service (i.e., contains or contacts process fluid with 10% VOC by weight); also describes recordkeeping and reporting requirements.
GGG ^c	Standards of Performance for Equipment Leaks of VOC in Petroleum Refineries for which Construction, Reconstruction, or Modification Commenced After 1/4/83 and on or Before 11/7/06	Sets design, operational and monitoring requirements for equipment used in VOC service (i.e., contains or contacts process fluid with 10% VOC by weight); also describes recordkeeping and reporting requirements.
QQQ	Standards of Performance for VOC Emission From Petroleum Refinery Wastewater Systems	Specifies design, operational and monitoring requirements for wastewater-related equipment such as oil-water separators; drain systems; closed vent systems; control devices; also describes monitoring, recordkeeping, and reporting requirements.

Notes: MMBTU = million British Thermal Units; VOC = volatile organic compound; gr/dscf = grains per dry standard cubic foot

^a Subpart Ja generally applies to fluid catalytic cracking units, fluid coking units, delayed coking units, fuel gas combustion devices (including process heaters), flares and sulfur recovery plants at petroleum refineries for which construction, reconstruction, or modification commenced after 2007 (depending on the source type). Additional information is provided later in this section.

^b Subpart VVa applies to construction, reconstruction, or modification after November 7, 2006.

^c Subpart GGGa applies to construction, reconstruction, or modification after November 7, 2006.

final rule re-defines a flare as a separate affected facility rather than a type of fuel gas combustion device, and requires refineries to: (1) develop and implement a flare management plan; (2) conduct root cause analyses and take corrective action when waste gas sent to the flare exceeds a certain flow rate above the baseline flow or contains sulfur that will emit more than 500 pounds of SO₂ in a 24-hour period; (3) optimize management of the fuel gas by limiting the short-term concentration of H₂S during normal operating conditions; and (4) equip flares with flow and sulfur monitors.

Facilities located in the BAAQMD may elect to comply with both BAAQMD Regulation 12, Rule 11 (Flare Monitoring and Petroleum Refineries) and BAAQMD Regulation 12, Rule 12 (Flares at Petroleum Refineries) as an alternative to complying with the requirements of subpart Ja.

1.1.3.5 Protection of Stratospheric Ozone: Recycling and Emissions Reduction (40 CFR Part 82 Subpart F)

The purpose of these regulations is to reduce emissions of class I and class II refrigerants and their substitutes to the lowest achievable level by restricting sales and maximizing the recapture and recycling during service, maintenance, repair, and disposal of appliances. It specifies certification of technicians, required practices, standards for recycling and recovery equipment, and reporting and recordkeeping requirements.

1.1.4 Federal Mobile and Marine Source Regulations

The EPA has adopted an array of regulations aimed to reduce emissions from mobile and marine sources. Generally, control of emissions from diesel fuel combustion focuses on two strategies: setting limits on the amount of sulfur in diesel fuel, and setting source-specific emissions standards, which are typically met through emissions control technologies. Both types of strategies are demonstrated in the regulations summarized below.

1.1.4.1 Diesel Fuel and Engine Regulations (Highway and Non-Road (Including Marine)) [40 CFR Parts 69, 80 and 86]

1.1.4.1.1 Mobile Sources

1.1.4.1.1.1 Emission Standards for Heavy-Duty Engines and Vehicles

To reduce emissions from on-road, heavy-duty diesel trucks, EPA established a series of increasingly strict emission standards for new engines, starting in 1988. The EPA promulgated the final and cleanest standards with the 2001 Heavy-Duty Engine and Vehicle Standards and Highway Diesel Fuel Sulfur Control Requirements Rule, more commonly known as the 2007 Highway Rule (EPA, 2001), which integrated engine and fuel controls as a system to gain the greatest emission reductions. This rule established a PM emission standard of 0.01 gram

per horsepower-hour (g/hp-hr) for new vehicles beginning with model year 2007. NO_x and non-methane hydrocarbon standards of 0.20 g/hp-hr and 0.14 g/hp-hr, respectively, were phased in together between 2007 and 2010 on a percent-of-sales basis: 50% from 2007 to 2009 and 100% in 2010.

1.1.4.1.1.2 Highway Diesel Fuel Sulfur Requirements

The 2007 Highway Rule also required refineries to begin producing highway diesel fuel that met a maximum sulfur standard of 15 parts per million (ppm), known as ultra-low sulfur diesel (ULSD), by June 2006. All 2007 and later model year diesel-fueled vehicles must be refueled with ULSD. By integrating fuel sulfur standards and advanced pollution control technologies, the 2007 Highway Rule reduces diesel particulate matter (DPM) and NO_x exhaust emissions of heavy-duty engines by more than 90% as compared to previous engine models. In addition, ULSD also enables emissions reductions from other diesel-powered highway vehicles, including cars, sport utility vehicles, and light-duty trucks.

1.1.4.1.1.3 Emission Standards for Non-road Diesel Engines

To reduce emissions from non-road diesel equipment, EPA established a series of emission standards, called Tiers, for new non-road diesel engines culminating in the 2004 Non-road Tier 4 Final Rule (EPA, 1998, 2004). The Tier standards apply to non-road engines such as engines found in construction, general industrial, and terminal equipment; but do not apply to locomotives or marine engines rated above 37 kilowatt (kW) (50 horsepower [HP]). The Tier 1, Tier 2, Tier 3, and Tier 4 standards require compliance with progressively more stringent emission limits. Tier 1 standards were phased in from 1996 to 2000 (year of manufacture), depending on the engine HP category. Tier 2 standards were phased in from 2001 to 2006 and the Tier 3 standards were phased in from 2006 to 2008. To meet these standards, engine manufacturers will produce new engines with advanced emissions control technologies similar to those already expected for on-road heavy-duty diesel vehicles. The Non-road Tier 4 standards are currently being phased in starting with smaller engines in 2008 until all but the very largest diesel engines meet NO_x and PM standards in 2015.

1.1.4.1.1.4 Non-road Diesel Fuel Sulfur Requirements

The Non-road Tier 4 Final Rule for non-road diesel engines also established fuel sulfur limits in order to integrate engine and fuel controls as a system to gain the greatest emission reductions. The rule required low sulfur (500 ppm) diesel fuel to be phased in starting in 2007, and requires ULSD (15 ppm) to be phased in over 2010-2012 for non-road, locomotive, and marine engines (though only for diesel fuel, not for marine residual fuel, which is more typically used by very large ocean-going vessels). The Tier 4 engine and fuel standards complement the 2007 Highway Rule for on-road heavy-duty engine and vehicles discussed above

by requiring 90% reductions in DPM and NO_x exhaust as compared to previous engine models. For the Modernization Project, this rule affects line-haul locomotives; the California Diesel Fuel Regulations (described below) generally pre-empt this federal rule for other sources such as intrastate locomotives, construction equipment, terminal equipment, and harbor craft engines. Under the Non-road Tier 4 Final Rule, the diesel fuel used by line-haul locomotives was limited to 500 ppm starting June 1, 2007, and was further limited to 15 ppm starting January 1, 2012.

1.1.4.1.2 Marine Engines

EPA has promulgated several emission standards and fuel sulfur requirements for marine diesel engines, which apply depending on the size of the engine.

1.1.4.1.2.1 Small Marine Diesel Engines (Less than 37 kW)

Marine diesel engines less than 37 kW (50 HP) are regulated under the Non-road Diesel Rule (EPA, 2004), described above. For marine diesel engines less than 37 kW or 50 HP, this rule established Tier emission standards and limits diesel fuel sulfur content to 500 ppm starting June 1, 2007 and 15 ppm starting January 1, 2012.

1.1.4.1.2.2 Marine Diesel Engines Less than 30 Liters per Cylinder Displacement

In 2008, EPA finalized a rule that established emission standards for marine diesel engines less than 30 liters per cylinder displacement (EPA, 2008a). The rule covers all types of marine diesel engines of this size, including commercial, recreational, propulsion, and auxiliary engines. Examples include propulsion engines on recreational vessels, small fishing boats, towboats, and tugboats, and auxiliary engines ranging from small to large generator sets on ocean-going vessels. The rule establishes a three part program: (1) establishes emission standards for existing remanufactured engines above 600 kW (800 HP); (2) establishes Tier 3 emission standards for newly built marine engines to be phased in starting in 2009, based on currently available technology; and (3) establishes Tier 4 standards for newly built marine engines to be phased in starting in 2014, based on high-efficiency catalytic after-treatment technology. When fully implemented, the rule will reduce PM emissions from these engines by as much as 90% and NO_x emissions by as much as 80%.

1.1.4.1.2.3 Category 3 Marine Diesel Engines (Greater than 30 Liters per Cylinder Displacement)

Category 3 marine diesel engines have per-cylinder displacement at or above 30 liters per cylinder, and are primarily used for propulsion power on ocean-going vessels such as container ships, tankers, bulk carriers, and cruise ships. Category 3 marine diesel engines typically range in size from 2,500 to 70,000

kW (3,000 to 100,000 HP). In an April 2010 rule (EPA, 2010), EPA adopted emission standards for Category 3 engines installed on U.S. vessels, and diesel fuel sulfur standards for marine diesel fuels produced and distributed in the United States. The rule establishes Tier 2 standards starting in 2011 and Tier 3 standards that will apply starting in 2016. It also adopts a regulatory program for implementing Annex VI to the International Maritime Organization (IMO) International Convention for the Prevention of Pollution from Ships in the United States (MARPOL), including engine and fuel sulfur limits, and extends the emission control area (ECA) engine and fuel standards to U.S. internal waters. These MARPOL requirements are described below. Finally, the rule also allows for the U.S. production and sale of diesel fuel with up to 1,000 ppm sulfur, which can be used in Category 3 marine vessels. All other marine engines are limited to diesel fuel with a maximum sulfur content of 15 ppm, as per the Nonroad Diesel Rule, described above.

1.1.4.1.2.4 Marine Diesel Engines Greater than 130 kW (175 HP) and 30 Liters per Cylinder Displacement, and All Marine Diesel and Residual Fuels

International emission standards apply to new marine diesel engines larger than 130 kW (175 HP) and all marine diesel and residual fuels. For vessels flagged and registered in the United States, EPA's diesel engine and fuel standards will apply for all but the very largest new marine diesel engines (those above 30 liters per cylinder displacement). For those engines above 30 liters per cylinder and for residual fuels, including new marine diesel engines and fuels on foreign vessels that operate in the U.S.'s coasts and ports, the IMO MARPOL Annex VI standards apply. EPA implemented the MARPOL Annex VI standards in Title 40 Code of Federal Regulations Part 1043 (EPA, 2008b).

The IMO is the United Nations agency concerned with maritime safety, security, and pollution prevention. The IMO first adopted MARPOL Annex VI standards in 1997, which included limits on NO_x and SO_x emissions from ship exhausts, and prohibited deliberate emissions of O₃ depleting substances. In October 2008, the IMO adopted amendments to MARPOL Annex VI that placed new NO_x limits on engines, and a global limit on marine fuel sulfur content (including both diesel and residual fuel) of 35,000 ppm (3.5%) by 2012, reduced to 5,000 ppm (0.5%) sulfur by 2020 (or 2025, pending a technical review in 2018).

The amendments also established additional, more stringent emission requirements for ships that operate in designated coastal areas where air quality problems are acute, called ECAs). Under the new geographic standards, ships operating in designated ECAs will be required to use engines that meet the most advanced technology-forcing standards for NO_x emissions beginning in 2016, use fuel with a sulfur content not exceeding 10,000 ppm (1%) in the first phase of the program (2010), and use 1,000 ppm (0.1%) in the second phase of the

program (2015). On March 26, 2010 the IMO amended MARPOL Annex VI by designating specific portions of U.S. waters as ECAs, including the Pacific coast. For this area, the effective date of the first-phase fuel sulfur standard was 2012, and the second phase begins in 2015. Beginning in 2016, NO_x after-treatment requirements become applicable.

Progressive reductions in NO_x emissions from marine diesel engines installed on ships are also included, with a "Tier II" emission limit for engines installed on or after 1 January 2011; then with a more stringent "Tier III" emission limit for engines installed on or after 1 January 2016 operating in ECAs (the IMO Tier III standards are only applicable within ECAs). Marine diesel engines installed on or after 1 January 1990 but prior to 1 January 2000 are required to comply with "Tier I" emission limits, if an approved method for that engine has been certified by EPA.

1.1.5 State Programs and Regulations

CARB is the State agency responsible for coordination and oversight of state and local air pollution control programs in California and for implementing the CCAA. The CCAA, which was adopted in 1988, requires that all air districts in the State endeavor to achieve and maintain the CAAQS by the earliest practical date (Cal H&S Code Section 39000 et seq.). The CCAA specifies that districts should focus particular attention on reducing the emissions from transportation and area-wide emission sources, and provides districts with the authority to regulate indirect sources.

CARB is primarily responsible for developing and implementing air pollution control plans to achieve and maintain the NAAQS and produces a major part of the SIP. In addition, the CARB is primarily responsible for statewide pollution sources, although local air districts are still relied upon to provide additional strategies for sources under their jurisdiction.

1.1.5.1 Control of Particulate Matter—Senate Bill 656

CARB and regional air districts are responsible for implementing the provisions of Senate Bill (SB) 656 (Sher, 2003), which seeks to reduce PM₁₀ and PM_{2.5} air pollution. As a first step, CARB developed and approved a list of readily available, feasible, and cost-effective control measures based on existing California rules, regulations, and programs for stationary, area-wide, and mobile sources. The regional air districts then identified schedules for implementation of selected measures, prioritizing measures based on the extent of the PM problem in their jurisdiction, as well as based on the cost-effectiveness of the selected measures. Currently, air districts are working on evaluating and adopting rules in their specific implementation schedules. These schedules, along with CARB's other programs, are designed to continue progressing towards reducing the public's

exposure to PM and towards attaining the state and federal ambient air quality standards (CARB, 2004e).

1.1.5.2 CARB Air Toxic Control Measure for Stationary Compression Ignition Engines (17 CCR 93115)

The CARB Air Toxic Control Measure (ATCM) for Stationary Compression Ignition Engines was adopted in 2004 and amended in May 2011 (CARB, 2011b), with the goal of reducing criteria pollutant and DPM emissions from diesel-fueled stationary compression ignition engines. The ATCM outlines emission standards, fuel use requirements, and operational hour limitations for prime and emergency back-up engines. The 2011 amendments harmonized many of the ATCM requirements with the 2006 EPA Standards of Performance for Stationary Compression-Ignition Internal Combustion Engines (EPA, 2006) (NSPS Subpart IIII); however, some ATCM emission standards and other requirements are more stringent than the NSPS.

1.1.5.3 Regulation of Other Stationary Sources

Other diesel-fueled stationary combustion sources such as boilers and turbines are regulated in the state of California through regional air district rules. For the Modernization Project, the regulating air district is the BAAQMD. The BAAQMD rules applicable to stationary diesel combustion sources are discussed in this section.

1.1.5.4 CARB Airborne Toxic Control Measure for Portable Engines Rated at 50 HP and Greater

ARB promulgated an ATCM for portable diesel-fueled engines in 2004 and amended it in 2011 (CARB, 2011a) to reduce PM emissions from diesel-fueled engines with a rated brake HP of 50 and greater. If subject to the ATCM, portable engines must use CARB diesel fuel, a verified alternative diesel fuel that has been verified appropriately, or CARB diesel fuel utilizing verified fuel additives.

1.1.5.5 Statewide Portable Equipment Registration Program

Under CARB's Statewide Portable Equipment Registration Program (CARB, 2011h), owners/operators of portable engines greater than 50 brake HP such as back-up diesel generators and other specific equipment can register their equipment for operation throughout California. This voluntary program avoids the need of obtaining permits from the local air districts. The requirements of the program, which were most recently revised in February 2011, include meeting eligibility criteria, recordkeeping and reporting, and inspections.

1.1.5.6 State Mobile and Marine Source Regulations

Similar to the EPA, California has adopted an array of regulations aimed to reduce emissions from mobile and marine fuel combustion sources, including both fuel and source-specific emissions standards such as emissions control technologies. State regulations demonstrating both types of emissions reduction strategies are detailed below.

1.1.5.6.1 Diesel Fuel Regulations (Title 13, CCR, Section 2281, 2282, 2284, 2299; Title 17, CCR, Section 93117)

In 1988, CARB proposed an initial diesel fuel regulation limiting the sulfur content and aromatic hydrocarbon content of diesel fuel for motor vehicles. In 1998, CARB identified particulate emissions from diesel-fueled engines (DPM) as a TAC. CARB developed the Risk Reduction Plan to Reduce Particulate Matter Emissions from Diesel-Fueled Engines and Vehicles (CARB, 2000a) and the Risk Management Guidance for the Permitting of New Stationary Diesel-Fueled Engines (CARB, 2000b) and approved these documents in September 2000. These documents proposed to reduce diesel particulate emissions and the associated health risk by 75% in 2010 and by 85% in 2020, and to require the use of state-of-the-art catalyzed diesel particulate filters and ultra-low sulfur diesel fuel. The 1988 initial diesel fuel regulation was subsequently amended, and additional regulations were passed. The Risk Management Guidance for the Permitting of New Stationary Diesel-Fueled Engines was also amended (CARB, 2002a). The current standards for diesel fuel in California are listed below (CARB, 2013c, 2013f).

- A. Sulfur Content of Diesel Fuel (CARB, 2004d) – This standard prohibited the sale of vehicular diesel fuel with a sulfur content exceeding 500 ppm by weight after 1993. Starting in 2006, the sulfur limit was reduced to 15 ppm to be phased in over June through September 2006.
- B. Aromatic Hydrocarbon Content of Diesel Fuel (CARB, 2004b) – This standard prohibited the sale or supply of any diesel fuel after 1993 if the aromatic hydrocarbon content exceeds 10% by volume.
- C. Lubricity of Diesel Fuel (CARB, 2004c) – This standard prohibits the sale or supply of any diesel fuel unless the fuel meets minimum lubricity level.
- D. Harborcraft and Locomotives (CARB, 2005c) – Starting in 2007, this amendment extended the definition (and associated requirements) of vehicular diesel fuel to diesel fuel used in harborcraft such as towboats and tugboats and intrastate locomotives (i.e., 90% of annual fuel consumption, hours of operation, or miles traveled occur within California, which would typically include short haul, switch, industrial, port, and terminal operations).

- E. Ocean-Going Vessels (CARB, 2011e) – This regulation, adopted in 2008 and amended in 2011, established low sulfur fuel requirements for marine engines, auxiliary engines, and auxiliary boilers within 24 nautical miles of the California coastline. Starting in 2009, the regulation required the use of marine gas oil (MGO) with a maximum sulfur content of 1.5% or marine diesel oil (MDO) with a maximum sulfur content of 0.5%. By August 1, 2012 the maximum allowable sulfur content of MGO and MDO are 1.0 and 0.5%, respectively. By January 1, 2014, the maximum allowable sulfur content of MGO and MDO is 0.1%.

These California regulations establish the same fuel sulfur content limits as the federal diesel fuel regulations described in Section 1.1.4.1 above (1,000 ppm [0.1%]) for ocean-going vessels fueled by MGO or MDO, and 15 ppm (0.0015%) for all other diesel-fueled engines); however, the California fuel regulations accelerate the effective dates of the requirements for non-highway applications within California by 3 to 5 years.

1.1.5.6.2 Heavy Duty Diesel Truck Idling Regulation

CARB adopted the in-use heavy duty diesel truck idling ATCM in July 2004. As a follow-up to this ATCM, CARB approved the Heavy Duty Diesel Truck Idling regulation (CARB, 2004a, 2013d), which affected heavy-duty diesel trucks starting in February 2005. The regulation requires in-state and out-of-state registered sleeper berth equipped trucks to shut down their engines if idling for longer than 5 minutes at a time, except in the case of queuing (if the queue is located beyond 100 feet from any homes or schools). The regulation also establishes engine performance standards, which require non-programmable engine shutdown systems on heavy-duty diesel engines of model year 2008 and later; these systems shut down the engine after 5 minutes of idling or, alternatively, the engines can optionally meet strict emission standards for NO_x emissions during idling. Trucks with engines of model year 2006 or older may use any California or federally certified diesel-fueled auxiliary power system or fuel-fired heaters.

1.1.5.6.3 CARB Statewide Truck and Bus Regulation

CARB adopted the Statewide Truck and Bus Regulation in December 2008 and amended it in December 2011 (CARB, 2011c, 2014c). The regulation requires heavy-duty vehicles to be retrofitted with PM filters beginning January 1, 2012, and requires older vehicles to be replaced starting January 1, 2015. By January 1, 2023, nearly all trucks and buses must have 2010 model year engines or equivalent.

1.1.5.6.4 California Exhaust Emission Standards and Test Procedures

CARB has adopted emission standards for on-road heavy-duty engines and vehicles and test procedures and amended it in December 2012 (CARB, 2002b, 2012a).

CARB Off-Road Emissions Regulation for Compression-Ignition Engines and Equipment

Engines designated as nonroad engines by EPA are known as off-road engines in California state regulations implemented by CARB. Similar to the EPA Nonroad Diesel Rule, the Off-Road Emissions Regulation for New Compression-Ignition Engines and Equipment (CARB, 2004f, 2012c) applies to diesel engines such as those found in construction, general industrial, and terminal equipment, but not locomotives or marine engines rated above 37 kW (50 horsepower (HP)). Initially adopted in 2000 and amended in 2004, the regulation establishes Tier emission standards, test procedures, and warranty and certification requirements. For some model years and engine size, the CARB Tier emission standards are more stringent than the EPA standards.

1.1.5.6.5 CARB In-Use Off-Road Diesel Vehicle Regulation

In July 2007 CARB adopted the In-Use Off-Road Diesel Vehicle Regulation and amended it in December 2011 (CARB, 2011g, 2013e). The regulation requires owners of off-road mobile equipment powered by diesel engines 25 HP or larger to meet the fleet average or BACT requirements for NO_x and PM emissions by January 1 of each year. The regulation also establishes idling restrictions, limitations on buying and selling older off-road diesel vehicles (Tier 0), reporting requirements, and retrofit and replacement requirements. The requirements and compliance dates vary by fleet size, with performance requirements for large fleets beginning in 2014, medium fleets in 2017, and small fleets in 2019. Requirements regarding idling, disclosure, reporting, and labeling took effect in 2008 and 2009. The Diesel Off-road On-line Reporting System (CARB, 2012b) is an online tool designed to help fleet owners report their off-road diesel vehicle inventories and actions taken to reduce vehicle emissions to the CARB, as required by the In-Use Off-Road Diesel Vehicle Regulation.

1.1.5.6.6 CARB Surplus Off-Road Opt-In for NO_x

The Surplus Off-Road Opt-In for NO_x (SOON) Program was originally adopted with the statewide Regulation for In-Use Off-Road Diesel Vehicles (Off-Road Rule) in 2008 and would apply to districts whose governing board elected to opt into the provision of the program. The SOON Program requires applicable fleets to meet a more stringent fleet-average NO_x target than the statewide Off-Road Rule on a compliance schedule. BAAQMD has elected not to opt into the SOON Program.

1.1.5.6.7 CARB/Railroad Statewide Agreement

In 2005, CARB entered into a voluntary agreement with Union Pacific Railroad and BNSF Railway (CARB, 2005b, 2011f). This agreement committed Union Pacific Railroad and BNSF Railway to reducing locomotive and associated DPM emissions near rail yards through 2008. In addition, the agreement included provisions for CARB to perform health risk assessments (HRA) at 17 rail yards in California, with the results of each used to develop long-term mitigation measures for each rail yard. In addition to this agreement, CARB is developing regulations to address on- and off-road vehicles at rail yards. The CARB/Railroad agreement and associated regulations is one of the efforts to achieve the goals of CARB's Diesel Risk Reduction Plan (described above). When fully implemented, the agreement is expected to achieve a 20% reduction in locomotive DPM emissions near rail yards.

1.1.5.6.8 Requirements for Intrastate Locomotive Fuel Use

In November 2004, the CARB approved a regulation (CARB, 2004g) placing standards on the fuel used in intrastate locomotives. Beginning January 1, 2007, diesel fuel sold for use in intrastate diesel-electric locomotives operating in California must meet the specifications of CARB diesel fuel, as discussed above in Section 1.1.4.6.1 (Diesel Fuel Regulations). Intrastate (diesel-electric) locomotives are defined as those locomotives that operate and fuel primarily (at or greater than 90% of annual fuel consumption, mileage, and/or hours of operation) within the boundaries of the state of California.

1.1.5.6.9 CARB Ocean-Going Vessels Fuel Sulfur and Other Operational Requirements

In July 2008, CARB approved a regulation (CARB, 2011e, 2013f) placing standards on the fuel sulfur content and operations of ocean-going vessels operating within 24 nautical miles of the California coast. The regulation and fuel sulfur requirements were amended in 2011, as described above in Section 1.1.4.6.1 (Diesel Fuel Regulations). The regulation also establishes recordkeeping, reporting, and monitoring requirements.

1.1.5.6.10 CARB At-Berth Ocean-Going Vessels Regulation

On December 6, 2007, CARB approved the California Port Regulations for At-Berth Ocean-Going Vessels (CARB, 2007, 2013g), which requires operators of vessels meeting specified criteria to turn off auxiliary engines for most of their stay in port. For terminals that are providing electrical power from the electrical grid, the regulation requires ship fleets to reduce NO_x and PM emissions from auxiliary engines while at berth by 50% starting January 1, 2014, 70% in 2017, and 80% starting January 1, 2020. This regulation does not apply to tankers.

1.1.5.6.11 CARB Commercial Harbor Craft Regulation

Adopted in November 2007 and amended in June 2011, this regulation (CARB, 2005c, 2011d, 2014a) limits DPM, NO_x, and SO_x emissions from diesel propulsion and auxiliary engines on commercial harbor craft such as towboats and tugboats operated within California waters and within 24 nautical miles of the California coast. This regulation requires that new and in-use diesel-fueled harbor craft comply with the low sulfur fuel use requirement when operating within regulated California waters, as discussed above in Section 1.1.4.6.1 (Diesel Fuel Regulations). It also sets emission standards for new engines, as well as requirements and a schedule for the replacement or otherwise bringing into compliance pre-Tier 1 and Tier 1 engines for in-use fleets (ferries, excursion vessels, tugboats, towboats, push boats and multipurpose harbor craft) (CARB, 2008a, 2008c).

1.1.6 Regional (BAAQMD) and Local Plans, Programs, and Regulations

The BAAQMD attains and maintains air quality conditions in the SFBAAB. As shown in Figure A4.3-REG-1, and described in the California Code of Regulations, Title 17, Section 60101, the BAAQMD's jurisdiction encompasses all of seven counties – Alameda, Contra Costa, Marin, San Francisco, San Mateo, Santa Clara and Napa, and portions of two others – southwestern Solano and southern Sonoma. Figure A4.3-REG-2 shows the location of the Modernization Project.

The BAAQMD regulates air quality through a comprehensive program of planning, regulation, enforcement, technical innovation, and promotion of the public's understanding of air quality issues. The clean air strategy of BAAQMD includes the preparation of plans for the attainment of ambient air quality standards, adoption and enforcement of rules and regulations concerning sources of air pollution, and issuance of permits for stationary sources of air pollution. BAAQMD is the agency with permit, regulatory, and enforcement authority over most types of stationary emission sources in the Bay Area.

1.1.6.1 Summary of BAAQMD Rules and Regulations Related to Criteria Air Pollutants, Listed in the Facility's Title V Permit

There are many BAAQMD regulations that apply to the construction and operation of the Modernization Project. The regulations are contained in the BAAQMD Rules and Regulations, Volumes 1 and 2. The CAP regulations cited in the Facility's current Title V Operating Permit are detailed in Table 4.3-REG-4.

1.2 REGULATION OF TOXIC AIR CONTAMINANTS

Air quality regulations also focus on TACs (or in federal terminology, hazardous air pollutants [HAPs]). In California, TACs are defined by the CARB as those air

TABLE A4.3-REG-4 SUMMARY OF BAAQMD RULES AND REGULATIONS RELATED TO CRITERIA AIR POLLUTANTS, LISTED IN THE FACILITY'S TITLE V OPERATING PERMIT

BAAQMD Rule	Description
Regulation 1: General Provisions & Definitions	Outlines general provisions and definitions that apply to all other District Rules and Regulations.
Regulation 1, Rule2: Notice to Comply	Establishes guidelines for implementing and conducting a Notice to Comply element within the enforcement program. Sets standards for minor violations, immediate correction of minor violations, testing, and failure to comply.
Regulation 2, Rule 1: General Requirements	Includes requirements to obtain authority to construct and permit to operate; fee requirements; applicability of CEQA; requirements for new or modified sources of TACs or HAPs; public nuisance source requirements; hazardous substance requirements; permit conditions; appeals process; public notice requirements; loss of exemption requirements; source pre-certification procedure; revocation procedure; procedure for ministerial evaluations; federal emissions statement requirements.
Regulation 2, Rule 2: New Source Review	Applies to all new and modified stationary sources that require an Authority to Construct or a Permit to Operate. Provides for the review of new and modified sources and provide mechanisms, including the use of BACT and emission offsets, by which authorities to construct such sources may be granted. Includes PSD rules for NO_x, POCs, SO₂, CO, and PM₁₀, and if PSD is triggered, provides additional restrictions on asbestos, beryllium, mercury, fluorides, sulfuric acid mist, H₂S, total reduced sulfur, and total reduced sulfur compounds. For sources that require an Authority to Construct or a Permit to Operate, if emissions from a new source or increase in emissions from a modified source has the potential to emit 10 pounds or more per highest day of POC, non-precursor organic compounds, NO_x, SO₂, PM₁₀, or CO, BACT is required to be applied. Emissions offsets are required for new NO_x and POC emissions in accordance with Regulation 2-2-302 (facilities that emit more than 35 tons/yr). Offsets are also required for PM₁₀ and SO₂ emissions in excess of 1.0 ton/year in accordance with Regulation 3-2-303. BAAQMD regulations do not require that increases in CO emissions be offset. While there is no threshold for providing offsets for CO emissions, dispersion modeling requirements are specified for facilities with a cumulative increase of CO emissions in excess of 100 tons/yr. Modeling must show that the proposed project would not interfere with attainment or maintenance of the state CO standards. Revisions to this rule have been adopted by BAAQMD's Board of Directors (December 19, 2012) and submitted to EPA for approval. The revisions establish new NSR requirements for PM_{2.5}, revise the definition of "modification," and establish a new PSD program for sources in the SFBAAB (currently BAAQMD simply administers the federal PSD rules). The revised rule will not become effective until EPA approves it.

TABLE A4.3-REG-4 SUMMARY OF BAAQMD RULES AND REGULATIONS RELATED TO CRITERIA AIR POLLUTANTS, LISTED IN THE FACILITY'S TITLE V OPERATING PERMIT

BAAQMD Rule	Description
Regulation 2, Rule 4: Emissions Banking	Provides for acquisition of emission offsets under the New Source Review regulation. Defines different types of bankable reductions, non-eligible emission reductions, and limitations on banking transactions. Includes guidelines for banking applications, decisions on applications, publication and public comment, and duration of deposits. Also includes guidelines on the creation and operation by the district of a small facility banking account to grant offsets to small facilities.
Regulation 2, Rule 6: Major Facility Review	Implements the operating permit requirements of Title V of the FCAA as amended in 1990. It requires any facility to apply for a Major Facility Review Permit if it has a potential to emit criteria pollutants in excess of 100 tons/yr, or any single hazardous air pollutant in excess of 10 tons/yr, or any combination of HAPs in excess of 25 tons/yr. A major facility review involves a plant-wide review of sources, emissions, and regulatory requirements. This rule also provides a means by which facilities may avoid the Title V or other requirements by limiting their potential to emit.
Regulation 2, Rule 9: Interchangeable Emission Reduction Credits	Provides a method to calculate and track the generation, use and trading of Interchangeable Emission Reduction Credits from stationary sources of NO _x , in order to provide an alternate means of compliance with certain District NO _x rules and regulations.
Regulation 4: Air Pollution Episode Plan	Describes system designed to reduce levels of air contaminants that may reach or have reached the level that may be harmful to health, and to protect that portion of the population at risk. Includes control and advisory procedures when specified pollutant concentrations have been reached.
Regulation 5: Open Burning	Prohibits open burning with certain exemptions including agricultural burning, hazardous materials disposal, fire training, and range/forest/wildlife management.
Regulation 6, Rule 1: General Requirements	Limits the quantity of PM in the atmosphere through the establishment of limitations on emission rates, concentration, visible emissions, and opacity. Includes source specific requirements for tube cleaning, sulfuric acid manufacturing plants, and sulfur recovery units; sampling facilities and instruments requirements; and data, records, and reporting requirements.
Regulation 8, Rule 1: General Provisions	Limits the emissions of organic compounds to the atmosphere. Includes standards for surface preparation; clean-up; coating, ink, and paint removal; closed containers; and spray equipment clean-up.
Regulation 8, Rule 2: Miscellaneous Operations	Reduces emissions of POCs from miscellaneous operations. Includes limits on total carbon emissions on mass basis and concentration basis.
Regulation 8, Rule 3: Architectural Coatings	Limits the quantity of VOCs in architectural coatings supplied, sold, offered for sale, applied, solicited for application, or manufactured for use with the District. Includes VOC content limits by coating category that apply before and after January 1, 2011; painting practices and requirements for solvent usage and storage; container labeling requirements; and monitoring and recordkeeping requirements.

TABLE A4.3-REG-4 SUMMARY OF BAAQMD RULES AND REGULATIONS RELATED TO CRITERIA AIR POLLUTANTS, LISTED IN THE FACILITY'S TITLE V OPERATING PERMIT

BAAQMD Rule	Description
Regulation 8, Rule 4: General Solvent and Surface Coating Operations	Limits VOC emissions from the use of solvents and surface coatings in such operations as: model making, printed circuit board manufacturing, electrical and electronic component manufacturing, surface coating of test panels, training facilities for coating, stencil coatings, coatings and coating activities exempt from other Regulation 8 Rules, or solvent usage not specified by other Regulation 8 Rules.
Regulation 8, Rule 5: Storage of Organic Liquids	Applies to facilities that store organic compounds. Depending on the size of the tank and the type of material stored, each tank is required to be equipped with a vapor loss control device with at least 95% abatement efficiency, in addition to other tank-specific requirements related to fittings, seals, and valves.
Regulation 8, Rule 6: Terminals and Bulk Plants	Limits emissions of certain organic compounds from transfer operations at non-gasoline organic liquid bulk terminals and bulk plants.
Regulation 8, Rule 7: Gasoline Dispensing Facilities	Limits organic compound emissions from gasoline dispensing facilities.
Regulation 8, Rule 8: Wastewater (Oil-Water) Separators	Limits emissions of organic compounds from wastewater collection and suspiration systems that handle liquid organic compounds from industrial processes.
Regulation 8, Rule 9: Vacuum Producing Systems	Limits emission of precursor organic compounds from vacuum producing systems.
Regulation 8, Rule 10: Process Vessel Depressurization	Applies to petroleum refineries and chemical plants with process vessels. Set operational requirements and restrictions for depressurization of process vessels, as well as recording and reporting requirements.
Regulation 8, Rule 15: Emulsified and Liquid Asphalts	Limit the emissions of VOCs associated with emulsified and liquid asphalt in paving materials and paving and maintenance operations.
Regulation 8, Rule 16: Solvent Cleaning Operations	Includes vapor solvent cleaner requirements; cold cleaner requirements; and recordkeeping requirements. Limited exemptions for various sources/operations.
Regulation 8, Rule 18: Equipment Leaks	Limits emissions of organic compounds and methane from leaking equipment at petroleum refineries, including those associated with, but not limited to, valves, connectors, pumps, compressors, pressure relief devices, diaphragms, hatches, sight-glasses, fittings, sampling ports, meters, pipes and vessels.
Regulation 8, Rule 19: Surface Preparation and Coating of Miscellaneous Metal Parts and Products	Limits VOC emissions from surface preparation and coating of miscellaneous metal parts and products.
Regulation 8, Rule 28: Episodic Releases from	Prevents episodic emissions of organic compounds from pressure relief devices on equipment handling gaseous organic compounds at petroleum refineries, and collects information on

TABLE A4.3-REG-4 SUMMARY OF BAAQMD RULES AND REGULATIONS RELATED TO CRITERIA AIR POLLUTANTS, LISTED IN THE FACILITY'S TITLE V OPERATING PERMIT

BAAQMD Rule	Description
Pressure Relief Devices at Petroleum Refineries and Chemical Plants	episodic organic and inorganic compound emissions from pressure relief devices at petroleum refineries and chemical plants.
Regulation 8, Rule 31: Surface Preparation and Coating of Plastic Parts and Products	Limits VOC emissions from the surface preparation and coating of plastic parts and products.
Regulation 8, Rule 32: Wood Products Coatings	Limits VOC emissions from the coating of wood products, including surface preparation, application of coatings, and cleanup.
Regulation 8, Rule 33: Gasoline Bulk Terminals and Gasoline Cargo Tanks	Limits VOC emissions associated with gasoline transfer operations at gasoline bulk terminals, and VOC emissions from gasoline cargo tanks.
Regulation 8, Rule 40: Aeration of Contaminated Soil and Removal of Underground Storage Tanks	Limit the emission of organic compounds from soil that has been contaminated by organic chemical or petroleum chemical leaks or spills, and to describe an acceptable procedure for controlling emissions from underground storage tanks during removal or replacement.
Regulation 8, Rule 44: Marine Tank Vessel Operations	Limits the emission of organic compounds into the atmosphere from marine tank vessel loading and lightering, ballasting, and venting operations to 2 pounds per 1,000 barrels of organic liquid loaded, or reduce emissions by at least 95% by weight from uncontrolled conditions. Also specifies recordkeeping requirements.
Regulation 8, Rule 47: Air Stripping and Soil Vapor Extraction Operations	Limit emissions of organic compounds from contaminated groundwater and soil; applies to new and modified air stripping and soil vapor extraction equipment used for the treatment of groundwater or soil contaminated with organic compounds.
Regulation 8, Rule 49: Aerosol Paint Products	Limits emissions of organic compounds from the use of hand-held aerosol paint products.
Regulation 8, Rule 51: Adhesive and Sealant Products	Limits the emissions of organic compounds from adhesive and sealant products. Any operation determined to be exempt from this Rule shall be subject to the provisions of Rule 4, if not already subject to another Rule of Regulation 8.
Regulation 9, Rule 1: Sulfur Dioxide	Sets SO ₂ emission limitations for all sources, including ships; and sets restrictions on fuel sulfur content. This rule also outlines specific requirements related to sulfur content and sulfur removal efficiencies for sulfur removal operations at petroleum refineries.
Regulation 9, Rule 2: Hydrogen Sulfide	Set limits on ground level H ₂ S concentrations, and specifies monitoring and recordkeeping requirements.

TABLE A4.3-REG-4 **SUMMARY OF BAAQMD RULES AND REGULATIONS RELATED TO CRITERIA AIR POLLUTANTS, LISTED IN THE FACILITY'S TITLE V OPERATING PERMIT**

BAAQMD Rule	Description
Regulation 9, Rule 3: Nitrogen Oxides from Heat Transfer Operations	Limits NO _x emissions from existing, new or modified heat transfer operations, by regulating NO _x level in exhaust.
Regulation 9, Rule 7: Nitrogen Oxides and Carbon Monoxide from Industrial, Institutional, and Commercial Boilers, Steam Generators, and Process Heaters	Limits NO _x and CO emissions from industrial, institutional and commercial boilers, steam generators and process heaters, by limiting concentrations in exhaust. Also sets stack gas temperature limits, and registration and recordkeeping requirements.
Regulation 9, Rule 8: Nitrogen Oxides and Carbon Monoxide from Stationary Internal Combustion Engines	Limits NO _x and CO emissions from stationary internal combustion engines with an output rated by the manufacturer at more than 50 brake horsepower. Facilities are also required to comply with the monitoring and recordkeeping requirements.
Regulation 9, Rule 9: Nitrogen Oxides from Stationary Gas Turbines	Requires specific NO _x emission limits for gas turbines. Facilities are also required to comply with the monitoring and recordkeeping requirements.
Regulation 9, Rule 10: Nitrogen Oxides and Carbon Monoxide from Boilers, Steam Generators, and Process Heaters in Petroleum Refineries	Applies NO _x and CO emission limits to industrial process heaters, and sets monitoring, recordkeeping, and reporting requirements.
Regulation 10: Standards of Performance for New Stationary Sources	Discussion is provided in paragraphs following this table.
Regulation 11, Rule 1: Lead	Requires a daily lead emission limit of 15 pounds, and limits ground level concentrations to 1.0 µg/m ³ averaged over 24 hours. Controls emissions of lead into the atmosphere. Includes daily lead emission limitation; ground level lead concentration limits with and without background; and monitoring.
Regulation 12, Rule 4: Sandblasting	Sets performance standards and Ringelmann limits for sandblasting operations other than permanent abrasive blasting operations or equipment.
Regulation 12, Rule 11: Flare Monitoring at Petroleum Refineries	Requires refineries to accurately monitor and submit reports of the flow and composition of vent gases sent to and combusted by a flare. Chevron is required to report reasons for significant flaring events (flow rate greater than 1 million scf in a 24-hour period) as well as any corrective actions taken to reduce or prevent them.

TABLE A4.3-REG-4 SUMMARY OF BAAQMD RULES AND REGULATIONS RELATED TO CRITERIA AIR POLLUTANTS, LISTED IN THE FACILITY’S TITLE V OPERATING PERMIT

BAAQMD Rule	Description
Regulation 12, Rule 12: Flares at Petroleum Refineries	Required refineries to prepare and implement a FMP on or before August 1, 2006. The FMP defines a series of measures intended to reduce flaring to the extent that is feasible without compromising safety and necessary Facility operations and practices. The key tools utilized are planning to minimize flaring, coupled with evaluation of the cause of any flaring events that do occur. The FMP also examines the costs and benefits of potential equipment modifications to increase flare gas recovery. The FMP for the Facility approved by BAAQMD. ⁴ In addition, refineries are required to identify reasons for reportable flaring events (flow rate greater than 500,000 scf or greater than 500 pounds SO ₂ emission in a calendar day) and take corrective actions to prevent them. This is consistent with the recently signed final NSPS subpart Ja, which requires root cause analysis and corrective actions for such events. Chevron’s FMP was last submitted to BAAQMD on June 14, 2012.
Proposed Regulation 12, Rule 15: Petroleum Refining Emissions Tracking	The proposed new BAAQMD rule would require that if refinery emissions (including criteria pollutants, TACs, and greenhouse gases) increase beyond specified trigger levels, the refinery would be required to reduce emission increases to below the trigger levels, based on a BAAQMD-approved emissions reduction plan. The rule would also require refineries to establish new monitoring systems to help better quantify and understand how refinery air emissions affect the public.

Notes: FMP = flare minimization plan
HAP = hazardous air pollutant
NSR = New Source Review
POC = precursor organic compound
scf = standard cubic feet
VOC = volatile organic compound
µg/m³ = micrograms per cubic meter

pollutants that “may cause or contribute to an increase in deaths or in serious illness, or which may pose a present or potential hazard to human health” (CARB, 2014b). There are currently over 200 substances that have been identified by the CARB as TACs (CARB, 2011i). While most TACs originate from human sources such as fossil fuel combustion or dry cleaning facilities, natural sources such as forest fires and volcanic eruptions also contribute TACs to ambient air.

The nature and magnitude of the potential health effects of TACs depends on the substance, the concentration, and the period of exposure. Some TACs cause effects in response to short-term (acute) exposure; others cause effects only after sustained exposures over weeks, months, or years. The effects of acute exposure may be minor, such as watery eyes or respiratory irritation; or they

may involve damage such as to the reproductive system or nervous system. If exposure to a sufficient concentration occurs for a sufficient period, individuals may have an increased risk of developing cancer, or a greater likelihood of experiencing non-carcinogenic chronic adverse effects. These chronic non-carcinogenic health effects may be minor, such as nasal rhinitis or respiratory irritation; or they may involve long-term damage to the immune, neurological, reproductive, respiratory, or other systems (EPA, 2012e).

1.2.1.1 BAAQMD Standards of Performance for New Stationary Sources Listed in the Facility's Title V Permit

BAAQMD Regulation 10 (amended February 16, 2000) establishes emission and/or performance standards for new plants and other modified or reconstructed sources by incorporating the provisions of 74 subparts of 40 CFR 60. Table A4.3-REG-5 summarizes the federal regulatory subparts incorporated into this BAAQMD regulation that appear in the Facility's current Title V Permit. BAAQMD modifications to the performance standards are also listed in the table.

While some natural sources such as forest fires and volcanic eruptions contribute TACs to ambient air, most TACs originate from anthropogenic sources. Industrial facilities and mobile sources are significant sources of TACs. Various common urban facilities also produce TAC emissions, such as gasoline stations (benzene), hospitals (ethylene oxide), and dry cleaners (perchloroethylene). Automobile exhaust also contains TACs such as benzene and 1,3-butadiene. Most recently, DPM was identified as a TAC by CARB. DPM is a complex mixture of hydrocarbons, particulates, gases, and other compounds (OEHHA, 1998). DPM is emitted by diesel-fueled internal combustion engines, and the composition of the emissions varies depending on engine type, operating conditions, fuel composition, lubricating oil, and whether an emission control system is present. Both California's Office of Environmental Health Hazard (OEHHA) and the EPA consider DPM to be a carcinogen (OEHHA, 2009; EPA, 2011a). Both agencies also recognize that exposure to DPM may cause non-cancer effects such as change(s) in lung function and airway inflammation. DPM is a component of PM, and recent scientific data have linked prolonged exposure to PM to premature mortality, respiratory effects, and cardiovascular disease (Krewski et al., 2000; Pope et al., 2004, 2002).

For TACs that do not cause cancer, threshold levels of chemicals are established by OEHHA, which are thought to be safe. However, in general, for those TACs that may cause cancer, even the smallest concentrations of chemicals may

TABLE A4.3-REG-5 SUMMARY OF SUBPARTS FROM 40 CFR PART 60 REFERENCED IN THE FACILITY'S CURRENT TITLE V PERMIT THAT ARE INCORPORATED INTO BAAQMD REGULATIONS

40 CFR Part 60		
Subpart	Description	BAAQMD Modification
A	General Provisions	–
D	Standards of Performance for Fossil-Fuel-Fired Steam Generators	–
Db	Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units	The 30-day emissions averaging periods specified in the federal standard are deleted and replaced with 24-hour maximum emissions averaging periods for affected facilities in the BAAQMD.
Dc	Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units	–
J	Standards of Performance for Petroleum Refineries	–
Kb	Standards of Performance for Volatile Organic Liquid Storage Vessels	Any violation of provision 60.113.b, testing procedures, determined by air pollution control personnel, shall constitute a violation of subpart Kb.
GG	Standards of Performance for Stationary Gas Turbines	–
VV	Standards of Performance for Equipment Leaks of VOC in the Synthetic Organic Chemicals Manufacturing Industry for which Construction, Reconstruction, or Modification Commenced After January 5, 1981, and on or Before November 7, 2006	–
GGG	Standards of Performance for Equipment Leaks of VOC in Petroleum Refineries for which Construction, Reconstruction, or Modification Commenced After January 4, 1983 and on or Before November 7, 2006	–
QQQ	Standards of Performance for VOC Emission From Petroleum Refinery Wastewater Systems	–

Notes: VOC = volatile organic compound

present some risk of cancer. In other words, there is no threshold level below which adverse health risks, although potentially small, may not be estimated to occur for carcinogenic chemicals. This is in contrast with the CAPs, for which acceptable levels of exposure can be determined and for which ambient standards have been established (refer to Table A4.3-REG-2). The EPA and CARB regulate TACs through statutes and regulations that generally require the use of the maximum or best available control technology for toxics (Maximum Achievable Control Technology [MACT] and Best Available Control Technology for Toxics [T-BACT], respectively) to limit emissions. These, in conjunction with additional rules set forth by BAAQMD, establish the regulatory framework for TACs.

An example of a chronic, non-carcinogenic disorder exacerbated by air pollutants is asthma, which has been the focus of a number of recent studies. While there is only limited evidence that air pollution is the causative factor in asthma onset, there are considerable data that link air pollution to worsening of the disease. For example, living near traffic sources has been associated with both asthma occurrence and aggravation of the disease (Salam et al., 2008), and others reported a significant increase in hospital visits as exposure to traffic increased (Chang et al., 2009). Proximity to heavy traffic has also been linked to impaired lung development in children (Gauderman et al., 2007).

Unlike criteria pollutants, TACs do not have region-wide ambient concentration limits such as NAAQS or CAAQS; there is no equivalent to “attainment status” for TACs. Concentrations of TACs may be regulated indirectly based on results from a HRA. An HRA is a scientifically based tool used to determine if exposure to chemicals(s) pose a significant risk (cancer risk or non-cancer hazards) to human health. The effects of air toxic emissions are relatively localized, with concentrations tending to decrease markedly with distance from the source due to dilution and/or degradation. Due to this localized nature, HRAs tend to focus on receptors in the immediate vicinity of the point of release.

1.2.2 Federal Regulations

1.2.2.1 National Emission Standards for Hazardous Air Pollutants (40 CFR Part 61 and 40 CFR Part 63)

The FCAA Amendments of 1970 required the EPA to identify and list all air pollutants (not already identified as criteria pollutants) that “may reasonably be anticipated to result in an increase in mortality or an increase in serious irreversible or incapacitating reversible illness.” The standards for TACs were considerably strengthened under the FCAA Amendments with the listing of 189 HAPs. For each HAP identified, the EPA was to then promulgate National Emissions Standards For Hazardous Air Pollutants (NESHAPs) at levels that would ensure the protection of the public health with an ample margin of safety and to

prevent any significant and adverse environmental effects, which may reasonably be anticipated, on wildlife, aquatic life, or other natural resources (EPA, 2011b). The NESHAPS can set different requirements for major and area sources. Major sources are defined as stationary sources with potential to emit more than 10 tons/yr of any HAP or more than 25 tons/yr of any combination of HAPs; all other sources regulated under Title III of the FCAA Amendments are considered area sources. Issuance of the emission standards occurs in two phases. The first phase consists of technology-based emission standards designed to produce a high level of emission reductions for major sources of HAPs, which are referred to as MACT standards. For area sources, the standards may be different, based on generally available control technology. In the second phase, the EPA must issue health risk-based emissions standards where such standards are deemed necessary to address risks remaining after implementation of the technology-based NESHAPS. These second-phase standards are generally referred to as “residual MACT” standards.

The FCAA Amendments also required the EPA to issue vehicle or fuel standards containing reasonable requirements to control HAP emissions, applying at a minimum to benzene and formaldehyde. Performance criteria were established to limit mobile source emissions of toxics, including benzene, formaldehyde, and 1,3-butadiene. In addition, Section 219 of the FCAA Amendments also required the use of reformulated gasoline in selected U.S. cities (those with the most severe O₃ nonattainment conditions) to further reduce mobile-source emissions, including air toxics. Many of the regulations described in Section 1.1.3.6 of this appendix (Federal Mobile and Marine Source Regulations) were designed to address TACs as well as criteria pollutants.

The federal hazardous air pollutant regulations that are cited in the Facility’s current Title V Operating Permit are listed below and described in Table A4.3-REG-6.

1.2.2.2 Toxic Release Inventory (40 CFR Part 372)

Toxic Chemical Release Inventory Reporting is part of the Emergency Planning and Community Right-to-Know Act (EPCRA), which is intended to alert the public of emergency releases of chemicals by requiring facilities to report releases. This allows planning for emergencies, as well as addresses the public right-to-know. Under EPCRA, any facility with more than 10 employees that manufactures, processes, or otherwise uses certain chemicals in amounts greater than a specified threshold is required to submit an annual toxic chemical release report. The EPA then compiles these annual toxic chemical release forms and the national Toxic Release Inventory (TRI) database (EPA, 2014).

TRI database is the most comprehensive national source of information about toxic chemical releases. However, TRI may not accurately represent the actual

**TABLE A4.3-REG-6 SUMMARY OF FEDERAL HAPs REGULATIONS CITED IN FACILITY'S
TITLE V PERMIT**

CFR Part	Subpart	Description	Details
40 CFR Part 61	A	General Provisions	Lists designated hazardous air pollutants; requires notification and application for approval of construction and operation of sources; prohibits circumvention of sources; includes definitions and requirements for source reporting, emission testing, monitoring, recordkeeping and reporting, to which subparts can incorporate by reference or can override.
40 CFR Part 61	J	National Emission Standard for Equipment Leaks (Fugitive Emission Sources) of Benzene	Sets design, operational and monitoring requirements for equipment used in benzene service (i.e., contains or contacts process fluid with 10% benzene by weight); also describes recordkeeping and reporting requirements.
40 CFR Part 61	M	National Emission Standard for Asbestos	Applies to each owner or operator of a demolition or renovation activity. Includes notification requirements and emission control procedures. Standards for waste disposal; visible emissions discharge restrictions; waste material disposal requirement; marking requirements for asbestos-containing waste material transporting vehicle; and record keeping requirements for asbestos-containing waste material transportation. Includes reporting requirements for emission control equipment for new sources, unreported existing sources, and existing source modifications. Some exemptions apply based on the removal amount of regulated asbestos-containing material and on the reason and purpose of the demolition.
40 CFR Part 61	V	National Emission Standards for Equipment Leaks (Fugitive Emission Sources)	Sets design, operational and monitoring requirements for equipment used in volatile hazardous air pollutant service (i.e., contains or contacts process fluid with 10% volatile hazardous air pollutants by weight); also describes recordkeeping and reporting requirements.
40 CFR Part 61	FF	National Emission Standards for Benzene Waste Operations	Sets requirements on management and treatment of waste containing benzene; operating and design requirements for equipment and processes associated with benzene waste operations; and monitoring, reporting and recordkeeping. Applies to chemical manufacturing plants, coke by-product recovery plants, and petroleum refineries.
40 CFR Part 63	A	General Provisions	Establishes applicability determination for stationary sources; prohibits circumvention and fragmentation of sources; includes definitions and requirements for preconstruction review and notification, performance testing, monitoring, recordkeeping and reporting, to which subparts

**TABLE A4.3-REG-6 SUMMARY OF FEDERAL HAPs REGULATIONS CITED IN FACILITY'S
TITLE V PERMIT**

CFR Part	Subpart	Description	Details
			can incorporate by reference or override.
40 CFR Part 63	H	National Emission Standards for Organic Hazardous Air Pollutants for Equipment Leaks	Sets design, operational and monitoring requirements for equipment used in organic hazardous air pollutant service 300 hours or more during the calendar year; also describes recordkeeping and reporting requirements.
40 CFR Part 63	R	National Emission Standards for Gasoline Distribution Facilities (Bulk Gasoline Terminals and Pipeline Breakout Stations)	Sets operating and design standards on loading racks, storage vessels and equipment leaks associated with bulk gasoline terminals and pipeline breakout stations. Includes monitoring, recordkeeping and reporting requirements.
40 CFR Part 63	Y	National Emission Standards for Marine Tank Vessel Loading Operations	Sets operating and design standards for marine vessel loading, including monitoring, recordkeeping and reporting requirements.
40 CFR Part 63	CC	National Emission Standards for Hazardous Air Pollutants for Petroleum Refineries	Set operating, design and emission standards as well as monitoring, recordkeeping and reporting requirements for various types of sources in a petroleum refinery, including miscellaneous process vents; storage vessels; equipment leaks; marine tank vessel loading operations; heat exchanger systems; and wastewater units. Includes cross-references to other Subparts.
40 CFR Part 63	UUU	National Emission Standards for Hazardous Pollutants for Petroleum Refineries: Catalytic Cracking Units, Catalytic Reforming Units, and Sulfur Recovery Units	Establishes HAP emission standards from catalytic cracking units, catalytic reforming units, and sulfur recovery units (such as concentration limits from process vents), and establishes requirements for monitoring, recordkeeping, reporting/notification, and demonstrating compliance.
40 CFR Part 63	YYYY	National Emission Standards for Hazardous Air Pollutants for Stationary Combustion Turbines	Sets formaldehyde emission limit and operating conditions for stationary combustion turbines (such as in cogeneration units) and establishes requirements for monitoring, record keeping, reporting/notification, and demonstrating compliance.
40 CFR Part 63	ZZZZ	National Emission Standards for Hazardous Air Pollutants For Stationary Reciprocating Internal Combustion Engines	Start-up requirements for Reciprocating Internal Combustion Engines (RICE) at area sources; numerical CO emission standards (except during startup) for stationary non-emergency RICE at area sources; management practices (air/filter replacement schedule, inspection schedule) listed in this regulation (or in conjunction with an alternative management program administered by State permitting authorities), for

TABLE A4.3-REG-6 SUMMARY OF FEDERAL HAPs REGULATIONS CITED IN FACILITY'S TITLE V PERMIT

CFR Part	Subpart	Description	Details
			stationary emergency RICE and non-emergency RICE less than or equal to 300 HP; requirements for crankcase ventilation or emission control systems for stationary non-emergency RICE units greater than 300 hp; compliance testing and reporting and recordkeeping requirements.
40 CFR Part 63	DDDDD	National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters	Sets HAP emissions limitations and work practice standards for new and existing boilers and process heaters at major sources. This subpart also establishes requirements to demonstrate compliance with the emissions limitations and work practice standards.
40 CFR Part 63	GGGGG	National Emission Standards for Hazardous Air Pollutants: Site Remediation	Sets HAP emissions limitations and work practice standards for site remediation activities and associated equipment (e.g., tanks, process vents, surface impoundments, containers, separators). This subpart also establishes requirements to demonstrate compliance with the emissions limitations and work practice standards.

Notes: RICE = Reciprocating Internal Combustion Engines

Although 40 CFR 63 Subpart Q (MACT for Industrial Process Cooling Towers) is mentioned in the Title V permit, the Facility has not used chromium based water treatment since 1989, and thus is expected to continue to comply with the requirements of 40 CFR Part 63 Subpart Q.

amount released, because TRI reporting does not require emission monitoring and companies may estimate their releases using factors of varying quality. TRI is not inclusive of all the emission sources and some emissions sources may be excluded through de minimis exemption, as facilities are not required to report if a listed chemical is present at concentrations of less than 1.0% (or 0.1% for carcinogen) by weight in products received or manufactured by facilities.

TRI database categorizes the air releases of toxic chemicals as fugitive air and stack air. In the most recent TRI report year (2011), there are a total of 593 individually listed chemicals and 30 chemical categories that are subject to reporting. The EPA included these chemicals on the TRI list based on the acute human health risks, cancer or chronic (non-cancer) human health effects and/or environmental effects criteria set forth in EPCRA Section 313(d)(2). Some of the TRI chemicals are also TACs as defined by CARB and/or HAPs as defined by the EPA at the federal level (CDPH, 2010). There are currently over 200 TACs and

HAPs, with many of the pollutants overlapping as both a California TAC and a federal HAP.

1.2.2.3 Chemical Accident Prevention Provisions (40 CFR Part 68)

Section 112(r) of the 1990 FCAA Amendments requires facilities that handle listed substances to develop Risk Management Programs (RMPs), in order to prevent accidental releases of these chemicals. RMPs consist of three main elements: a hazards assessment, including off-site consequences analyses and a 5-year accident history; an accident prevention program; and an emergency response program. These programs are discussed in more detail in the Public Safety Section.

1.2.3 State Regulations

1.2.3.1 Tanner Air Toxics Act and AB 2588

TACs in California are primarily regulated through the Tanner Air Toxics Act (Assembly Bill [AB] 1807) and the Air Toxics Hot Spots Information and Assessment Act of 1987 (AB 2588, or the Hot Spots Act). AB 1807 sets forth a formal procedure for CARB to designate substances as TACs. Research, public participation, and scientific peer review are necessary before CARB can designate a substance as a TAC. To date, CARB has adopted the EPA's list of HAPs as TACs and has identified more than 20 additional TACs.

Once a TAC is identified, CARB then adopts an ATCM for sources that emit that particular TAC. If there is a safe threshold at which there is no toxic effect from a substance, the control measure must reduce exposure below that threshold. If there is no safe threshold, the measure must incorporate BACT to minimize emissions.

The Hot Spots Act, AB2588, requires that existing facilities that emit toxic substances above a specified level prepare a toxic-emissions inventory and a risk assessment if emissions are significant, notify the public of significant risk levels, and prepare and implement risk reduction measures.

1.2.3.2 California Accidental Release Prevention Program (CCR Title 19, Division 2, Chapter 4.5)

The California Health and Safety Code (Article 2, Chapter 6.95) requires facilities that handle listed substances above a specified threshold quantity to develop Risk Management Plans to prevent accidental releases of these chemicals and minimize the damage from accidental releases that do occur. These programs are discussed in more detail in the Public Safety section.

1.2.3.3 Proposition 65

The Safe Drinking Water and Toxic Enforcement Act of 1986, Proposition 65, was passed as a ballot initiative in 1986 and is intended to protect citizens and the State's drinking water from chemicals known to cause cancer or reproductive toxicity (including birth defects), as well as to notify citizens about their exposure to such chemicals.

The Facility provides Proposition 65 warnings for listed chemicals by posting warning signs at the Project site as well as by quarterly warning notices published by the Western States Petroleum Association in approximately 80 general circulation newspapers and periodicals. The Richmond Post, Contra Costa Times, Oakland Tribune, and San Francisco Chronicle are some of the local newspapers the Western States Petroleum Association notice is published in. The warnings include information about potential health effects of an exposure, locations of potential exposure, and a telephone number for people to call to obtain more information.

1.2.3.4 Diesel Risk Reduction Plan

In August 1998, the CARB identified DPM (i.e., PM from diesel-fueled engines) as a TAC. After identifying DPM as a TAC, CARB adopted a comprehensive Risk Reduction Plan in 2000 (CARB, 2000c). Pursuant to this Plan, CARB adopted diesel-exhaust control measures and stringent emission standards for various on-road mobile sources of emissions, including transit buses and off-road diesel equipment (e.g., tractors, generators). In 2001, CARB adopted the Public Transit Bus Fleet Rule and Emissions Standards for New Urban Buses, which established emissions limits on 1985 and subsequent model year heavy-duty bus engines and vehicles for NO_x, CO, nonmethane hydrocarbons, PM, and formaldehyde. The emissions standards apply to all heavy-duty urban buses, including diesel-fueled buses. Therefore, the rule limits the emissions of two TACs identified by CARB: DPM and formaldehyde. In 2007, a low-sulfur diesel fuel requirement and tighter emission standards for heavy-duty diesel trucks was put into effect, followed in 2011 by the same standards being applied to off-road diesel equipment.

Over time, the replacement of older vehicles will result in a fleet that produces substantially lower levels of TACs than the replaced vehicles. Mobile-source emissions of TACs (e.g., benzene, 1,3-butadiene, DPM) decreased significantly over the last decade and will be reduced further in California through a progression of regulatory measures (e.g., Low-Emission Vehicle/Clean Fuels and Phase II reformulated gasoline regulations) and control technologies. The California Port Regulations for At-Berth Ocean-Going Vessels (approved in 2007) requires operators of vessels meeting specified criteria to turn off auxiliary engines for most of their stay in port. The Commercial Harbor Craft Regulation adopted in

November 2007 and amended in June 2011 limits DPM emissions from commercial harbor craft operating within California waters and within 24 nautical miles of the California coast. This regulation sets emission standards for new engines, as well as requirements for replacement or retrofitting of pre-Tier 1 and Tier 1 engines for in-use fleets (CARB, 2008b, 2008c).

With implementation of CARB's Risk Reduction Plan, DPM concentrations are expected to be reduced by 75% in 2010 and 85% in 2020 from the estimated year-2000 level. As emissions are reduced, it is expected that risks associated with exposure to the emissions will also be reduced. Emissions from heavy-duty diesel equipment associated with Chevron would be required to comply with the rules outlined above. Details regarding the regulations adopted pursuant to the CARB's Risk Reduction Plan are discussed earlier in this appendix.

1.2.3.5 Air Quality and Land Use Handbook

CARB, 2005a provides guidance concerning land-use compatibility with TAC sources. Although not a law or adopted policy, the handbook offers recommendations for the siting of sensitive receptors (e.g., proposed residential units) near uses associated with TACs to help limit the exposure of children and other sensitive populations to TACs. The Modernization Project does not involve siting of new sensitive land uses.

1.2.4 Regional (BAAQMD) and Local Plans, Programs, and Regulations

1.2.4.1 BAAQMD CARE Program

Under the Community Air Risk Evaluation (CARE) program, BAAQMD aims to identify areas (referred to in this context as "priority" or "impacted" communities) with high TAC emissions and sensitive populations that could be affected by them, and to use this information to establish policies and programs to reduce TAC emissions and exposures (BAAQMD, 2011). The six impacted communities are located in Concord, Richmond/San Pablo, San Jose, eastern San Francisco, western Alameda County, and Redwood City/East Palo Alto (BAAQMD, 2006b).

The main objectives of the program are to:

- Evaluate potential health risks associated with exposure to TACs from both stationary and mobile sources;
- Assess potential exposures to sensitive receptors and identify impacted communities;
- Prioritize TAC reduction measures for significant TAC sources in impacted communities; and

- Develop and implement mitigation measures - such as grants, guidelines, or regulations - to improve air quality, focusing initially on priority communities.

During Phases I and II of the CARE program, BAAQMD developed a preliminary Bay Area-wide TAC emissions inventory, compiled demographic and health-statistics data, and conducted regional computer modeling of selected TAC species to identify communities that are disproportionately impacted from high concentrations of TACs. Details on these analyses are presented in *Appendix 4.3-PHYS*. During Phase III, BAAQMD will compare impacted communities with respect to risks from TACs, and identify sources that are the greater contributors to risk. BAAQMD will also pursue mitigation measures and develop methods to assess their effectiveness in reducing overall exposures.

1.2.4.2 BAAQMD Work Plan for Action Items Related to Accidental Releases from Industrial Facilities

Approved by BAAQMD in October 2012 in response to the August 6, 2012, fire at the Project site, this work plan identifies and sets an implementation schedule for action items, most of which were to begin implementation by early 2013. These action items include: reviewing and updating BAAQMD incident response procedures; evaluating enhancements to air quality monitoring capabilities, community outreach related to incidents, and incident response resources; amending fee regulations to fund incident response resources; developing a new rule for emissions tracking, mitigation, and community air monitoring at refineries; continuing the August 6th incident investigation to take appropriate enforcement action; and seeking authority to apply more substantial penalties for accidental releases (BAAQMD, 2012a). The draft Regulation 12, Rule 15: Petroleum Refining Emissions Tracking is one product of this work plan.

1.2.4.3 BAAQMD Rules and Regulations

BAAQMD has implemented specific rules and regulations that limit emissions from various sources, and that identify specific pollution reduction measures. Some emissions sources are further subject to legal requirements imposed through BAAQMD's permitting process.

Under BAAQMD Rule 2-1 (General Permit Requirements), Rule 2-2 (New Source Review [NSR]), and Rule 2-5 (NSR of TACs), all sources that have the potential to emit TACs are required to obtain permits from BAAQMD. Permits may be granted if the sources are constructed and operated in accordance with applicable regulations, including NSR standards and ATCMs. BAAQMD prioritizes TAC-emitting stationary sources based on the quantity and toxicity of the TAC emissions, and on the proximity of the facilities to sensitive receptors. BAAQMD analyzes sources that require a permit (e.g., performs health risk assessments) based on their potential to emit TACs. If

it is determined that the Modernization Project's emissions would exceed BAAQMD's threshold of significance for TACs, as identified below, the source has to implement BACT for TACs (T-BACT) to reduce emissions. BAAQMD's T-BACT measures apply to sources such as petroleum refineries, including individual Facility sources, such as storage tanks, furnaces, boilers, oil-water separators, and other emissions sources at refineries. If a source cannot reduce the risk below the threshold of significance even after implementing T-BACT, then BAAQMD will deny the permit. According to the BAAQMD Engineering Report, which is contained in *Appendix 4.3-EE*, "[n]one of the individual source emissions result in a cancer risk that is greater than one in a million, nor a chronic hazard that is greater than 0.20. At these risk levels, none of the sources trigger the requirement for T-BACT (Best Available Control Technology for Toxics)." BAAQMD permit requirements help to reduce emissions and related health impacts from new emissions sources, as well as from existing emissions sources by requiring them to apply new technology when retrofitting.

BAAQMD's Rule 2-2 for Prevention of Significant Deterioration (PSD) includes PSD thresholds for a limited number of TACs. The Modernization Project will not trigger PSD requirements based on any of the TAC emissions, including H₂S, sulfuric acid mist, and lead compounds. BAAQMD's permitting process applies to stationary sources. Properties that are exposed to elevated levels of TACs from nonstationary sources, and the nonstationary sources themselves (e.g., on-road vehicles), are not subject to air quality permits. Emissions controls on mobile sources are subject to regulations implemented at the federal and State levels by EPA and California Air Resources Board (CARB). respectively.

In addition, many BAAQMD rules and regulations that appear in the Facility's current Title V Operating Permit – and that were previously discussed in the CAP section – also serve to reduce TAC emissions. These include:

- Regulation 8, Rule 1: General Provisions
- Regulation 8, Rule 2: Miscellaneous Operations
- Regulation 8, Rule 3: Architectural Coatings
- Regulation 8, Rule 4: General Solvent and Surface Coating Operations
- Regulation 8 Rule 5 (Storage of Organic Liquids)
- Regulation 8, Rule 6: Terminals and Bulk Plants
- Regulation 8, Rule 7: Gasoline Dispensing Facilities
- Regulation 8, Rule 8: Wastewater (Oil-Water) Separators
- Regulation 8, Rule 9: Vacuum Producing Systems
- Regulation 8 Rule 10: Process Vessel Depressurization

- Regulation 8, Rule 15: Emulsified and Liquid Asphalts
- Regulation 8, Rule 16: Solvent Cleaning Operations
- Regulation 8 Rule 18: Equipment Leaks
- Regulation 8, Rule 19: Surface Preparation and Coating of Miscellaneous Metal Parts and Products
- Regulation 8, Rule 28: Episodic Releases from Pressure Relief Devices at Petroleum Refineries and Chemical Plants
- Regulation 8, Rule 31: Surface Preparation and Coating of Plastic Parts and Products
- Regulation 8, Rule 32: Wood Products Coatings
- Regulation 8, Rule 33: Gasoline Bulk Terminals and Gasoline Cargo Tanks
- Regulation 8 Rule 40: Aeration of Contaminated Soil and Removal of Underground Storage Tanks
- Regulation 8 Rule 44: Marine Tank Vessel Operations
- Regulation 8, Rule 47: Air Stripping and Soil Vapor Extraction Operations
- Regulation 8, Rule 49: Aerosol Paint Products
- Regulation 8, Rule 51: Adhesive and Sealant Products
- Regulation 9 Rule 2: Hydrogen Sulfide (BAAQMD, 1999)
- Regulation 11 Rule 1: Lead (BAAQMD, 1982)
- Regulation 12 Rule 11: Flare Monitoring at Petroleum Refineries (BAAQMD, 2003)
- Regulation 12 Rule 12: Flares at Petroleum Refineries

Some additional regulations related to TACs that are mentioned in the Facility's current Title V Operation Permit are listed in Table A4.3-REG-7 below:²

1.3 BAAQMD RULES AND REGULATIONS PERTAINING TO ODORS

With authorization from the state, BAAQMD has developed the following rules and regulations pertaining to odors:

² Regulation 11, Rule 10: Hexavalent Chromium Emissions from Cooling Towers is also mentioned in the Title V permit. The Refinery has not used chromium based water treatment since 1989, and is expected to continue to comply with the requirements of District Regulation 11, Rule 10.

TABLE A4.3-REG-7 BAAQMD REGULATIONS AND RULES RELATING TO TACs AND INCLUDED IN THE FACILITY'S TITLE V PERMIT

BAAQMD Rule	Description
Regulation 11, Rule 2: Asbestos Demolition, Renovation and Manufacturing	Requires EPA- and Cal/OSHA-certified inspector and take samples of suspected asbestos containing material (ACM) prior to commencing demolition or renovation. Specific work practices (e.g., wet methods) must be observed during any renovation, demolition or asbestos abatement involving any amount of regulated asbestos containing material (RACM).
Regulation 11, Rule 7: Benzene	Limits benzene emissions from the following sources intended to operate in benzene service; pumps, compressors, pressure relief devices, sampling connection systems, open-ended valves or lines, valves, flanges and other product accumulator vessels; and control devices or systems required by this Rule.
Regulation 11, Rule 12: National Emission Standard for Benzene Emissions from Benzene Transfer Operations and Benzene Waste Operations	Includes provisions from Title 40 of the Code of Federal Regulations Part 61 Subpart BB, "National Emission Standard for Benzene Emissions from Benzene Transfer Operations", and Subpart FF "National Emission Standard for Benzene Emissions from Benzene Waste Operations."

Source: BAAQMD, 2014.

- **Regulation 7 (Odorous Substances)** – This regulation places general limitations on odorous substances, and specific emission limitations on certain odorous compounds such as ammonia. These limitations are not applicable until 10 or more odor complaints are filed within a 90-day period and remain effective until no additional complaints have been filed for a year. In addition, maximum allowable emission concentrations for certain compounds are presented, and facilities are also required to comply with sample collection and analysis procedures.
- **Regulation 9, Rule 2** – This rule requires ground level H₂S emissions during a 24-hour period to be limited to 0.06 ppm or less for a 3-minute average, or 0.03 ppm or less for a 60-minute average.

1.4 POLICIES REGARDING ENVIRONMENTAL JUSTICE

1.4.1 Federal Executive Order 12898

Executive Order 12898, "Federal Actions to Address Environmental Justice in Minority Populations and Low-income Population" (EO 12898 or the Executive Order) (February 11, 1994) directs federal agencies to the greatest extent practicable and permitted by law to achieve the goal of environmental justice. The Executive Order provides that the identified federal agencies should accomplish this goal "by identifying and addressing, as appropriate,

disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations...” (Federal Register, 1994).

A Presidential memorandum accompanying the Executive Order, further directs the heads of departments and agencies to analyze the environmental effects of federal actions, including human health, economic and social effects when required by the National Environmental Policy Act (NEPA) and to address potentially disproportionate adverse effects on minority and low-income communities.

Here, the Modernization Project does not require any federal action or permitting and is not reliant on any federal funds. Therefore, the Modernization Project is not subject to NEPA and is not subject to a federal environmental justice analysis.

1.4.2 State Regulations

The State of California has defined “Environmental Justice” as “the fair treatment of people of all races, income levels, and cultures with respect to the development, implementation and enforcement of environmental laws, regulations and policies.”³

1.4.2.1 CEQA Guidelines

Although the 2013 State of California CEQA Guidelines do not establish a requirement or a process for analyzing the environmental justice effects of projects subject to CEQA, in creating a new position within Cal/EPA, Assistant Secretary for Environmental Justice, the 2000-01 fiscal year budget established that the Assistant Secretary must:

*(a) Review the activities each [Board, Department or Office] within [Cal/EPA] undertakes to comply with Division 13 (commencing with section 21000) of the Public Resources Code [i.e., CEQA] to ensure that those activities take into account and address environmental justice considerations.*⁴

The California Attorney General has also recently stated that “[i]dentifying [disadvantaged and minority] communities is an essential part of describing the relevant CEQA setting” (State Attorney General, 2011).

³ California Code, Section 65040.12(c).

⁴ Stats. 2000, ch. 52, Item 0555-002-0001

The Attorney General has also stated in the context of pleadings (State Attorney General, 2012), that an EIR must:

- Disclose “information as to current levels of exposure by sensitive communities to the full range of... air pollution emissions,... [what] increases in potential exposure might be..., and what exposure levels will actually be.”
- Describe “environmentally related existing health conditions in these [sensitive] communities...”
- Disclose “the levels at which additional health damage can be expected...”
- “If the health of sensitive communities is already overburdened from existing air pollution and experiencing attendant harms to health, [consider whether] the additional pollution that the [proposed project] will cause... may produce significant harm in those communities.”

1.4.2.2 Senate Bill 115

SB 115 (Solis, 1998), among other things, requires the Cal/EPA to:

“[c]onduct its programs, policies, and activities that substantially affect human health or the environment in a manner that ensures the fair treatment of people of all races, cultures, and income levels, including minority populations and low-income populations of the state[;]” and “develop a model environmental justice mission statement for boards, departments, and offices within the agency.”

The Statute also requires Cal/EPA to ensure greater public participation in the agency’s development, adoption, and implementation of environmental regulations and policies.

1.4.2.3 Senate Bill 828

SB 828 (Alarcon, 2001) requires each board, department, and office within Cal/EPA to review its programs and identify gaps that may impede achievement of environmental justice by December 31, 2003.

1.4.2.4 Office of Environmental Health Hazard Assessment EnviroScreen Tool

In 2013, California's Office of Environmental Health Hazard Assessment (OEHHA) developed the *California Communities Environmental Health Screening Tool (EnviroScreen Tool)*. The *EnviroScreen Tool* uses existing environmental, health, demographic and socioeconomic data to assist Cal/EPA in fulfilling its environmental justice mission and to show “which portions of the state have higher pollution burdens and vulnerabilities than other areas, and therefore are most in need of assistance” (OEHHA, 2013).

The guidance document (OEHHA, 2013) accompanying the *EnviroScreen Tool*, issued by the Secretary of Cal/EPA, states that “[w]hile the data gathered in developing the tool could be useful for decision makers when assessing existing pollution sources in an area, more precise data are often available to local governments and would be more relevant in conducting such an examination.” The guidance document (OEHHA, 2013) also, notes that “EnviroScreen... cannot be used in lieu of performing an analysis of the potentially significant impacts of any specific project. Accordingly, a lead agency must determine independently whether a project's impacts may be significant under CEQA based on the evidence before it, using its own discretion and judgment.”

1.4.2.5 CARB Legal Memorandum

CARB has examined whether environmental justice may be evaluated under CEQA and received advice from legal counsel under a 2002 memorandum entitled “*CEQA and Environmental Justice*” (CARB, 2002c).

While CARB has noted that the memorandum does not necessarily reflect the current view of CARB, this memorandum states, in part,

For the reasons set forth below, we will conclude that CEQA can readily be adapted to the task of analyzing cumulative impacts/environmental justice whenever a public agency (including the CARB), the air pollution control districts, and general purpose land use agencies) undertakes or permits a Project or activity that may have a significant adverse impact on the physical environment. All public agencies in California are currently obliged to comply with the CEQA, and no further legislation would be needed to include an environmental justice analysis in the CEQA documents prepared for the discretionary actions public agencies undertake.

1.4.2.6 CARB Air Quality and Land Use Handbook

The *Air Quality and Land Use Handbook: A Community Health Perspective* (Handbook) (CARB, 2005a) advises air quality districts and local land use planning organizations on, among other things, how to reduce community exposure to air pollution through siting of oil refineries. With respect to refineries the Handbook recommends, “[a]void siting new sensitive land uses immediately downwind of petroleum refineries. Consult with local air districts and other local agencies to determine an appropriate suspension.”

1.4.2.7 Assembly Bill 32

Under AB 32 (Pavley & Nunez, 2006) CARB must consider environmental justice objectives when implementing the Global Warming Solutions Act. Section 38562(b)(2) requires that, to the extent feasible and in furtherance of reducing

statewide greenhouse gas emissions, CARB must ensure that compliance activities do not disproportionately impact low-income communities. Section 38570(b) further requires that, prior to implementation of a market-based system for greenhouse gas reduction compliance, CARB must consider the potential for direct, indirect, and cumulative emission impacts from these mechanisms, including localized impacts in communities that are already adversely impacted by air pollution. It must also design any market-based compliance mechanism to prevent any increase in the emissions of TACs or CAPs.

The design and implementation of market based systems for greenhouse gas reduction (i.e., the cap-and-trade program), including provisions addressing environmental justice, are under the jurisdiction of the CARB and not the City of Richmond.

1.4.3 Local Plans, Programs, and Regulations

1.4.3.1 BAAQMD CARE Program

As discussed above in Section 1.2.3.1, BAAQMD initiated the CARE program to evaluate and reduce health risks associated with exposures to outdoor TACs in the Bay Area. The program examines TAC emissions from point sources, area sources and on-road and off-road mobile sources co-located with sensitive populations to help focus mitigation strategies. Under the program, BAAQMD developed a preliminary Bay Area-wide TAC emissions inventory, compiled demographic and health-statistics data, and conducted regional computer modeling of selected TAC species to identify communities that are disproportionately impacted from high concentrations of TACs. As part of the CARE Program, BAAQMD developed a methodology for identifying communities within the San Francisco Bay Area that are likely to face the highest health risks from TACs, based on identifying areas that: (1) are close to or within areas of high TAC emissions; (2) have sensitive populations, defined as youth and seniors, with significant TAC exposures; and (3) have significant poverty. BAAQMD included the City of Richmond as one of six high priority communities, based on its analysis of conditions.

1.4.3.2 Contra Costa County Environmental Justice Policy

In 2003 the County of Contra Costa Board of Supervisors adopted the following policy on environmental justice:

Costa County will conduct its programs, policies and activities that substantially affect human health or the environment, and promote enforcement of all health and environmental statutes under County jurisdiction in a manner that ensures the fair treatment of people of all races,

cultures and income levels, including minority populations and low-income populations of the County.

The City of Richmond does not have jurisdiction over the decisions of the Contra Costa County.

APPENDIX 4.3 - SG

SG: Effect of API Gravity and Sulfur on Process Unit Operations

APPENDIX 4.3-SG

EFFECT OF API GRAVITY AND SULFUR ON PROCESS UNIT OPERATIONS

1.1 INTRODUCTION

The Chevron Refinery Modernization Project (Modernization Project) will increase the flexibility of the Facility to refine more higher sulfur crude and gas oil blends. As a result, the Facility may also process more crude oil blends at the heavier end of the intermediate American Petroleum Institute (API) gravity range than were processed during the Baseline. The increases in refining of these feedstocks may result in changes to Facility process unit operations (e.g., additional heating) and corresponding increases in air emissions. This appendix describes the data and methods used to evaluate whether processing of heavier crude oil blends within the intermediate gravity range or increased sulfur levels in crude oil blends requires additional heating in the crude unit furnaces or in the hydrotreater furnaces.

The emission sources considered in this evaluation include the following crude unit and hydrotreater furnaces:

- Crude unit pre-heater furnaces F-1100A and B (Sources S-4070 and S-4071);
- Crude unit vacuum column heater furnace F-1160 (Source S-4072);
- Diesel hydrotreater furnace F-1610 (Source S-4068);
- Naphtha hydrotreater furnaces F-447 and F-410 (Sources S-4061 and S-4062);
- Jet hydrotreater furnaces F-247 and F-210A&B (Sources S-4059 and S-4060);

1.2 DATA AND ANALYSIS METHODOLOGY

In order to evaluate the effect of gravity and sulfur in the crude oil blends on crude unit and hydrotreater furnace operations, a statistical analysis of feed rate, firing rate, gravity and sulfur weight percent (wt.%) data in the imported crude oil blends during the 2008 – 2010 period for the above listed crude unit and hydrotreater furnaces during the 2008 – 2010 period was undertaken. As part of this analysis, potential correlations between the ratio of feed rate to firing rate data and gravity and sulfur wt.% data were examined. Chevron provided the following data for analysis (Chevron Data Transmittal #1 (Rev #1), 2014; Chevron Data Transmittal #2, 2011).

- Feed rate to each furnace or furnace pair, in units of thousands of barrels per day (MBPD); daily-average data were received from Chevron, that were then averaged on a monthly basis to obtain monthly averages;
- Firing rate for each furnace, in units of million British Thermal Units per day (MMBTU/D); daily-average data were received from Chevron, that were then averaged on a monthly basis to obtain monthly averages;
- Sulfur wt.% in the imported crude oil blends - monthly average data was received, along with daily-average data for the 30 highest and 30 lowest sulfur content values over the 3-year period between 2008 and 2010; and
- Gravity of the imported crude oil blends - monthly average data was received, along with daily-average data for the 30 highest and 30 lowest gravity values over the 3-year period between 2008 and 2010.

For each of the five furnaces or furnace pairs associated with the emission sources listed above, the initial step in the relationship analysis was to determine the ratio of firing rate to feed rate for each data point.

To perform this statistical analysis, the ratio of firing rate to feed rate was plotted against both sulfur content (in wt.% sulfur) and gravity (in API) for each furnace or furnace pair. Note that for each plot, the sulfur wt.% or gravity values are the characteristics of the imported crude oil blends and not necessarily the characteristics of the feed entering each furnace or furnace pair. A statistical relationship was evaluated in this analysis using the Pearson Product-Moment Correlation approach. To be able to use this approach, the data need to generally meet the following conditions:

- The variables must be either interval or ratio measurements.^{1,2} All the plotted data are ratio measurements.
- The variables must be approximately normally distributed, which appears to be generally true for the crude oil data.
- There is a linear relationship between the two variables. The plotted data are generally linear.
- Outliers are kept to a minimum. In this analysis, sub-datasets are studied in order to test the hypothesis of whether outliers might be masking a

¹ A interval variable is a measurement where the difference between two values is meaningful. For example, the difference between a temperature of 100 degrees (°) and 90° is the same difference as between 90° and 80°.

² A ratio variable has all the properties of an interval variable and also has a clear definition of 0.0. When the variable equals 0.0, there is none of that variable.

correlation or whether correlations exist within narrower bands within the entire data set. All these results were accounted for in the statistical relationship determinations.

- There is homoscedasticity of the data, which is generally true for the crude oil data.

A coefficient of determination was generated for each plot shown below. The coefficient of determination, denoted as R^2 , ranges from 0 (0%) to 1 (100%), denotes the strength of the linear association between two variables or how well the data points fit in a predictive linear relationship. For example, an R^2 value of 0.4 means that 40% of the total variation of a firing rate to feed rate ratio can be explained by the linear relationship between the primary variable (e.g., sulfur content or gravity) and the firing rate to feed rate ratio. The other 60% of the firing rate to feed rate ratio variation remains unexplained by this relationship, which implies the linear relationship has a high level of uncertainty, and this relationship cannot be used to make predictions of reasonably likely conditions.

As discussed above, R^2 is correlation of determination which is a measure of linear dependence between two variables (Yale University, 1997).³ Although there is no hard rule for describing correlation strength, ENVIRON considered the following general guidelines in this analysis (Taylor, 1990; Gerstman, 2014; University of Strathclyde, 2014):

- $R^2 \leq 0.1$ to indicate no correlations,
- $0.1 < R^2 < 0.5$ to indicate weak correlations, and
- $R^2 \geq 0.5$ to indicate moderate to strong correlations.

In this analysis, the statistical relationship between two parameters was determined as no correlation, weak correlation, or moderate to strong correlation based on the R^2 value. A moderate to strong correlation indicates a likely relationship exists as more than 50% of the variation can be explained by the linear relationship and predicted trends made using the linear relationship are more likely than not to occur. Thus, moderate to strong correlations are certain enough to provide predictions of reasonable likely changes with the Modernization Project. As weak correlation has greater than 50% unexplained variation, the data confirm some relationship, but the uncertainty is high. If 10%

³ The coefficient of determination is the square of the correlation coefficient r (ranged from -1 to 0 to +1). A r value of 0 indicates that no linear relationship between the two variables, and a r of -1 or +1 indicates a perfect linear relationship. The positive and negative signs of r explain whether the two variables change in the same or opposite directions, respectively.

or less of the correlation is explained by the relationship, no predictions can be made based on the parameter tested.

The scatter plots generated from the data analysis are presented in Figures A4.3-SG-1 to A4.3-SG-20.

1.3 EFFECT OF API GRAVITY ON PROCESS UNIT OPERATIONS

The acceptance of crude oil blends at the heavier end of the intermediate gravity range could require higher levels of processing (e.g., more heat) from certain operating units at the Facility and may require additional energy for pumping the crude oil. For example, additional heat could be required to heat, and then distill into various fractions, a heavier crude oil blend in the crude unit.

In order to evaluate the potential for the additional heating required to process heavier crude oil blends within the intermediate gravity range, Chevron provided data from 2008 – 2010 on heating rates as a function of imported crude oil gravity for various emission sources.

As shown in Figures A4.3-SG-1 through A4.3-SG-10, the effect of imported crude oil gravity on firing rates for various emission sources was variable across the five furnaces evaluated. The calculated R^2 values for monthly average data ranged from 0.02 (S-4070, S-4071) to 0.44 (S-4072), while for daily average data the R^2 values ranged from 0.03 (S-4058) to 0.64 (S-4072, S-4062). These calculated R^2 values indicate that the statistical relationship between crude blend gravity and firing/feed ratio is weak to moderate and varies from source to source. Thus, increases in the ratio of firing rate to feed rate are not reasonably likely to occur with heavier gravity crude oils expected with the Modernization Project given the lack of a strong correlation and variability among sources.

Nonetheless, this represents an uncertainty in the analysis as the imported crude oil gravity from 2008 - 2010 did not vary substantially.

1.4 EFFECT OF SULFUR ON PROCESS UNIT OPERATIONS

This analysis aims to provide a better understanding of whether more heat or other energy will be required to process increased sulfur levels in the imported crude oil and gas oil blends. Hydrotreating, which is the process of removing sulfur from the fuel oil by combining it with hydrogen, is an exothermic process (i.e., the process generates heat through the chemical reaction of sulfur with hydrogen) (EPA, 2000; Schuit et al., 1973). Because it is an exothermic process (i.e., heat would be generated by the reaction), it is unlikely that additional sulfur will require higher firing rates (i.e., additional external heat energy) in the hydrotreating units, because additional heat is generated by the reaction, which can displace heat required from furnaces.

The 2008-2010 data were analyzed for a range of imported crude oil sulfur values. As is shown in Figures A4.3-SG-11 through A4.3-SG-20, the effect of sulfur on the firing rates for the different furnaces was variable, and shows uncertainty, but no clear trends. In more than half the cases, the energy required appeared to decrease with increasing sulfur, and in the other cases, the energy required appeared to increase with increasing sulfur. The calculated R^2 values for monthly average data ranged from 0.00003 (S-4072, S-4062) to 0.12 (S-4068), while for daily average data the R^2 values ranged from 0.02 (S-4059) to 0.52 (S-4068). These calculated R^2 values indicate that the relationship between the sulfur wt.% and firing/feed ratio is weak to moderate in strength, but that the direction of the variation is inconsistent. Thus, increases in the ratio of firing rate to feed rate are not reasonably likely to occur with increasing sulfur content crude oils expected with the Modernization Project given the lack of a strong correlation and variability among sources.

However, it is noted that the range of sulfur in the 2008-2010 data may not be sufficiently wide to show the variation that might be expected during the Modernization Project, as imported crude oil blends' sulfur wt.% is expected to increase above that from 2008 - 2010.

APPENDIX 4.3 - SHP

SHP: Shipping CAP, TAC, and GHG Emissions

APPENDIX 4.3-SHP

SHIPPING CAP, TAC, AND GHG EMISSIONS

This appendix outlines the methods, data, and assumptions used to estimate criteria air pollutant (CAP), toxic air contaminant (TAC), and greenhouse gas (GHG) emissions from shipping activities associated with the Modernization Project. Emissions associated with rail and on-road truck activity are discussed in *Appendix 4.3-TRANS*. Operational Refinery emissions are discussed in *Appendix 4.3-OP*. Emissions associated with construction are considered in *Appendix 4.3-CST*.

A summary discussion of shipping is presented here and is also in *Chapter 3, Project Description* of this EIR. A full description of the methods, data and assumptions used to estimate CAP, TAC and GHG emissions from shipping activities associated with the Modernization Project can be found in a report prepared by Chevron's contractor, ICF International (Chevron Data Transmittal #26F, 2014). The ICF International report fully documents all shipping emission estimates that were used to assess Air impacts for the EIR. The principal investigator for ICF International is Dr. Lou Browning who has prepared a number of shipping emission analyses including the report "Current Methodologies in Preparing Mobile Source Port-Related Emission Inventories" (ICF, 2009) which was prepared for the U.S. Environmental Protection Agency.

The Facility imports crude oil, gas oil and some blendstocks and exports a portion of its refined products and some gas oil, blendstocks, and baseoils via ships and barges. This waterborne transport includes self-propelled ocean going vessels (OGVs – i.e., tanker ships) and vessels that are not self-propelled (i.e., barges) that dock at the Long Wharf and either unload and/or load liquid materials over the dock. Both the OGVs and barges require assistance from smaller ships called tugs (also called harbor craft). The OGVs, barges, and tugs utilize engines fueled by fossil fuels to perform their operations; thus emit CAP, TAC and GHG airborne emissions as part of their routine operation at the Long Wharf. Import and export volume is the primary activity that influences vessel activity (i.e. vessel calls to the Long Wharf).

Shipping emissions were developed for vessels calling the Long Wharf for the three scenarios listed below:

1. 2008-2010 period (Chevron Data Transmittal #47A (Rev #6), 2014): Shipping emission estimates based on baseline shipping activity (i.e. import and

export volumes and vessel calls) and regulations in the historical 2008 to 2010 time period.

2. Baseline Period (Chevron Data Transmittal #47A (Rev #6), 2014): Shipping emission estimates based on baseline shipping activity in the historical 2008 to 2010 time period with a fleet of 2016 vessels adhering to 2016 regulatory requirements.
3. Project Case (Chevron Data Transmittal #26F, 2014): Shipping emission estimates based on estimates of project shipping activity and regulations as of 2016 with a fleet of 2016 vessels adhering to 2016 regulatory requirements.

Table A4.3-SHP-1 presents the shipping vessel types, their emission sources, and describes the types of CAP and TAC emissions. All vessel types also emit GHGs.

TABLE A4.3-SHP-1 SUMMARY OF SHIPPING EMISSION SOURCES

Vessel Type	Emission Source	Criteria Air Pollutants Emitted with CEQA Mass Thresholds	Toxic Air Contaminants Emitted
OGVs	Propulsion Engine(s) Auxiliary Engine(s)	NO _x , PM ₁₀ ^a , PM _{2.5} , ROG	DPM ¹
	Boiler	NO _x , PM ₁₀ , PM _{2.5} , ROG	ROG, PM
Barges	Auxiliary Engines	NO _x , PM ₁₀ ¹ , PM _{2.5} , ROG	DPM ¹
Tugboats	Propulsion Engine(s) Auxiliary Engine(s)	NO _x , PM ₁₀ ¹ , PM _{2.5} , ROG	DPM ¹

^a For internal combustion, diesel engine emission sources, emissions of DPM, which is included as a toxic air contaminant, are assumed to be equivalent to emissions of PM₁₀, which are included as a criteria pollutant.

The methods used in the inventory are consistent with the design of other San Francisco Bay shipping emission inventories (ENVIRON, 2008; M&N and ENVIRON, 2010a,b,c,d) with some exceptions associated with Modernization Project-specific aspects, CEQA considerations, and Department of Homeland Security considerations as explained in *Chapter 3, Project Description*, of this EIR and ICF (Chevron Data Transmittal #26F, 2014)

The shipping emissions Baseline presented in this EIR differs from typical shipping emission inventories in the use of data from Chevron's proprietary Stock Transfer and Reconciliation (STAR) database which tracks activity at the Long Wharf including load and discharge times and volumes as well as time at-berth for each vessel call. The STAR database was used to estimate time at-berth and

volume and time of transfer by product for pumping. The STAR database is the only data source for this Chevron-specific data. The average time at berth provided by Chevron is consistent with public information available from the San Francisco Marine Exchange.

To avoid disclosure of shipping call data withheld in compliance with the United States Department of Homeland Security, this analysis employed averaged parameter values by ship, propulsion, and pump type. Call-specific parameter values are not reported. This means that certain inputs (e.g., main and auxiliary engine horsepower (HP), vessel service speed, ship capacity, pump capacity) are averaged values based on ship type, propulsion type, and pump type for the ship and barge calls made at the Long Wharf during the Baseline.

Total crude and gas oil volumes for the Modernization Project were estimated using the Unit Rate Model, as described in *Appendix 4.3-URM*. The feedstock volumes are dependent on the crude blend and Refinery Operations utilization rate. The product volumes for a given future scenario are estimated assuming the same volumetric ratio of product to feedstocks (ratio of 1.04) as during the baseline. The amounts of cutter and light product discharged tend to vary year-to-year and are not related to Refinery Operations utilization. These amounts are estimated to increase for future cases, relative to the Baseline; therefore, the Modernization Project assumes an increase over baseline in cutter and light product discharges. For the Modernization Project, two Refinery Operations utilization rates using Basrah + Arab Lt crude blend were considered: 93 percent and 100 percent.

Shipping emissions are not subject to CEMs monitoring, were not included in the BAAQMD Engineering Evaluation, and are not included in the BAAQMD Emission Inventory.

CAP and GHG emissions from shipping activities are estimated from the previous port of call to the Long Wharf and from the Long Wharf to the next port of call. Outside of San Francisco Bay, the shipping emissions account for emissions to and from the Pilot Buoy, located approximately 8 nautical miles west of Point Bonita near the entrance of the San Francisco Bay, to the entrance of the San Francisco Bay as determined in discussions with the BAAQMD. Shipping CAP and GHG emissions for the 2008-2010 baseline period and Project Crude Blend and the Lightest/Max Shipping Crude Blend cases are presented in Table A4.3-SHP-2.

TAC emissions were estimated for any shipping activity that occurs within the HRA boundary (i.e., within 5 nautical miles of the Long Wharf). The TAC emissions inventory includes chemicals emitted from sources that are included

TABLE A4.3-SHP-2 SHIPPING BASELINE AND MODERNIZATION PROJECT CAP AND GHG EMISSIONS, WITH PDFs

Emissions Case	Emissions (tons/year)						GHGs (Tonnes CO ₂ e/year)	Change from Baseline (tons/year)						GHGs (Tonnes CO ₂ e/year)

Note: carbon monoxide (CO), nitrogen oxides (NO_x), particulate matter (PM₁₀ & PM_{2.5}), sulfur dioxide (SO₂), volatile organic compounds (VOCs).

for consideration in HRAs consistent with BAAQMD Regulation 2, Rule 5. The TAC emissions inventory for shipping is based on diesel particulate matter (DPM)

emissions from internal combustion propulsion and auxiliary engines and on PM_{10} and reactive organic compounds (ROGs) for boilers. The PM_{10} emissions from internal combustion propulsion and auxiliary engines were assumed to be equivalent to DPM in the emissions estimation. TACs associated with boiler combustion are evaluated by speciating ROG emissions (i.e., dividing total ROG into individual TAC compounds that are in ROG) according to California Air Resources Board (CARB) emissions profile #504, and PM emissions according to EPA emissions profiles #5676 and #127102.5, based on consultation with and direction from the BAAQMD. Shipping TAC emissions for the 2008-2010 baseline period and Project Crude Blend and the Lightest/Max Shipping Crude blend cases are presented in Table A4.3-SHP-3. For air dispersion modeling, emissions need to be spatially allocated based on where and how they will be emitted. More details on emissions apportionment is provided in *Appendix 4.3-HRA*.

1.1 SHIPPING EMISSIONS QUALITY ASSURANCE

ENVIRON reviewed the shipping emissions estimation methodology described in the ICF report and shipping emission estimates (Chevron Data Transmittal #47A (Rev #6), 2014; Chevron Data Transmittal #26F, 2014). ENVIRON took the following steps to evaluate the emission inventory:

- Confirmed that applied emission factors are consistent with CARB estimates (CARB, 2010; CARB, 2011) for all diesel-fueled engines. Confirmed that applied boiler emission factors are consistent with boiler emission rates by fuel-type in the 2011 Port of Los Angeles emission inventory (Starcrest, 2013).
- Confirmed that vessel transit speeds in the San Francisco Bay are reasonably consistent with estimates in M&N and ENVIRON (2010a,b,c,d).
- Compared vessel horsepower and service speed estimates to other studies (Table A4.3-SHP-4). Comparisons indicate that Long Wharf estimates are reasonably consistent with other studies.
- Confirmed that applied engine load factors are consistent with other studies.
 - In-transit OGV propulsion engine load-factors were estimated based on the propeller law consistent with load factor estimates for other OGV inventories.
 - OGV auxiliary engine load factors are consistent with a 2010 Port of Long Beach inventory (Starcrest, 2011).

Notes: SSD = slow speed diesel engine, MSD = medium speed diesel engine, MSD-ED = medium speed diesel engine driving an electric generator, RLW = Richmond Long Wharf, kWh = kilowatt, POLA = Port of Los Angeles.

^a Port of Los Angeles, 2014.

^b Starcrest, 2013.

- Tug and barge engine load factors are consistent with estimates used in the 2011 Port of Los Angeles emission inventory (Starcrest, 2013).
- Confirmed that applied low load adjustment factors are consistent with the 2011 Port of Los Angeles emission inventory (Starcrest, 2013).
- Confirmed that OGV boiler loads were estimated based on the best available information.
 - Boiler load estimates for maneuvering, low speed transit and anchorage are consistent with tanker boiler load of 371 kilowatts based on 2011 Port of Los Angeles (POLA) emission inventory (Starcrest, 2013).
 - Boiler load estimates for at-berth unloading pumping were estimated based on pumping energy calculations from first principles.
- Confirmed that vessel calls were consistent with the ratio of total import volumes to average parcel size.

ENVIRON also performed the calculations described below to assure the accuracy of the inventory:

- Emissions, time-in-mode, horsepower, and load factors were used to back calculate emission factors which were confirmed to be consistent with the applied emission factors.
- 40-year and 70-year emission factors were compared to the base year emission factors to assure that these 40-year and 70-year estimates correctly accounted for future changes to vessel fleets (e.g. turnover to new tug engines in compliance with CARB Harbor Craft replacement requirements in 17 CCR Section 93118.5) and fuel regulations (e.g. OGV fuel sulfur content requirements per CARB regulations in 13 CCR Section 2299.2).

ENVIRON also reviewed third party sources of information to confirm maneuvering time and berthing time information provided by Chevron in the ICF report.

ICF estimated a maneuvering time of 40 minutes one-way for each OGV to maneuver into and out of a berth (Chevron Data Transmittal #26F, 2014). ENVIRON obtained Automatic Identification System (AIS) ship position data for the 2009 to 2010 period (36 maneuvering events analyzed) and 2013 data (14 maneuvering events analyzed). AIS data, therefore, cannot be used to precisely determine maneuvering end or start time because the main engine can remain running or have started when the ship is stationary at or near the berth. The maneuvering time determined from the AIS data underestimates the total time the main propulsion engine is operating because the engine will operate after

reaching the berth or before leaving the berth. Based on the AIS data, ENVIRON estimated an average maneuvering time of 30 minutes for the 2009 to 2010 calls and 23 minutes for the 2013 calls. The ICF estimate of 40 minutes of maneuvering time one-way, is reasonably consistent with the results ENVIRON compiled from the AIS data.

ICF includes estimates of vessel time-at-berth which can be combined into a call weighted average time-at-berth of 40 hours per call across all vessel calls (ICF, 2014). ENVIRON analyzed Richmond Long Wharf call data for 2008 to 2010 from the Marine Exchange of the San Francisco Bay Region and estimated average at-berth time for a limited number of calls. Data for 538 OGV calls to the Long Wharf allowed for direct estimation of at-berth time based on time stamps for arrival to and departure from the Richmond Long Wharf. For 163 calls, times of arrival to and departure from the Long Wharf were not available; for these calls departure and arrival times were able to be estimated based on Golden Gate Bridge time stamps adjusted for the average transit time between the Golden Gate and the Richmond Long Wharf. Consistent with ICF (2014), average time at-berth was estimated to be 40 hours for the 701 total calls analyzed.

APPENDIX 4.3 - TRANS

Trans: Rail and Truck Emissions

APPENDIX 4.3

TRANS: RAIL AND TRUCK EMISSIONS

This appendix describes the methods used to estimate emissions from rail and truck transportation to and from the Facility. Emissions estimation methods are contained for the Baseline and the Modernization Project.

The 2008 – 2010 emissions were adjusted to reflect what the emissions associated with activities would be if they took place in 2016. Therefore the fuel consumption for the Baseline is identical to 2008 – 2010 but the emission factors correspond to the 2016 operations. For the Modernization Project, the fuel consumption is scaled from the 2008 – 2010 emissions based on the transportation activities.

Both rail and trucking operations emit particulate matter <10 microns (PM_{10}) and particulate matter < 2.5 microns ($PM_{2.5}$). For the purposes of this EIR, for rail, $PM_{2.5}$ is conservatively assumed to be equal to PM_{10} . Therefore, throughout the rail section of this appendix, reference will be made to $PM_{10}/PM_{2.5}$. PM_{10} and $PM_{2.5}$ emissions were estimated separately for trucking.

4.1 RAIL EMISSIONS

This section explains the emissions calculation methodology for rail transportation associated with Facility operations for the 2008-2010 period, Baseline, and the Modernization Project. The rail emissions are calculated based on the fuel consumption and United States Environmental Protection Agency (EPA) locomotive emission factors (EPA, 2009), and the methodology is identical for the Baseline and Modernization Project. This section details the emissions calculation for all aspects of rail operations, including switching inside the Facility fenceline, switching at the BNSF railyard, and line haul. In addition, the potential for volatile emissions during rail transport is also addressed.

4.1.1 Chevron Rail Operations

Certain materials are transported by rail to and from the Project site. Materials transported by rail include liquefied petroleum gases, lubricant base oils, lubricants, lubricant additives, and ammonia. During the 2008-2010 period and years since, the Facility did not receive gas oils or crude oil by rail. Chevron has also attested that it will not receive gas oils or crude oil by rail as a result of the Modernization Project (Chevron Data Transmittal #36G (Rev #1), 2013).

4.1.2 Source Identification

Criteria air pollutants (CAPs), toxic air contaminants (TACs), and greenhouse gases may be emitted as a result of the following rail activities associated with Facility operations:

- Volatilization of constituents carried in rail cars via railcar dome openings (i.e., vent and safety valves for maintaining a stable pressure) and loading emissions;
- Engine exhaust resulting from switching operations within the Facility fenceline;
- Engine exhaust resulting from switching operations at the BNSF railyard outside the Facility fenceline; and
- Engine exhaust resulting from line haul operations (i.e., rail transportation between the adjacent railyards and other major rail terminals within the Bay Area Air Quality Management District [BAAQMD] jurisdiction boundary). As discussed later in this section, the longest possible rail route within the BAAQMD jurisdiction boundary was used for the emissions calculation.

Railcar dome openings and loading emissions associated with the transportation of lubricants and lubricant-related materials from railcars are negligible because the typical vapor pressure of these materials is less than 0.02 pounds per square inch absolute (psia) (BAAQMD, 2006). Materials with low vapor pressure, such as lubricants, have low volatility and are less likely to vaporize and generate evaporative emissions. Railcars that carry pressurized materials, such as LPG and ammonia, do not have railcar dome openings. Therefore, loading emissions associated with the transportation of LPG and ammonia from pressurized railcars are negligible because they operate under a closed system with vapor return back to LPG spheres, ammonia bullets, or other process vessels.

4.1.3 General Methodology and Equation for Rail Emissions Calculation

The locomotives of switchers and line haul trains are both fueled with diesel fuel, and CAPs, TACs, and greenhouse gases are emitted as a result of diesel fuel combustion in the engines. CAPs include carbon monoxide (CO), volatile organic compounds (VOCs), nitrogen oxides (NO_x), sulfur dioxide (SO_2), and $\text{PM}_{10}/\text{PM}_{2.5}$. As discussed below, diesel particulate matter (DPM) is the only TAC considered here that is emitted from the combustion of diesel fuel. Finally, the emitted greenhouse gases include carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O). Emissions from diesel combustion are calculated based on the fuel consumption using the following general formula:

$$E_i = EF_i \times FC \times K$$

Where:

E_i : emissions of constituent i in tons/year for CAP and TAC and in metric tonnes/year for greenhouse gas

EF_i : emission factor of constituent i in grams per gallon (g/gal) of diesel

FC = Fuel Consumption: in gallons/year

K: unit conversion from grams to tons or metric tonnes

4.1.4 TAC Emissions from Railway Exhaust

Diesel exhaust is a complex mixture that includes hundreds of individual constituents (Cal/EPA, OEHHA, 1998), and it is identified by the State of California as a known carcinogen (Cal/EPA, CARB, 2011). Under California regulatory guidelines, DPM is used as a surrogate measure of carcinogen exposure for the mixture of chemicals that make up diesel exhaust as a whole (Cal/EPA, CARB, 2011). Cal/EPA and other proponents of using the surrogate approach to quantifying cancer risks associated with the diesel mixture indicate that this method is preferable to use of a component-based approach. A component-based approach involves estimating risks for each of the individual components of a mixture. Critics of the component-based approach believe it will underestimate the risks associated with diesel as a whole mixture because the identity of all chemicals in the mixture may not be known and/or exposure and health effects information for all chemicals identified within the mixture may not be available. Furthermore, Cal/EPA has concluded that “potential cancer risk from inhalation exposure to whole diesel exhaust will outweigh the multi-pathway cancer risk from the speciated components” (Cal/EPA, OEHHA, 2003). In this section, the emissions of DPM are assumed to be the same as the emissions of $PM_{10}/PM_{2.5}$ in diesel exhaust and are not calculated separately.

4.1.5 2008 – 2010

Emissions during 2008 – 2010 are based on activity data (number of railcars coming to and leaving from the Project site) and emissions factors. This is further described below.

4.1.5.1 Activity Data

During 2008 – 2010, the Facility accepted 227,900 barrels of crude oil and 48,000 barrels of gas oil per day as shown in Table A4.3-TRANS-1. Though the

crude oil and gas oil are not transported by rail, the Facility throughput directly affects the quantities of material needed (i.e., LPG and additives) and produced (i.e., LPG, lubes, and ammonia) that are transported to and from the Facility by rail.

As shown in Table A4.3-TRANS-1, the Facility received 2,034 railcars of LPG and 279 railcars of additives averaged annually during 2008 – 2010. The Facility also exported 1,485 railcars of LPG, 1,445 railcars of lubricant, and 112 railcars of ammonia averaged annually during 2008 - 2010. As presented later in Table A4.3-TRANS-7, a railcar can carry 64 tons of liquefied LPG or ammonia and 77 tons of lubricants or lubricants-related material (e.g., additives) (Chevron Data Transmittal #36G (Rev #1), 2013). This results in an average of 5,243 loaded railcars that were needed for material input and product deliveries per year during 2008 - 2010.

4.1.6 Emissions Calculation for Switching inside the Fenceline

A switcher is a small locomotive used for assembling a train for a line haul locomotive or for disassembling a train that has been brought in. A switcher usually moves railcars around within a railyard and is not intended for moving trains over a long distance. The switchers inside the Facility fenceline are owned by Chevron and only serve the trains going to and from the Project site.

4.1.6.1 Emission Factors

CO, total hydrocarbons (HC), NO_x, and PM₁₀/PM_{2.5} (or DPM) emissions associated with the switchers are calculated based on EPA's fuel-based emission factors (EPA, 2009). Note that HCs, or total hydrocarbons, is converted to VOCs using the EPA's conversion factor (EPA, 2005). For locomotives manufactured after 1973, the EPA's locomotive engine Tier standards described in 40 CFR Part 92 and 1033 apply based on the year in which the locomotive was originally manufactured. For pre-1973 locomotives, to which the Tier standards do not apply, the uncontrolled emission factors are selected.

The switcher trains operated by the Facility inside the Facility fenceline were originally manufactured in the 1960s, and therefore the Tier standards do not apply. In this calculation, the EPA's uncontrolled switcher emission factors are used as presented in Table A4.3-TRANS-2.

The SO₂ emission factor is calculated based on the regulatory diesel sulfur content of 15 parts per million (EPA, 2012), assuming 100% of the sulfur in diesel is converted to SO₂. The detailed calculation is explained in Table A4.3-TRANS-2.

Greenhouse gas emissions from diesel combustions include CO₂, CH₄ and N₂O. The units CO₂ and greenhouse gas (or CO₂e) are used interchangeably for diesel engine emissions because CH₄ and N₂O are assumed to contribute a negligible amount of global warming potential (GWP) when compared to the CO₂ emissions (CCAR, 2009). The fuel based CO₂ emission factor is calculated by converting EPA's heat input-based emission factor in kilogram (kg) per million British thermal units (MMBtu) to kg per gallon (kg/gal) of diesel used using the diesel high heating value (HHV) in MMBtu/gal (EPA, 2011). The details are explained in Table A4.3-TRANS-2.

4.1.6.2 Fuel Consumption

The fuel consumption for the switching activity for 2008 – 2010 was provided directly by the Facility (Chevron Data Transmittal #36G (Rev #1), 2013). The switcher consumed an average of 32,689 gallons diesel per year during 2008 – 2010 as presented in Table A4.3-TRANS-3.

4.1.6.3 Emissions

As shown in Table A4.3-TRANS-3, the switching inside the fenceline during 2008 – 2010 generated 1.0 ton of CO, 0.6 tons of VOC, 9.5 tons of NO_x, 0.003 tons of SO_x, and 0.2 tons of PM₁₀/PM_{2.5} and DPM, and 334 metric tons of CO₂ per year.

4.1.7 Switching at the BNSF Railyard

Switching activities also occur in the BNSF railyard outside the Facility fenceline. The switchers in the BNSF railyard are owned by BNSF and serve both Chevron trains and non-Chevron trains. The BNSF railyard activities were used to estimate the off-site switching emissions.¹

4.1.7.1 Emission Factor

The BNSF switch engines at the BNSF railyard are also assumed to be 100% uncontrolled given that there was no information provided on the BNSF fleet. The emission factors for switching at the BNSF railyard are same as those for switching inside the fenceline summarized in Table A4.3-TRANS-2.

4.1.7.2 Fuel Consumption

The BNSF railyard serves a number of locations, including the Facility. Only a fraction of the switching activities at the BNSF railyard are Facility related. The

¹ In order to simplify the analysis and due to limited availability of data, switching operations data from BNSF were used to determine emissions for all switchers outside of the fenceline that service Chevron's railcars (even though Union Pacific also has switchers that service Chevron's rail cars).

fuel consumption for switching at the BNSF railyard that is associated with the Facility was scaled from the total switching diesel usage at the BNSF railyard using the ratio of the number of locomotives to and from the Facility from the BNSF railyard.

The BNSF switch fuel usage is estimated based on the total switch operational time provided in the Richmond Railyard TAC Emissions Inventory (ENVIRON, 2006) and switcher fuel consumption rate provided in the Port of Oakland Seaport Air Emissions Inventory (ENVIRON, 2008). The detailed calculation is presented in Table A4.3-TRANS-4. Based on information provided in these reports, 186,159 gallons of diesel fuel were used at the BNSF railyard for switching.

The number of locomotives to and from the Facility is estimated based on the total number of railcars that served the Facility, as discussed previously, number of railcars per unit train, and number of locomotives per unit train.² A unit train is a freight train moving a large tonnage of single bulk products between two terminals. Unloaded upon arrival and returned promptly for another load, the unit train is more cost efficient because it eliminates intermediate yarding and switching. The detailed calculation presented in Table A4.3-TRANS-5 conservatively assumes that all trains are loaded and unloaded at the BNSF railyard, the trains that transport the input materials leave the Facility empty, and trains that transport products arrive at the Facility empty. This assumption maximizes the number of locomotive trips as well as the switching services associated with the Facility. As shown in Table A4.3-TRANS-5, the Facility operation needs 655 locomotive trips per year at the BNSF railyard for transporting input material and delivering products. A total of approximately 10,725 locomotives arrive and depart the BNSF railyard based on the Richmond Railyard TAC Emissions Inventory.

Approximately 11,376 gallons of fuel per year were consumed by switching at the BNSF railyard associated with the Facility operations during 2008 – 2010 as shown in Table A4.3-TRANS-5.

4.1.7.3 Emissions

As shown in Table A4.3-TRANS-5, switching at the BNSF railyard during 2008 – 2010 generated 0.3 tons of CO, 0.2 tons of VOC, 3.3 tons of NO_x, 0.001 tons of SO₂, and 0.07 tons of PM₁₀/PM_{2.5} and DPM, and 116 metric tons of CO₂ per year.

² The number of railcars, buffer cars, and locomotives per unit train are from Chevron Transmittal #36G (Rev #1), Attachment 2, 2013.

4.1.8 Line Haul

Line haul refers to the transportation of materials or products over long distances (e.g., between two major cities or terminals).

4.1.8.1 Emission Factor

The fuel consumption based line haul NO_x , HC, and $\text{PM}_{10}/\text{PM}_{2.5}$ emission factors for 2008 – 2010 is the average of 2008, 2009, and 2010 EPA emission factors (EPA, 2009). The CO emission factor is a constant for all Tiers so it does not vary by year. The SO_2 and CO_2 emission factors are calculated following the same methodology as for the switching activities. The emission factors are summarized in Table A4.3-TRANS-6.

4.1.8.2 Fuel Consumption

The fuel consumption associated with LPG receipts, additive receipts, LPG and ammonia shipments, and lubricant shipments is estimated separately based on the annual gross ton-mile (GTM) and average fuel efficiency of the train.

GTM is a common unit used in rail transportation, and it is the product of total weight (including the weight of locomotives, railcars, and buffer cars)³ and the distance traveled by a train. For the trains arriving loaded and departing empty, the inbound annual total weight include the weight of the materials (e.g., additives), locomotives, railcars, and buffer cars. Each incoming train (loaded) consists of 6 locomotives, 96 railcars, and 4 buffer cars (Chevron Data Transmittal #36G (Rev #1), Attachment 2, 2013). The unit weight of each component of the train as well as for the material in a railcar is listed in Table A4.3-TRANS-7. The outbound train has the same number of railcars and buffer cars but only three locomotives.¹⁵ In addition, the railcars of an outbound train are empty so the weight of the material is excluded. Similarly, for the trains arriving empty and departing loaded, the outbound train includes the product, 6 locomotives, 96 railcars, and 4 buffer cars, and the inbound train consists of 3 locomotives and the same number of railcars and buffer cars but no product. The total inbound and outbound annual gross weights are estimated based on the materials transported by rail to and from the Facility, as summarized in Table A4.3-TRANS-7.

The GTM is then calculated by multiplying the gross weight by the traveled distance. To be conservative, the one-way trip distance of 65 miles (the longest

³ Buffer cars are to be placed between the locomotive engine and shipments as required by federal regulations for safety purposes (e.g., to isolate explosives from ignition sources and from the train crew).

rail distance from the Project site to the boundary of the BAAQMD [i.e., from the Project site to Davis, CA] by rail) was used (BNSF, 2013).

The average fuel efficiency of 955 GTM/gal is estimated by dividing the total GTM by the total diesel consumption reported in the BNSF Railway Class I Railroad Annual Report Restatement.⁴ The fuel consumption associated with the line haul portion of rail transport of material to and from the Facility is calculated by dividing the total GTM by the average fuel efficiency. The line haul activities are estimated to consume 58,887 gallons of fuel per year during 2008 – 2010.

4.1.8.3 Emissions

As shown in Table A4.3-TRANS-7, the line haul activities during 2008 – 2010 generated 1.7 tons of CO, 0.6 ton of VOC, 10.6 tons of NO_x, 0.006 tons of SO₂, and 0.3 tons of PM₁₀/PM_{2.5} and DPM, and 601 metric tons of CO₂ per year.

4.1.9 Emissions Summary

Table A4.3-TRANS-8 summarizes the CAP, greenhouse gas, and TAC emissions from switching inside fenceline, switching at the BNSF railyard, and line haul during 2008 – 2010. The 2008 – 2010 rail activities emitted 3.1 tons of CO, 1.4 tons of VOC, 23.5 tons of NO_x, 0.01 tons of SO₂, and 0.6 tons of PM₁₀/PM_{2.5} and DPM, and 1,051 metric tons of CO₂ per year.

4.1.10 Baseline

The 2008 – 2010 emissions were adjusted to reflect what the emissions associated with activities would be if they took place in 2016. As discussed below, the only adjustment made to the 2008 – 2010 rail emission is to substitute in the 2016 line haul emission factors for long distance locomotives as approved by EPA. No adjustments are made to emission factors for localized switching locomotives. Changes to line haul emission factors from 2008 – 2010 to the Baseline result in an overall reduction in emissions of both CAPs and TACs.

EPA's locomotive engine tier standards described in 40 CFR Part 92 and 1033 are not applicable to the switching engines inside the fenceline. The same is true for switching engines in the BNSF railyard. There is no information from either

⁴ A Class I Railroad Annual Report (usually called R1 report) is required for every class I railroad operating within the United States. The reported figures need to be an accurate and honest assessment of the railroads activity. The national fuel efficiency in the BNSF R1 report undergoes strict accounting practices. While not specific to California, the estimates include in-yard, maintenance, and line-haul activity in California. No other public data source has undergone the level of review as the fuel efficiency reported in the R1 report.

BNSF or Chevron indicating that they are upgrading their switching fleets between now and 2016. Accordingly, 2008 – 2010 emission factors will be used for the CAP, greenhouse gas, and TAC emissions from switching both within the Project site and at the BNSF railyard. Therefore, the CAP, greenhouse gas, and TAC emissions from switching at the Facility and at the BNSF railyard are identical to those during 2008 – 2010 (Tables A4.3-TRANS-2 to -5).

The line haul emissions are calculated following the same methodology as 2008 – 2010 but using the EPA's 2016 fleet average emission factor (Tables A4.3-TRANS-6 and -7).

4.1.11 Total Baseline Emissions Summary

The total rail emissions for the Baseline are summarized in Table A4.3-TRANS-8. The overall rail activities in this scenario emit 3.1 tons of CO, 1.1 tons of VOC, 20.7 tons of NO_x, 0.01 tons of SO₂, 0.5 tons of PM₁₀/PM_{2.5} and DPM, and 1,051 metric tons of CO₂ per year. Compared to the actual emissions during 2008 – 2010, the VOC, NO_x, and PM₁₀/PM_{2.5} (DPM) emissions are lower due to more stringent emission standard. CO, SO₂, and CO₂ emission factors are not affected by the 2016 standard, so the emissions for those pollutants are the same as the actual emissions during 2008 – 2010.

4.1.12 Project Emissions

There are three categories of change to the Baseline that must be evaluated in estimating Modernization Project emissions. The first is the physical changes to Facility equipment that result in new or different emissions. The second is the increase in emissions that would result from the change from the Baseline utilization to a reasonably foreseeable utilization. The third is the change in emissions that would result from the processing of higher sulfur crude oils and crude oils at the lower and higher ends of the intermediate-light gravity range. The third category of change does not impact rail emissions, as it does not change the volumes or types of materials shipped by rail, as the Facility does not receive feedstock, nor ship product by rail.

Emissions associated with a Modernization Project scenario are calculated based on the emission factors of the Modernization Project's commencement year of 2016, which are identical to those of the Baseline. Since the fuel consumption is directly related to the rail activity, the emissions as well as the fuel consumption for the Modernization Project are scaled from the Baseline based on the rail activity.

4.1.13 Activity Data

Table A4.3-TRANS-1 summarizes the rail activity data including the Facility crude oil and gas oil throughput, number of railcars of LPG and additive received, and number of railcars of lubricant, ammonia, and LPG delivered for various Modernization Project scenarios.

4.1.14 Switching Inside the Fenceline

As discussed earlier, the emission factors for the switching engine are uncontrolled and do not vary by year. The fuel consumption as well as the CAP, TAC, and greenhouse gas emissions of a Modernization Project scenario are scaled from those of the Baseline based on the ratio of the total crude and gas oil throughput. Table A4.3-TRANS-3 summarizes the scaled emissions associated with switching inside the Facility fenceline for various Modernization Project scenarios.

4.1.15 Switching at the BNSF Railyard

As discussed earlier, the emission factors for the switching engine are uncontrolled and do not vary by year. The fuel consumption as well as the CAP, TAC, and greenhouse gas emissions of a Modernization Project scenario are scaled from those of the Baseline based on the total number of railcars. Table A4.3-TRANS-5 summarizes the scaled emissions associated with switching at the BNSF railyard for various Project scenarios.

4.1.16 Line Haul

The Modernization Project line haul emission factors are the same as those used for the Baseline. The fuel consumption as well as the CAP, TAC, and greenhouse gas emissions of a Modernization Project scenario are scaled from those of the Baseline based on the LPG receipts, additive receipts, LPG and ammonia shipments, and lubricant shipments as presented in Table A4.3-TRANS-7.

4.1.17 Total Emissions Summary

The total rail emissions for various Modernization Project scenarios are summarized in Table A4.3-TRANS-8. The comparisons of CAP, greenhouse gas, and TAC emissions between the Modernization Project scenarios and the Baseline are presented in Table A4.3-TRANS-9.

4.2 OPERATIONAL ON-ROAD MOBILE CAP, GHG AND TAC EMISSIONS

This section describes the methods, data and assumptions used to estimate CAP, GHG and TAC emissions from operational on-road mobile activities associated with the Modernization Project. The Modernization Project includes on-road mobile emission-generating sources such as propane and other chemicals delivery trucks, and sulfur, sodium bisulfite, products, and solid and hazardous wastes shipment trucks. CAP, GHG and TAC emissions from on-road worker vehicles were not included as the increase in workers (i.e., 29 additional workers) and associated increases in worker vehicle trips and emissions due to the Modernization Project are assumed to be negligible. In addition, roadway dust emissions associated with trucks travel on paved roads were also not included as they are assumed to be negligible.

Trucking emissions for the Modernization Project are impacted both by the increase in emissions that would result from the change from Baseline utilization to a reasonably foreseeable utilization, and by the processing of a wider variety of fuels, as sulfur produced by the Facility is removed by trucking. In addition to increasing the trucking emissions to account for the increase in Facility utilization, additional trucks are considered for the additional sulfur produced by the Facility. Similar to the rail analysis, the increased hydrogen plant utilization that is considered as the Modernization Project and the maximum unit rate model (URM) case would not impact trucking activities or emissions.

Figure A4.3-TRANS-1 shows the truck routes from the highway ramps to the Facility boundary. Figures A4.3-TRANS-2 through A4.3-TRANS-8 show the truck routes within the Facility boundary associated with the Modernization Project. CAP and GHG emissions due to on-road trucking resulting from the transport of materials from the on-site delivery areas to the off-site vendors or customer sites were estimated up to the BAAQMD boundary. DPM emissions (a surrogate for TAC emissions, as discussed below) were calculated for on-road trucks from on-site laydown areas to the highway ramps. Additional details are provided in the sections below.

4.2.1 On-Road Mobile Sources CAP and GHG Emissions

4.2.1.1 Source Identification, Physical Scope and Temporal Scenarios for On-Road Mobile Sources' Emissions

This section discusses the emissions estimation of CAPs and GHGs associated with on-road mobile sources. As indicated above, on-road mobile sources include material delivery trucks and product shipment trucks. NO_x , PM_{10} , $\text{PM}_{2.5}$, SO_x , CO ,

ROG, CH₄, N₂O and CO₂ emissions from on-site and off-site activities were calculated for on-road mobile sources.

4.2.1.2 Definition of On-Site and Off-Site Activity

In this section, any on-road mobile activity that occurs within the Facility boundary shown in Figures A4.3-TRANS-2 through A4.3-TRANS-8 is defined as on-site activity. Similarly, any activity that occurs outside of the Facility boundary is defined as off-site activity. “On-site” and “off-site” are terms that refer to the location where emissions occur. The location of TAC emissions is important for the health risk analysis (HRA), as will be discussed later in this section.

4.2.1.3 Physical Domain for CAP and GHG Emissions Inventory

CAP and GHG emissions from operational on-road trucks included emissions from truck on-site and off-site activities from the truck trip origin/destination up to the BAAQMD boundary. Truck trip lengths from the Facility to the trip origin/destination, limited to the distance within the BAAQMD boundary, were provided by Chevron in Chevron Data Transmittal #18 (Rev #2), 2013 and are shown in Table A4.3-TRANS-10.

4.2.1.4 Temporal Scenarios: 2008-2010, Baseline, and Modernization Project

For this analysis, on-road mobile emissions were analyzed for the 2008-2010, Baseline, and the Modernization Project. 2008-2010 period characterizes the actual emissions for the period from 2008 to 2010, and the Baseline projects the 2008-2010 period emissions to the Modernization Project’s commencement year of 2016. The adjustment from the 2008-2010 period emissions to Baseline scenario emissions takes into account more stringent emission controls in newer engines, and reduces the emissions of both CAPs, GHGs and TACs for purposes of the Baseline scenario. The Modernization Project emissions assume that operations begin in 2016.

4.2.2 Overview of On-Road Mobile Sources CAP and GHG Emissions Estimation

On-road mobile emissions were estimated using methods consistent with CalEEMod™, using emission factors from the California Air Resource Board (CARB) Emission Factor 2011 (EMFAC2011) database. EMFAC is California’s model for estimating emissions from on-road vehicles operating in California, and EMFAC2011 is the latest version of that model. The data required to estimate on-road mobile emissions include trip counts and trip lengths, fuel type, fleet mix, model years, and travel speeds. The emissions calculated for trucks include running, idling, brake wear, and tire wear emissions. The truck startup emissions were not quantified because EMFAC2011 does not provide

startup emission factors for diesel trucks. For annual CAP and GHG emissions estimation, the 2008-2010 period emissions were estimated using 2010 emission factors with 2008-2010 activity data. The Baseline emissions was adjusted by projecting 2008-2010 period emissions to the year 2016. Modernization Project and other scenario emissions were estimated for year 2016. Modernization Project and other scenario annual emissions were conservatively estimated for the year 2016 because each subsequent year will have lower emissions from on-road mobile sources than 2016 due to cleaner fleets in subsequent years. 2008-2010 emissions were conservatively estimated for year 2010 because 2010 provides the lowest emissions for any year from 2008 to 2010.

Table A4.3-TRANS-11 shows the emission calculation methodologies for on-road mobile emission sources. More details regarding emissions estimation of operational on-road mobile CAPs and GHGs are provided below, with a discussion of activity data followed by emission factors.

4.2.3 CAP and GHG Inventories On-Site On-Road Mobile Sources Activities: Emission Sources

4.2.3.1 On-Road Mobile Sources

The following sections describe quantification of on-road mobile source emissions emitted on-site; later sections will describe on-road mobile source emissions that are emitted off-site.

4.2.3.1.1 On-Site On-Road Mobile Sources Activity Data

Activity data used to estimate emissions from on-road vehicles include trip counts, trip lengths, and vehicle types. 2008-2010 period and Baseline have the same activity data (for years 2008-2010, inclusive). However, the two scenarios use different sets of emission factors, as described in more detail in sections below. 2008-2010, Baseline and Modernization Project trip lengths were provided by Chevron. The 2008-2010 period trip counts were provided by Chevron, and the Modernization Project trip counts were estimated based on the 2008-2010 period trip counts and the unit rate model (URM) crude oil, gas oil and sulfur production throughputs as described in more detail in Table A4.3-TRANS-14. One-way vehicle trip counts for the Baseline scenario are assumed to be equal to the 2008-2010 period's trip counts.

Delivery and shipment trucks that travel from the Facility to off-site areas have both on-site and off-site on-road activities. This section describes the methodology used to estimate emissions from the on-site activities (i.e., activities that occur between the Facility boundary and the on-site loading/delivery areas). Delivery trucks transport materials from off-site vendors to the

Facility and shipment trucks transport materials from the Facility to off-site customers. The different shipment and delivery trip types and their respective loading/delivery areas within the Facility are presented in Table A4.3-TRANS-12. Emissions were estimated based on trip counts and trip lengths. On-site trip lengths were measured on an aerial photograph based on the trip routes from the Facility boundary to the different truck types' respective on-site loading/delivery areas. Table A4.3-TRANS-10 shows the round trip mileages for trucks that travel both on-site and off-site. Tables A4.3-TRANS-13 and A4.3-TRANS-14 show the trip counts for the 2008-2010, Baseline, and Modernization Project (at both 93% and 100% Utilization Scenarios).

4.2.3.1.2 *On-Site On-Road Mobile Sources Idling Emissions*

For the CAP and GHG inventories, on-road trucks including all delivery and shipment trucks were assumed to idle for 10 minutes at each of two stopping points along their respective on-site travel routes. The delivery and shipment trucks that travel both on-site and off-site were assumed to idle at Facility main gate when entering and exiting the Facility.

This assumption of idling for 10 minutes doubles the maximum allowable⁵ idling scenario under CARB's Heavy-Duty Vehicle Idling Emission Reduction Program (Cal/EPA, CARB, 2013) requirement. The exceptions to the idling limit under CARB's rules, such as for actively moving lines, allow for this method. This approach will also yield conservative results as it is unlikely that a delivery or shipment truck will idle for up to 10 minutes at all points mentioned above during a round trip.

4.2.3.1.3 *On-Site On-Road Mobile Sources Emission Factors*

The emission factors for on-road vehicles were obtained from EMFAC2011. Annual emission rates for EMFAC vehicle class T7 (heavy-heavy duty trucks) were downloaded for Contra Costa County. EMFAC2011 includes emission factors for NO_x, PM₁₀, PM_{2.5}, ROG, TOG,⁶ CO, SO_x, CH₄, N₂O and CO₂. Carbon Dioxide equivalent (CO₂e) emission factors were then estimated using the global warming potentials (GWPs) and CH₄, CO₂ and N₂O emission factors. Global warming potentials are from Appendix E of CARB's LGOP. As specified in the Protocol, the

⁵ Exceptions to the idling rule are detailed in California Code of Regulations Title 13 Chapter 10 Section 2485(d), and include but are not limited to idling periods when the vehicle is queuing at a distance greater than 100 feet from any zoned residential area with at least one residential unit; when the vehicle must remain motionless due to official traffic signals or traffic/weather conditions beyond the control of the driver; and when buses have passengers onboard.

⁶ The TOG class includes all organic gases emitted into the atmosphere. The VOC class does not contain compounds that are exempt from regulation. Thus, TOG may contain more hydrocarbons than VOC from the same source.

Intergovernmental Panel on Climate Change (IPCC)'s Second Assessment Report (SAR) global warming potentials are still used by international convention and in the United States, and are therefore used here. Emission factors for CH₄ and N₂O were not provided in the online emissions database. However, ARB provided methodologies for estimating CH₄ and N₂O emission factors on its EMFAC frequently asked question webpage. CH₄ emission factors were derived by multiplying the TOG emission factors given in EMFAC 2011 online database by 0.058821. N₂O emission factors were calculated using the following formula: 0.3316 g/gallon fuel x gallon fuel for all diesel vehicles / miles traveled for all diesel vehicles. Both the gallons of fuel used for all diesel vehicles in the country and miles traveled for all diesel vehicles in the county can be obtained from the online EMFAC emissions database. All delivery and shipment trucks were conservatively assumed to be diesel-fueled vehicles. To reflect the variability of travel speeds anticipated, the “Aggregated Speeds” option was chosen in EMFAC2011 to estimate emission factors. Emission factors for year 2010 were used for the 2008-2010 period and 2016 emission factors were used for the Baseline, and the Modernization Project. Table A4.3-TRANS-15 summarizes the emission factors used for on-road vehicles for the CAP and GHG emissions inventories.

4.2.3.1.4 On-Site On-Road Mobile Sources Emissions

Table A4.3-TRANS-16 summarizes the combined CAP and GHG on-site and off-site emissions from operational on-road mobile source emissions for the 2008-2010, Baseline, and the Modernization Project 93% and 100% Utilization Scenarios.

4.2.4 CAP and GHG Inventories Off-Site On-Road Mobile Sources Activities: Emission Sources

4.2.4.1 On-Road Mobile Sources

4.2.4.1.1 Off-Site On-Road Mobile Sources Activity Data

There are two general types of vehicles with off-site on-road activity:

- Delivery trucks that transport materials (such as oxygen, lubricants and reagents) from off-site vendors to the Facility boundary. Emissions were estimated based on trip counts and trip lengths. The activity data provided by Chevron included one-way vehicle trip counts for a year for the 2008-2010 period and the combined on-site and off-site trip length of each delivery truck route. Off-site trip lengths were calculated by subtracting the on-site trip lengths (measured using aerial photograph) from the total trip lengths for each type of delivery truck. One-way vehicle trip counts for the Baseline scenario are assumed to be equal to the 2008-2010 period. One-way vehicle trip counts for the Modernization Project and potential future

cases were estimated from the 2008-2010 period one-way trip count based on the URM crude oil, gas oil and sulfur volumes as described in Table A4.3-TRANS-14.

- Shipment trucks that transport materials (such as light products, lubricants and propane) from the Facility boundary to off-site customers. Emissions were estimated based on trip counts and trip lengths. The activity data provided by Chevron included one-way vehicle trip counts for a year for the 2008-2010 period and the combined on-site and off-site trip lengths of each delivery truck route. Off-site trip lengths were calculated by subtracting the on-site trip lengths (measured using aerial photograph) from the total trip lengths for each type of delivery truck. One-way vehicle trip counts for the Baseline scenario are assumed to be equal to the 2008-2010 period. One-way vehicle trip counts for the Modernization Project and potential future cases were estimated from the 2008-2010 period one-way trip count based on the URM crude oil, gas oil and sulfur volumes, as described in Table A4.3-TRANS-14.

Tables A4.3-TRANS-10, -13, and -14 show the activity data for off-site on-road delivery trucks and shipment trucks.

4.2.4.1.2 Off-Site On-Road Mobile Sources Idling Emissions

For the CAP and GHG emissions inventories, ENVIRON assumes that there will be two 10- minute stopping points at each vendor/customer facility. Together with the two on-site 10-minute stopping points, the total idling time for each round trip is 40 minutes.

4.2.4.1.3 Off-Site On-Road Mobile Sources Emission Factors

Because the vehicles that travel off-site also travel on-site, the emission factor values and assumptions used for the on-site on-road mobile source emissions from these vehicles (shown in Tables A4.3-TRANS-15) were also used for their off-site on-road mobile source emissions.

4.2.4.2 Total On-Road Mobile Sources CAP and GHG Emissions

Table A4.3-TRANS-16 summarizes the combined on-site and off-site emissions from operational on-road mobile source emissions for the 2008-2010, Baseline, and the Modernization Project 93% and 100% Utilization Scenarios.

4.2.5 On-Road Mobile Sources Toxic Air Contaminant Emissions

4.2.5.1 Source Identification, Physical Scope and Temporal Scenarios for On-Road Mobile Sources Emissions

This section discusses the emissions estimation of TACs associated with on-road operational mobile sources. Emissions of TACs are estimated to be used in a health risk assessment to assess the health impacts of the Modernization Project. This is further described in *Appendix 4.3-HRA*. Table A4.3-TRANS-17 summarizes the scope of the TAC emission inventory, the details for which are presented in the sections below.

4.2.5.1.1 Physical Domain for TAC Emissions Inventory

Only emissions that are used in the HRA are estimated. Because of this, while the physical domain for the TAC emissions inventory includes all on-site TAC sources, the physical extent of off-site TAC emissions included for the HRA is smaller than the extent of off-site emissions included for the CAP and GHG inventories.

As further discussed in *Appendix 4.3-HRA*, the number of Modernization Project-related trucks on highways is very small relative to highway background traffic; because of this, their emissions will not have a significant adverse health impact on the sensitive population located along the highways. Accordingly, receptors that are exposed only due to their proximity to a highway that may be used by trucks going to and from the Facility were not included in the HRA. The TAC inventory does include Modernization Project-related truck emissions associated with travel along Richmond Parkway, Castro Street, and the highway ramps taken by the vehicles to get on or off the highways.

4.2.5.1.2 Temporal Scenarios: 2008-2010, Baseline, and the Modernization Project

TAC emission inventories were developed for the following scenarios: 2008-2010, Baseline, and the Modernization Project. The emissions were established in the same manner as was done for criteria pollutants. This has the effect of conservatively overstating TAC emissions from trucks for the 70-year period of the HRA, as trucks are getting cleaner.

4.2.5.2 Identification of TACs Generated by the Modernization Project

The TAC emissions inventory includes chemicals emitted from sources that are included for consideration in HRAs consistent with BAAQMD Regulation 2, Rule 5. The TAC emissions inventory for operational on-road mobile emissions includes DPM emissions from diesel on-road vehicles.

Diesel exhaust, a complex mixture that includes hundreds of individual constituents (Cal/EPA, OEHHA, 1998), is identified by the State of California as a known carcinogen (Cal/EPA, OEHHA, 2011). Under California regulatory guidelines, DPM is used as a surrogate measure of carcinogen exposure for the mixture of chemicals that make up diesel exhaust as a whole. Cal/EPA and other proponents of using the surrogate approach to quantifying cancer risks associated with the diesel mixture indicate that this method is preferred over the use of a component-based approach. A component-based approach involves estimating risks for each of the individual components of a mixture. Critics of the component-based approach believe it will underestimate the risks associated with diesel as a whole mixture because the identity of all chemicals in the mixture may not be known and/or exposure and health effects information for all chemicals identified within the mixture may not be available. Furthermore, Cal/EPA has concluded that “potential cancer risk from inhalation exposure to whole diesel exhaust will outweigh the multi-pathway cancer risk from the speciated components” (Cal/EPA, OEHHA, 2003). The PM_{10} emissions from the diesel on-road vehicles were assumed to be equivalent to DPM in the emissions estimation.

4.2.5.3 TAC Emissions from On-Site On-Road Mobile Sources

On-site sources of TAC emissions are diesel on-road vehicles. These sources do not have emission factors specifically for DPM in CARB’s EMFAC 2011 database. DPM is a subset of PM_{10} . PM_{10} engine exhaust emissions from on-site on-road vehicles that were calculated for the CAP inventory for on-site sources were used as conservative, surrogate estimates for DPM. Total $PM_{2.5}$ emissions estimated for the CAP on-site on-road mobile inventory were used for the TAC emission inventory. Table A4.3-TRANS-18 shows the emission factors and Tables A4.3-TRANS-13, A4.3-TRANS-14, and A4.3-TRANS-19 provide the activity data and assumptions. Sections above provide details on the methodology used to estimate PM_{10} and $PM_{2.5}$ emissions.

Table A4.3-TRANS-20 summarizes DPM and $PM_{2.5}$ emissions for all on-road vehicles for both on-site and off-site activities for the 2008-2010, Baseline, and the Modernization Project 93% and 100% Utilization Scenarios.

4.2.5.4 TAC Emissions from Off-Site On-Road Mobile Sources

Off-site sources of TAC emissions are the same as the off-site sources of CAP and GHG emissions discussed in the CAP and GHG inventories section: delivery trucks and shipment trucks. As described previously for the on-site sources, PM_{10} emissions from on-road vehicles that were calculated for the CAP inventory for off-site sources were used as surrogates for DPM. $PM_{2.5}$ emissions calculated for CAP inventory are also used for the TAC inventory. However, for the health risk

analysis, only a subset of the off-site emissions estimated for the CAP inventory were included in the TAC inventory. As described previously, for emissions estimation and dispersion modeling of TACs, off-site on-road mobile source emissions were modeled along the off-site segments of Richmond Parkway, Castro Street, and the highway ramps only.

Additionally, unlike the CAP and GHG inventories, which assumes 20 minutes of idling time for off-site idling activities, no off-site idling activity emissions are considered for the TAC inventory. This is because the idling activities for each round trip at each vendor/customer facility (20 minutes) fall outside of the domain considered for the HRA; see section above for the discussion on the HRA domain. Therefore, for the TAC emissions inventory, each round trip only includes 20 minutes of on-site idling time.

Table A4.3-TRANS-20 summarizes DPM and PM_{2.5} for all on-road vehicles from both on-site and off-site activities for the 2008-2010, Baseline, and the Modernization Project 93% and 100% Utilization Scenarios.

4.2.6 Calculation of Maximum Hourly Emission Rates for Acute Non-Cancer Hazard Analysis

Because DPM as a whole does not have an established Acute Hazard threshold, maximum hourly TAC emissions were not calculated for acute non-cancer hazard evaluation.

Table A4.3-TRANS-2
Switch Emission Factors
Chevron Modernization Project
Richmond, California

Criteria Pollutants

Pollutants	Emission Factors	
	(g/bhp-hr) ¹	(g/gal) ^{2,3}
CO	1.8	27.8
HC ⁴	1.0	15.4
NOx	17.4	264
SOx	--	0.1
PM ₁₀ /PM _{2.5}	0.44	6.7

Greenhouse Gas

Pollutants	Emission Factors	
	(kg/MMBtu) ⁵	(kg/gal) ⁶
CO ₂	73.96	10.2

Toxic Air Contaminant

Pollutants	Emission Factors ⁷	
	(g/bhp-hr)	(g/gal)
DPM	0.44	6.7

Notes:

1. The emission factors for CO, HC, NOx, and PM₁₀ were provided in USEPA's Emission Factor for Locomotives. PM_{2.5} were conservatively assumed to be equal to PM₁₀.
2. The emission factors for CO, HC, NOx, and PM₁₀ were converted into grams per gallon using the switching conversion factor of 15.2 bhp-hr/gal provided in USEPA's Emission Factor for Locomotives.
3. The SOx emission factor were calculated based on the regulatory diesel sulfur content of 15ppm and diesel density of 3.18 kg/gal using the following equation:

$$EF = \text{sulfur content} \times \text{diesel density} \times \text{SO}_2 \text{ molecular weight (64g/mole)} / \text{sulfur molecular weight (32 g/mole)} / 1,000,000 * 1000 \text{ (g/kg)}$$
4. HC is converted to VOC using EPA recommended conversion factor of 1.053.
5. From USEPA Emission Factors for Greenhouse Gas Inventories.
6. Converted based on the high heating value of No.2 fuel oil (0.138 MMBtu/gal) based on USEPA Emission Factors for Greenhouse Gas Inventories.
7. The DPM emission factor is assumed to be same as PM₁₀ emission factor.

Diesel Density 7.05 lb/gal

Notes:

1. Data from 2006 Richmond Railyard TAC Emissions Inventory.
2. Fuel consumption rate from Port of Oakland and 2005 Seaport Air Emissions Inventory.
3. Calculated based on the following formula:

$$\text{Fuel (gal)} = \text{Time in Notch (hr)} \times \text{Fuel Consumption Rate (lb/hour)} / \text{Diesel Density (lb/gal)}$$

Abbreviations:

gal: gallon
hr: hour
lb: pound

Other Data

2006 BNSF Total Locomotives Arriving & Departure⁷

10,725

2006 BNSF Switch Diesel usage⁷

186,159 gal/yr

11369.14519

Notes:

1. Provided in Transmittal #36G
2. Calculated using the following formula:
Chevron Locomotives = Total Railcars / # of Railcar per Unit Train x # of Locomotives per Unit Train x 2
This calculation conservative assumes that the inbound train and the outbound train are not the same train (e.g., trains arrive loaded and leave unloaded) by multiplying the total railcars by 2.
3. Scaled from the 2006 BNSF Switch diesel usage (186,159 gal/yr) using the ratio of Chevron locomotives (655) and total BNSF locomotives (10,725).
4. Calculated using the following formula:
Emissions = Emission Factor (lb/gal or kg/gal) x Fuel Consumption (gal/yr) x unit conversion
5. Assume to be same as PM₁₀.
6. Data from 2006 Richmond Railyard TAC Emissions Inventory.
7. See Table A4.3-Rail-4

Abbreviations:

g: gallon
gal: gallon
kg: kilogram
yr: year

Reference:

Table A4.3-TRANS-6
Line Haul Emission Factors
Chevron Modernization Project
Richmond, California

Criteria Pollutants

Pollutants	Emission Factors	
	2008 - 2010	Baseline and Project
	(g/gal) ^{1,2,3}	
CO	26.6	26.6
HC ⁴	8.7	5.1
NOx	164	121
SOx	0.10	0.10
PM ₁₀ /PM _{2.5}	4.9	3.1

Greenhouse Gas

Pollutants	Emission Factors	
	(kg/gal) ^{5,6}	
CO ₂	10.2	10.2

Toxic Air Contaminant

Pollutants	Emission Factors ⁷	
	(g/gal)	
DPM	4.9	3.1

Notes:

1. The emission factors for CO, HC, NOx, and PM₁₀ were provided in USEPA's Emission Factor for Locomotives. The emission factors for Baseline are the average of 2008, 2009, and 2010 factors and those for 2016 Baseline and Project scenarios are the 2016 factors. Note that the EPA's CO emission factor is a constant for all Tiers so it does not vary by year. PM_{2.5} were conservatively assumed to be equal to PM₁₀.
2. The emission factors for CO, HC, NOx, and PM₁₀/PM_{2.5} were converted into grams per gallon using the switching conversion factor of 15.2 bhp-hr/gal provided in USEPA's Emission Factor for Locomotives.
3. The SOx emission factor were calculated based on the regulatory diesel sulfur content of 15ppm and diesel density of 3.18 kg/gal using the following equation:

$$EF = \text{sulfur content} \times \text{diesel density} \times \text{SO}_2 \text{ molecular weight (64g/mole)} / \text{sulfur molecular weight (32 g/mole)} / 1,000,000 * 1000 \text{ (g/kg)}$$
4. HC is converted to VOC using EPA recommended conversion factor of 1.053.
5. From USEPA Emission Factors for Greenhouse Gas Inventories.
6. Converted based on the high heating value of No.2 fuel oil (0.138 MMBtu/gal) based on USEPA Emission Factors for Greenhouse Gas Inventories.
7. Assume to be same as PM₁₀.

Abbreviations:

bhp: brake horsepower
g: gram
gal: gallon
hr: hour
kg: kilogram
MMBtu: million British thermal units

Input Material and Product Weight⁹

Weight of LPG/Ammonia in a Railcar 64 tons

Weight of Lubricants or Lubricants Related Material in a Railcar 77 tons

Unit Car Weight¹⁰

Railcar Weight 35 tons

Locomotive Weight 175 tons

Buffer Car Weight 80 tons

of Cars and Locomotives per Unit Train¹¹

Locomotive/Unit Train (Loaded) 6

Locomotive/Unit Train (Unloaded) 3

Railcar/Unit Train 96

Buffer Car/Unit Train 4

Other Data

One-Way Distance in Air Basin¹² 65 miles

Average Fuel Efficiency¹³ 955 gross ton-miles/gal

Notes:

- Calculated by multiplying the weight of LPG in a railcar by the number of railcar per unit train from Table A4.3-Rail.1.
- The sum of the LPG, locomotives (loaded), railcars, and buffer cars per train.
 - Weight of LPG per train (e.g., 6,194 tons)÷ weight of LPG in a railcar (e.g., 64 tons) = railcars per unit train (96)
 - Weight of locomotives (e.g., 1,650 tons)÷ locomotive weight (e.g., 175 tons) = locomotives per unit train (loaded) (e.g., 6)
 - Weight of railcars (1,360 tons)÷ railcar weight (35 tons) = railcars per unit train (96)
 - Weight of buffer cars (80 tons)÷ buffer car weight (80 tons) = buffer cars per unit train (8)
- The sum of the locomotives (unloaded), railcars, and buffer cars per train.
- LPG receipt railcars (e.g., 2,014 from Table A4.3-Rail.1) ÷ # railcars per unit train (96)
- Unit train gross weight (inbound) (e.g., 10,924 tons) × unit train per year (e.g., 21.19) × One-way distance in air basin (65 miles)
- Unit train gross weight (outbound) (e.g., 4,205 tons) × unit train per year (e.g., 21.19) × One-way distance in air basin (65 miles)
- Annual gross ton-miles (inbound) (e.g., 15,044,947 ton-mi/yr) + outbound (e.g., 5,791,073 ton-mi/yr) ÷ Average fuel efficiency (955 gross ton-mi/gal)
- See footnotes 1-7
- Calculated using the following formula:
 - Emissions = Emission Factor (g/gal or kg/gal) × Fuel Consumption (gal/yr) × unit conversion
- Provided in Transmittal # 862.
- The longest oil route from Chevron to the boundary of BAAQMD (i.e., from Chevron to Davis).
- Calculated based on the data from 2012 BNSF Railway Class 1 Railroad Annual Report Restatement:
 - Average fuel efficiency (955 gross ton-mi/gal) = 2012 gross ton-mi (1,225,380,290,000) ÷ 971 / 2012 BNSF total diesel consumption (1,287,318,157 gals from freight) ÷ 911

Chevron Data Transmittal #18 Rev #2

Table A4.3-TRANS-11
Methodology of Emissions Calculations Associated with Operational On-road Mobile Activities - Exhaust, Brakewear and Tirewear Emissions
Chevron Modernization Project
Richmond, California

Source	Emission Category	Methodology and Formula	Reference
On-Road Mobile Sources ¹	Exhaust - Running	$E_R = \sum (EF_{Ri} * VMT_i * C)$, where $VMT_i = \text{Trip Length}_i * \text{Trip Number}_i$	EMFAC2011
	Brakewear and Tirewear - Running	$E_W = \sum (EF_{Wi} * VMT_i * C)$, where $VMT_i = \text{Trip Length}_i * \text{Trip Number}_i$	EMFAC2011
	Exhaust - Startup	$E_S = \sum (EF_{Si} * \text{Trip Number}_i)$	EMFAC2011
	Exhaust - Idling	$E_I = \sum (EF_{Ii} * \text{Trip Number}_i)$	EMFAC2011

Notes:

1. On-road mobile sources include all operational onsite (i.e., within Project boundary) and offsite trips. Emissions associated with mobile sources were calculated using equations above and the following parameters and assumptions:

E_R : running exhaust emissions (lb).

EF_{Ri} : running emission factor (g/mile) for vehicle i. From EMFAC2011 online "Emission Rates Database", for all model years of vehicle class T7 in Contra Costa County in 2016 for the Baseline, Project and in 2010 for the 2008-2010 period scenario.

Assumed "AllSpeeds"

VMT_i : vehicle miles traveled for vehicle i

The calculation involves the following data and assumptions:

(1) All shipping and delivery trucks are heavy-heavy duty trucks (EMFAC Category T7).

(3) Trip Length_i: The one-way trip length depends on the vehicle's offsite starting/ending point. Emissions outside the extent of BAAQMD's domain were not considered, as the thresholds were developed assuming that all emission were within the BAAQMD domain, see Table A4.3-TRANS-10 for CAP and Table A4.3-TRANS-19 for TAC.

(4) Trip Number_i: Chevron provided vehicle trip data in Transmittal #18 Rev #2, see Table A4.3-TRANS-13 and Table A4.3-TRANS-14.

E_W : running brakewear and tirewear emissions (lb).

EF_{Wi} : brakewear and tirewear emission factor (g/mile) for vehicle i. From EMFAC2011 online "Emission Rates Database", for all model years of vehicle class T7 in Contra Costa County in 2016 for the Baseline, Project and in 2010 for the 2008-2010 period scenario.

Assumed "AllSpeeds"

VMT_i : vehicle miles traveled for vehicle i

The calculation involves the same data and assumptions used in E_R calculations.

E_S : vehicle startup emissions (lb).

EF_{Si} : vehicle startup emission factor (g/trip) for vehicle i. From EMFAC2011, which reports startup emissions in tons/day. The emission factor (g/trip) is calculated by dividing the emissions by the total number of trips per day for each vehicle category.

E_I : vehicle idling emissions (lb).

EF_{Ii} : vehicle idling emission factor (g/trip) for vehicle i. From EMFAC2011, which reports emission factors in g/hr-vehicle. The emission factor is calculated to assume an average idling time per trip. For CAP emissions inventory, it was assumed that four 10-minute idling points occur for a round trip. For TAC emissions inventory, it was assumed that two 10-minute idling points occur for a round trip.

C: unit conversion factor (lb/g).

Abbreviations:

ARB - California Air Resources Board

AQ - air quality

CAP - criteria air pollutant

EF - Emission Factor

EMFAC - Emission FACtor Model

g - gram

lb - pound

mi - mile

min - minute

TAC - toxic air contaminant(s)

T7 - EMFAC Category for Heavy Heavy Duty Truck

TRANS - transportation

VMT - vehicle miles traveled

Notes:

1. Round trips and one-way trip count information were provided by Chevron. One-way trip count is round trip count multiplied by 2.
2. 2016 Baseline scenario uses the same trip count information as the existing setting Baseline scenario.
3. Actual truck counts from Chevron.
4. Truck counts were estimated by Chevron Refinery Transportation Manager.
5. Truck counts were estimated by Chevron based on actual volumes and typical truck loads.
6. Chevron estimated truck counts by scaling Feb-Dec 2010 actual truck counts up to 12 months; all other baseline records are no longer available.

Notes:

1. Except for CH₄ and N₂O, all emission factors were extracted from EMFAC2011 online "Emission Rates Database", for all model years of vehicle class T7, for all speed, for Contra Costa County. Calendar year was 2010 for existing setting Baseline scenario, and 2016 for the 2016 Baseline and Project.
2. EMFAC2011 splits the heavy-heavy duty trucks (EMFAC Category T7) to various sub-categories. However the EMFAC2011 online database has an option of generating emission factors for EMFAC2007 categories where sub-categories are grouped. The emission factors for the T7 categories used for this analysis were generated by that option.
3. Per ARB's guidance, CH₄ emission factors were derived by multiplying the TOG emission factors given in EMFAC 2011 by 0.058821.
4. Per ARB's guidance, N₂O emission factors were calculated using the following formula: 0.3316 g/gallon fuel x gallon fuel for all diesel vehicles / miles traveled for all diesel vehicles.
5. CO₂e emission factors include the sum of CO₂, N₂O and CH₄ emission factors multiplied by their respective global warming potentials, as follows: CO₂e = (CO₂ x 1) + (CH₄ x 21) + (N₂O x 310). Global warming potentials are from Appendix E of CARB's LGOP. As specified in the Protocol, the Intergovernmental Panel on Climate Change (IPCC)'s Second Assessment Report (SAR) global warming potentials are still used by international convention and in the United States, and are therefore used here.

APPENDIX 4.3 - URM

URM: Unit Rate Model

February 26, 2014

Ms. Shari Libicki
Environ
201 California St. #1280
San Francisco, CA 94111

Re: EIR for the Chevron Richmond Refinery Revised Renewal Project - Unit Rate Model Development and Use

Dear Shari:

Turner, Mason & Co. was engaged by Environ to provide refinery technical expertise to the City of Richmond for the development of an environmental impact report (EIR) for the Chevron Richmond Revised Renewal Project. The major changes in the refinery associated with the project include:

1. Construction of a new hydrogen plant to replace the existing plant (approximately 244 mmscf/d replacing a nominal 170 mmscf/d),
2. Increase the capacity of the FCC FHT from 65,000 b/d to 80,000 b/d, and
3. Increase the capacity of the sulfur recovery units from a nominal 600 long tons per day (lt/d) to 900 lt/d.

In addition to other tasks, TM&C was asked to develop a refinery unit rate model (URM) to 1) determine process unit rates in the refinery related to the use of different crude oil input blends, as well as, 2) expected sulfur recovery rates based on the sulfur content of crude and gas oil used by the refinery, and 3) the hydrogen production that the refinery would use from the proposed new hydrogen plant. TM&C was also asked to conduct several URM runs that included a range of potential crude oil blend inputs, and crude and gas oil sulfur contents, under pre- and post- Modernization Project conditions. TM&C developed the URM and conducted several URM runs over the period 2011-2014. The primary sources used to develop the model include:

Chevron Transmittal # 1, Revision #1

Chevron Transmittal #3C Rev. #2

Robert A Meyers, Handbook of Petroleum Refining Processes, Third Edition, (McGraw-Hill, 2004) page 10.27 and page 14.36.

M. D. Edgar, A. D. Johnson, J. T. Pistorius and T. Varadi, "Troubleshooting on Hydrotreating Units," National Petroleum Refiners Association Meeting, paper no. AM-84-38, page 7 (1984).

February 26, 2014

Page 2

The technical report describing the URM, and several pre- and post- Modernization Project URM runs, is attached to this letter. The report accurately describes the URM, and accurately summarizes the URM results TM&C obtained for each of the scenarios in the report.

Sincerely,

A handwritten signature in black ink, appearing to read "Tom Hogan", with a stylized, cursive script.

Thomas R. Hogan
Senior Vice President
Turner, Mason & Co

APPENDIX 4.3

URM: UNIT RATE MODEL TECHNICAL APPENDIX

4.1 OVERVIEW

This technical appendix describes the unit rate model (URM) that was developed to estimate how the Chevron Richmond Refinery's (Facility's) processing units could potentially be used under post-Modernization Project conditions. The URM generates estimates of the daily average throughput or production of various Facility process units in relation to: (a) the amount of crude and gas oil inputs into the Facility; (b) the API gravity and fractional characteristics¹ of the crude oil inputs; and (c) the sulfur content of the crude and gas oil inputs.

Information used in the model was derived from the Facility's average daily operational activity and crude and gas oil inputs for the 3-year period 2008-2010 (the "Baseline Period"). The Baseline Period data was utilized to estimate how crude oil fractions and externally sourced, or purchased, gas oil would be allocated to specific process units. Applicable process unit throughputs were adjusted in the URM to reflect proposed post-Modernization Project permit limits, including a reduction in the permitted throughput limit of the Facility's solvent de-asphalting (SDA) unit to an annual average of 50,000 barrels per day (b/d).

The URM was designed to determine the volume of gas oil purchased by the Facility based on: (a) the amount of gas oil obtained from the crude oil blend used by the Facility; and (b) the percentage of total permitted gas oil capacity used by the five units that can initially process purchased gas oil in the Facility (the "gas oil gateway units"). As discussed below, the air quality analysis in the EIR considers URM cases that maximize total crude and gas oil use assuming that the crude and gas oil gateway units operate at 100% and 93% of post-Modernization Project permitted capacity.² The Facility did not operate at 100%

¹ As discussed in Chapter 4.0 of this EIR, crude oil is input to the Facility and distilled in the crude unit into specific fractions of oil defined by boiling temperatures. The phrase "fractional characteristics" refers to the relative proportion of each fraction in the crude oil that enters the Facility crude unit.

² A 93% utilization rate is used in the Modernization Project EIR based on annual refinery utilization data for the western United States (Petroleum Administration Defense District Region V, or "PADD V") by the U.S. Energy Information Administration (EIA). Annual average PADD V refinery utilization rates are available for 1985-2012 (http://www.eia.gov/dnav/pet/pet_pnp_unc_dcu_r50_a.htm, accessed February 17, 2014) and averaged approximately 86.7% per year over this period. The highest annual average

or 93% of existing capacity during the entire Baseline Period, and for a variety of reasons refineries typically do not, or are not able to continuously operate at full capacity for annual durations. As a result, the URM results based on 100% and 93% crude unit and gas oil gateway unit capacity utilization provide a conservative estimate of the extent to which the Facility could be operated under post-Modernization Project conditions.

Table A4.3-URM-1 lists the Facility process units analyzed in the URM. Figure A4.3-URM-1 graphically depicts the relationship between the processing units analyzed in the URM.

TABLE A4.3-URM-1 FACILITY OPERATING UNITS INCLUDED IN THE URM

Crude Unit – Atmospheric Column	Polymerization Unit (Poly)
Crude Unit – Vacuum Column	Hydrocracker
Naphtha Hydrotreater (NHT)	Richmond Lube Oil Plant (RLOP)
Catalytic Reformers	LNC--light neutral hydrocracker
Pen/Hex Isomerization Unit (Pen/Hex)	LNF-light neutral hydrofinisher
Jet Hydrotreater (JHT)	HNC--heavy neutral hydrocracker
Diesel Hydrotreater (DHT)	HNF--heavy neutral hydrofinisher
Fluidized Catalytic Cracker Feed Hydrotreater (FCC FHT)	Solvent De-Asphalting (SDA) Unit
Fluid Catalytic Cracker (FCC) Unit	Sulfur Recovery Unit (SRU)
Gasoline Hydrotreater (GHT)	Hydrogen Plant
Alkylation Unit	

As shown in Figure A4.3-URM-1, gas oil obtained from the crude unit, and high- and low-sulfur gas oil purchased by and shipped to the Facility, is initially processed by one of five gas oil gateway units: the fluidized catalytic cracker feed hydrotreater (FCC FHT); the fluid catalytic cracker (FCC); the hydrocracker; and the light neutral hydrocracker (LNC) and heavy neutral hydrocracker (HNC) in

utilization rate was approximately 92.7% in 1998. To provide a conservative assessment, the EIR includes the analysis of 93% utilization cases to reflect the highest PADD V annual average refinery utilization rate reported by the EIA over 1985-2012.

Figure A4.3-URM-1
Chevron Refinery Modernization Project EIR
General Facility Unit Flow Chart

the Richmond Lube Oil Plant (RLOP), which is a part of the Facility that produces lubricating oils. The percentage of total gas oil gateway unit permitted capacity that is utilized under future conditions is an input to the URM in each case. The model determines how much of the applicable gas oil gateway unit capacity will be supplied from the crude oil blend used by the Facility, and calculates how much additional gas oil must be purchased to achieve the specified utilization rate. In a 100% scenario, for example, the URM calculates the amount of gas oil the Facility would need to purchase, in addition to gas oil obtained from the applicable crude oil blend, to operate the gas oil gateway units at 100% of permitted capacity.

Several units, primarily the Facility hydrocrackers and hydrotreaters, use hydrogen to assist in the cracking process and remove sulfur in the form of hydrogen sulfide gas. These units are supplied with hydrogen produced by the Facility's catalytic reformers and the hydrogen plant, as well as hydrogen recovered from Facility process gas. The hydrogen sulfide gas created as a result of sulfur removal is separated from the hydrocarbon stream, conveyed to the sulfur recovery unit (SRU) and is recovered as elemental sulfur. The recovered sulfur is sold as "sulfur product" for agricultural and other uses.

The URM calculates SRU use rates under post-Modernization Project conditions as a function of the sulfur load into the refinery less the sulfur contained in the fuel oil blendstock that exits the Facility from the SDA. To provide a conservative assessment of emissions related to hydrogen production for extracting sulfur from various units, the URM assumes that all of the net sulfur load (crude blend sulfur minus the sulfur that exits the Facility as fuel oil blendstock from the SDA) to the Facility will be processed and recovered by the SRU, although very small amounts of sulfur exit the Facility as sulfur dioxide, due to the combustion of small amounts of sulfur in the Facility fuel gas, or in finished products. The heavy bottom discharge from the FCC unit also contains sulfur that is not further processed in the Facility or recovered by the SRU, but represents a small amount of the total sulfur input as well.

The URM was utilized to calculate Facility process unit throughput, sulfur recovery and hydrogen plant production levels under post-Modernization Project conditions using a representative selection of crude data to understand the effect of processing a range of heavier and lighter crude oil blends, higher or lower crude and gas oil sulfur contents, and greater or lower purchased crude and gas oil volumes. To provide a conservative assessment, while the crude blends analyzed in the "Modernization Project Related Cases" (see *Section 4.3.1.A*) are meant to be representative of crude blends that could be processed under post-Modernization Project operating conditions, the crude blends for these and other URM cases were generally considered without regard to feasibility due to factors such as accessibility, fractional properties that are

incompatible with the range of crudes that the Facility is designed to process, or chemical properties, such as excessive acidity that would damage certain Facility processing units (see *Chapter 4.13, Public Safety*).

As discussed below, the Modernization Project EIR focuses on eight representative cases derived from the URM, including: (a) four cases based on 100% crude and gas oil gateway unit capacity utilization (100% Utilization scenarios); and (b) four cases based on 93% crude and gas oil gateway unit capacity utilization (93% Utilization scenarios). This URM appendix also discusses (a) three cases that illustrate model results based on Facility use of extremely light, extremely heavy and very high sulfur content crude oil; (b) two no-Modernization Project cases considered in the alternatives sections of the EIR assuming the Facility operates at 93% and 100% of the crude and gas oil gateway unit capacity without Modernization Project changes and using the average daily crude oil blends and gas oils from the Baseline Period; and (c) two “limited sulfur capacity” cases considered in the alternatives sections of the EIR assuming the Facility operates at 93% and 100% of the crude and gas oil gateway unit capacity under post-Modernization Project conditions but with a lower SRU capacity of 750 long tons per day (lt/d). For informational purposes, several other URM analysis results that were considered during the preparation of the Modernization Project EIR are included in Attachment 3.

4.2 URM METHODOLOGY

This section discusses the principal URM analysis methods for evaluating the post-Modernization Project process unit throughput rates related to processing heavier or lighter crude oil, crude or gas oil with higher or lower sulfur contents and different crude and gas oil capacity utilization levels, including: (1) the approach used to develop the URM from Baseline Period operational data; and (2) the methodologies used to estimate the volume of crude and gas oil use, sulfur removal and production, and hydrogen demand and production by the Facility under post-Modernization Project conditions.

4.2.1 Unit Rate Model Development

As illustrated in Figure A4.3-URM-1, crude oil blends enter the Facility through the crude unit and are distilled by heating into various fractions. These fractions are then fed to other process units within the Facility. The amount of each fraction is determined by the crude oil feedstock blend that enters the crude unit. Crude and gas oil feedstocks also contain varying amounts of sulfur that must be processed and removed from the Facility’s products. Sulfur removal requires the use of hydrogen gas produced by other Facility operations and the hydrogen plant. The URM was developed to analyze how crude blend feedstocks with different fractional characteristics, and crude and gas oil feedstocks with different sulfur contents, would affect each unit’s throughput volume. The

results were utilized to calculate processing volume-related emissions considering a variety of potential future crude blend and gas oil use scenarios.

The URM was developed by using publicly available technical resources and historical, average daily Facility crude and gas oil use and process unit throughputs provided by the Modernization Project applicant for 2008-2010 (the “Baseline Period”), including the average crude oil blend fractional characteristics and the sulfur content of the Facility feedstocks. Table A4.3-URM-2 summarizes the fractional characteristics and sulfur content of the average crude oil blend and the sulfur content of the purchased gas oil (gas oil shipped to the refinery to supplement gas oil obtained from the crude oil feedstock) during the Baseline Period.

TABLE A4.3-URM-2 BASELINE PERIOD CRUDE OIL BLEND CHARACTERISTICS AND CRUDE AND GAS OIL SULFUR CONTENT

Fraction (Boiling Point, °F)	Volume of Crude Supply (%)
Crude Oil Fractional Characteristics	
Butane and Lighter Fractions	2.21
Naphtha (55-290)	19.29
Kerosene (290-510)	22.12
Diesel (510-625)	11.16
Gas Oil (625-770)	12.99
Heavy Gas Oil (770-1020)	17.25
Residuum (1020+)	14.99
Weight and Sulfur Content	
Crude Oil API Gravity (degrees)	33.7
Crude Oil Specific Gravity	0.857
Crude Oil Sulfur Content (wt. %)	1.58%
Sour Gas Oil Sulfur Content (wt. %)	1.5%
Sweet Gas Oil Sulfur Content (wt. %)	0.3%

As shown in Table A4.3-URM-2, during the Baseline Period, the Facility generally processed crude oil blends with an average gravity in the light end of the intermediate range and with an average API gravity of approximately 33.7

degrees (°). The crude oil sulfur content by weight during the Baseline Period was approximately 1.58% by weight.³ The Facility also purchased “sweet” gas oil with an approximate sulfur content by weight of 0.25% for FCC unit processing, and “sour” gas oil with an approximate sulfur content by weight of 1.5% for processing by other gas oil units (see Table A4.3-URM-1 for process unit acronym definitions).

The crude oil fractional characteristics, gravity⁴ and sulfur content data summarized in Table A4.3-URM-2 are inputs required by the URM to complete the analysis of each case and are derived from applicable crude oil assay data. These and other URM inputs are listed in Attachment 1 and include: (1) the crude oil blend fractional characteristics (percent of each fraction in the crude oil blend); (2) the crude oil blend sulfur content by percent weight; (3) the crude oil blend specific gravity; (4) the amount of total crude oil sulfur contained in the residuum and processed in the SDA; and (5) gas oil sulfur content by percent weight. These inputs will vary with different crude oil blends and gas oils that may be purchased for the Facility. As discussed below, the URM also uses the specific gravity of gas oil as an input to calculate the amount of sulfur recovered by the SRU, but this value is assumed to be 0.91.⁵

Table A4.3-URM-3 summarizes the average daily volume of crude and gas oil and unit throughput rates for the Facility during the Baseline Period and compares these rates to the applicable unit annual average permit limit under Title V of the federal Clean Air Act. During the Baseline Period, the Facility used approximately 227,900 b/d of crude oil and approximately 45,400 b/d of gas oil, including 34,500 b/d of “sweet” gas oil. Total crude and gas oil inputs were approximately 273,300 b/d. On an average daily basis, none of the Facility units included in the URM operated at applicable permitted limits during the Baseline Period.

³ All references to sulfur content in this technical appendix are expressed in terms of percent sulfur by weight.

⁴ The API and specific gravity of a crude oil are different methods for expressing the same measure of weight or crude oil gravity. For calculation purposes, the URM uses the applicable specific gravity. For ease of reference, crude oil weights are generally described in terms of °API in the text of this appendix.

⁵ The Modernization Project applicant has indicated that the gas oil purchased typically ranges from 22-36 °API. A specific gravity of 0.91 (24 °API) is near the lower end (heavier) of the API range and therefore provides a conservative estimate of the gas oil specific gravity used in the Facility.

TABLE A4.3-URM-3 BASELINE PERIOD FACILITY AVERAGE DAILY OPERATIONS

Oil Source	Input Rate (b/d)	Existing (pre-Modernization Project) Annual Average Daily Limit (b/d)	Percent Existing Permit Limit Utilized
Crude and Gas Oil Inputs			
Crude Oil	227,900	257,200	88.6%
Sweet Gas Oil	34,500	N/A	
Sour Gas Oil	10,900	N/A	
TOTAL	273,300		
Operating Unit	Use Rate (b/d Except Where Noted)	Existing (pre-Modernization Project) Annual Average Daily Limit (b/d)	Percent Existing Permit Limit Utilized
Process Unit Throughput/Production Rates			
Crude Unit – Atmospheric Column	227,900	257,200	88.6%
Crude Unit – Vacuum Column ^a	89,900	N/A	
NHT	49,800	57,600	86.5%
Catalytic Reformers	45,500	68,700	66.2%
Pen/Hex Isomerization Unit	24,600	65,000	37.8%
Butane Isomerization (Butamer) Unit ^b		12,000	
JHT	61,100	96,000	63.6%
DHT	28,800	64,800	44.4%
FCC FHT	36,300	65,000	55.8%
FCC	70,500	80,000	88.1%
GHT	17,200	64,800	26.5%
Alkylation Unit	27,700	36,000	76.9%
Polymerization Unit	6,700	8,000	83.8%
Hydrocracker	45,000	51,300	87.7%
Richmond Lube Oil Plant (RLOP)			
<i>LNC – light neutral hydrocracker</i>	12,600	16,500	76.4%

TABLE A4.3-URM-3 BASELINE PERIOD FACILITY AVERAGE DAILY OPERATIONS

Oil Source	Input Rate (b/d)	Existing (pre-Modernization Project) Annual Average Daily Limit (b/d)	Percent Existing Permit Limit Utilized
<i>LNF – light neutral hydrofinisher</i>	15,400	22,000	70.0%
<i>HNC – heavy neutral hydrocracker</i>	20,600	26,000	79.2%
<i>HNF – heavy neutral hydrofinisher</i>	6,000	12,000	50.0%
Solvent De-Asphalting (SDA) Unit	33,900	56,000	67.8%
Sulfur Recovery Unit (SRU)(long tons/day)	398	600	66.3%
Hydrogen Plant production (mmscfd)	164	181.1 ^c	90.6%

Note: b/d = barrels per day; mmscfd= million standard cubic feet per day.

^a The Baseline Period throughput level for the crude unit - vacuum column is a URM model estimate based on the average crude oil blend assay data and total feed to the crude unit.

^b The butane isomerization (butamer) unit does not have an associated furnace and does not generate combustion-related emissions. As discussed below, the unit has been included in the analysis of hydrogen demand and does not otherwise affect the URM. The butamer unit permit limit is included for informational purposes in Table A4.3-URM-4.

^c The permit limit for the existing hydrogen plant is not adjusted for purity. Existing hydrogen plant production is approximately 94% hydrogen. As a result, the actual amount of hydrogen available for Facility use at the existing plant's full capacity is approximately 170.2 mmscfd.

Based on the Baseline Period data provided by the Modernization Project applicant and other technical sources, the URM allocates crude and gas oil feedstocks to the Facility process units using the parameters listed in Attachment 2. The URM also incorporates the increased throughput limits for the FCC FHT, the new hydrogen plant and the SRU, and the 50,000 b/d limit on the SDA throughput, that would result from the proposed Modernization Project. These throughput limit changes are listed in Table A4.3-URM-4.

4.2.2 Crude Unit Capacity Utilization

The Facility is permitted to process up to 257,200 b/d of crude oil and this limit would not be modified by the Modernization Project. The percentage of the crude unit's capacity that is used in each case is specified as an input to the URM (see Attachment 1). A 93% utilization scenario, for example, analyzes Facility unit throughput volumes that result from using 93% of the crude unit's permitted capacity, or approximately 239,200 b/d.

**TABLE A4.3-URM-4 EXISTING AND POST-PROJECT UNIT THROUGHPUT PERMIT LIMITS
(CHANGES IN BOLD)**

Process Unit (b/d except where noted)	Existing Permit Limit	Post- Modernization Project Permit Limit	Post- Modernization Project Change
Crude Unit – Atmospheric Column	257,200	257,200	0
Crude Unit Vacuum Column ^a	n/a	n/a	n/a
NHT	57,600	57,600	0
Catalytic Reformers	68,700	68,700	0
Pen/Hex Unit	65,000	65,000	0
Butane Isomerization Unit (Butamer)	12,000	12,000	0
JHT	96,000	96,000	0
DHT	64,800	64,800	0
FCC FHT	65,000	80,000	15,000
FCC	80,000	80,000	0
GHT	64,800	64,800	0
Alkylation Unit	36,000	36,000	0
Polymerization Unit	8,000	8,000	0
Hydrocracker	51,300	51,300	0
Richmond Lube Oil Plant (RLOP)			
<i>LNC--light neutral hydrocracker</i>	16,500	16,500	0
<i>LNF--light neutral hydrofinisher</i>	22,000	22,000	0
<i>HNC--heavy neutral hydrocracker</i>	26,000	26,000	0
<i>HNF--heavy neutral hydrofinisher</i>	12,000	12,000	0
SDA Unit	56,000	50,000	-6,000
SRU Plant (lt/d)	600	900	300
Hydrogen Plant production (mmscfd)	181.1^b	244	63

Note: b/d = barrels per day; mmscfd= million standard cubic feet per day; lt/d = long tons per day.

^a The Crude Unit's vacuum column only receives feed directly from the crude unit's atmospheric column.

^b The permit limit for the existing hydrogen plant is not adjusted for purity. Existing hydrogen plant production is approximately 94% hydrogen. As a result, the actual amount of hydrogen available for Facility use at the existing plant's full capacity is approximately 170.2 mmscfd.

The Facility's ability to process crude oil that is much heavier or lighter than the crude oil blend used during the Baseline Period is subject to two existing constraints that would not be affected by the Modernization Project: (1) the SDA throughput limit for heavier crude oils, and (2) the NHT throughput limit for lighter crude oils.

In general, heavier crude oil contains a proportionately larger share of heavier fractions, including the heaviest fraction, the residuum. The entire residuum fraction in the crude blend feedstock to the Facility is routed from the crude unit to the SDA unit for further processing. In the SDA unit, the residuum is separated into either de-asphalted oil (DAO), which is then routed to other Facility units, or fuel oil blendstock, which exits the Facility from the SDA. The SDA annual average throughput limit under existing permits is 56,000 b/d, but equipment limitations and other factors do not allow the unit to operate at more than an annual average throughput of 50,000 b/d. The Facility is not equipped with alternative process units or sufficient storage and treatment facilities to manage the residuum other than by routing this fraction to the SDA unit. The Modernization Project will not add any additional residuum processing or storage capacity to the Facility, and the Facility will commit to limiting SDA throughput by permit to 50,000 b/d on an annual average basis as a result of the Modernization Project. Consequently, under post-Modernization Project conditions, the Facility will be unable to process crude oil blends up to the permitted maximum of 257,200 b/d that contain more than 50,000 b/d of residuum on an annual average basis.

The Facility's ability to process much lighter crude blends than during the Baseline Period is constrained by the NHT throughput permit limit of 57,600 b/d. The NHT processes all of the naphtha fraction separated by the crude unit and receives additional feed from other Facility process units (see Attachment 2). The Facility is not equipped with alternative process units or sufficient storage and treatment facilities to process or store naphtha other than by routing these fractions to the NHT. The Modernization Project will not add any additional naphtha processing or storage capacity to the Facility, and the existing NHT throughput limit will not be modified by the Modernization Project. Consequently, under post-Modernization Project conditions, the Facility will be unable to process crude oil blends up to the permitted maximum of 257,200 b/d that, in combination with naphtha from other Facility units, would exceed 57,600 b/d of naphtha.

Table A4.3-URM-5 illustrates how the volume of heavier and lighter crudes could be constrained by the SDA and NHT unit throughput limits. Heavier crudes (e.g., Eocene crude with an approximate API of 18.3°) can contain more residuum than can be processed by the SDA at maximum crude rates. Eocene crude assay data, for example, indicates that 37.2% of the crude oil consists of residuum. The

Facility would be unable to process more than approximately 135,000 b/d of this crude oil blend without exceeding the SDA unit's 50,000 b/d limit.

Lighter crudes, (e.g., 100% Bakken crude with an approximate API of 41°) that contain a significantly higher amount of the naphtha fraction would, in combination with feeds routed from other Facility units, also be processed through the crude unit at a lower rate than the permitted limit. As illustrated in Table A4.3-URM-5, 100% Bakken crude assay data indicates that approximately 25% of the crude oil consists of the naphtha fraction. Feed from other Facility units also accounts for a portion of the NHT throughput. The Facility would be unable to process more than approximately 199,300 b/d of Bakken crude oil without exceeding the NHT unit's 57,600 b/d capacity.

In summary, to provide a conservative assessment, the URM is designed to use as much crude oil as possible up to the level of the crude unit's capacity utilization that is input to the model. The model can be iteratively run to identify crude oil blends that can be used by the Facility up to the 50,000 b/d SDA, the 57,600 b/d NHT, or any other unit's permit limit that might be exceeded before the specified level of crude unit capacity could be fully utilized.

4.2.3 Gas Oil Capacity Utilization

As discussed in *Chapter 4.0* of this EIR, gas oil is separated from crude oil by the crude unit and DOA is separated from the residuum by the SDA unit. There are no permit limits on the amount of gas oil that can be purchased for Facility use, and the total volume of gas oil utilization is limited by the capacity of the gas oil gateway units. Throughput limits for four gas oil gateway units—the FCC, the hydrocracker; the LNC and the HNC—would not be modified by the Modernization Project. The Modernization Project would increase the permitted throughput limit of the FCC FHT, the fifth gas oil gateway unit, by 15,000 b/d, which would increase the Facility's total gas oil processing capacity by approximately 1,200 b/d (see EIR *Chapter 3.0, Project Description, Section 3.3.2.1*). The URM accounts for the gas oil processing capacity increases that would result from the Modernization Project under future conditions.

The percentage of the gateway gas oil units' capacity that is used in each case is specified as an input to the URM (see Attachment 1). A 93% Utilization scenario, for example, analyzes Facility unit throughput volumes that result from using 93% of the crude unit and the gas oil gateway unit capacities. The amount of gas oil purchased for Facility use is calculated in the following manner:

1. Calculate the amount of gas oil required to operate the gas oil gateway units under post-Modernization Project conditions at the specified utilization level (e.g., 93%, 100% etc.);

TABLE A4.3-URM-5 ILLUSTRATION OF POTENTIAL CRUDE OIL USE CONSTRAINTS

Fraction Name and Boiling Point (°F)	Percent of Crude Supply	Volume of Each Fraction (b/d, rounded to nearest 100)	Does the volume of a crude oil fraction result in a Facility feed that exceeds a processing unit throughput permit limit?
Baseline Period Crude Oil Blend (API = 33.7°)			
Butane and Lighter Fractions	2.21	5,700	NO
Naphtha (55-290)	19.29	49,600	NO
Kerosene (290-510)	22.12	56,900	NO
Diesel (510-625)	11.16	28,700	NO
Gas Oil (625-770)	12.99	33,400	NO
Heavy Gas Oil (770-1020)	17.25	44,400	NO
Residuum (1020+)	14.99	38,600	NO
<i>Volume Crude Oil Use Without Exceeding a Processing Unit Throughput Limit</i>		257,200	
Heavier Crude Oil (e.g., Eocene crude, API = 18.3°)			
Butane and Lighter Fractions	0.67	900	NO
Naphtha (55-290)	7.07	9,500	NO
Kerosene (290-510)	12.72	17,200	NO
Diesel (510-625)	9.24	12,500	NO
Gas Oil (625-770)	12.30	16,600	NO
Heavy Gas Oil (770-1020)	20.98	28,300	NO
Residuum (1020+)	37.02	50,000	YES: SDA
<i>Volume Crude Oil Use Without Exceeding a Processing Unit Throughput Limit</i>		135,000	
Light Crude Oil (e.g., 100% Bakken, API = 41°)			
Butane and Lighter Fractions	2.87	5,700	NO
Naphtha	25.20	50,200 ^a	YES: NHT^a
Kerosene (290-510)	26.54	52,900	NO
Diesel (510-625)	11.61	23,100	NO
Gas Oil (625-770)	11.82	23,600	NO

TABLE A4.3-URM-5 ILLUSTRATION OF POTENTIAL CRUDE OIL USE CONSTRAINTS

Fraction Name and Boiling Point (°F)	Percent of Crude Supply	Volume of Each Fraction (b/d, rounded to nearest 100)	Does the volume of a crude oil fraction result in a Facility feed that exceeds a processing unit throughput permit limit?
Heavy Gas Oil (770-1020)	15.20	30,300	NO
Residuum (1020+)	6.77	13,500	NO
<i>Volume Crude Oil Use Without Exceeding a Processing Unit Throughput Limit</i>		199,300	

^a The throughput total includes Facility feeds from other units as well as the naphtha fraction from the crude oil feedstock. If 100% Bakken crude with the fractional characteristics identified in Table A4.3-URM-5 was used by the Facility, the URM indicates that total NHT throughput from all feed sources would reach the 57,600 b/d NHT processing limit. The amount in the table is the naphtha feed from the crude unit alone not including feed from other Facility units.

2. Calculate the amount of gas oil supplied from crude oil based on the fractional characteristics of the crude oil blend used in the applicable scenario and the specified crude unit utilization (e.g., 93%, 100%, etc.);
3. Calculate the amount of gas oil that is an intermediate product of other internal Facility process units (e.g. hydrotreated gas oil from FCC FHT or DAO recovered from residuum by the SDA); and
4. Calculating the total maximum volume of purchased gas oil by subtracting (a) the amount of gas oil obtained from crude oil and from internal Facility processes from (b) the amount of gas oil required to operate the gas oil gateway units under post-Modernization Project conditions at the specified utilization level.

To provide a conservative assessment, the URM assumes that all of the purchased gas oil under post-Modernization Project conditions will consist of “sour” feedstock with higher sulfur content except for purchased gas oil routed directly to the FCC. To meet product sulfur content specifications, the FCC only processes low-sulfur, “sweet” gas oils. Based on the URM model parameters listed in Attachment 2, and to provide a conservative assessment of the amount of sulfur in purchased gas oil, the URM assumes that approximately 4,000 b/d of sweet gas oil will be purchased under post-Modernization Project conditions to operate both the FCC and the FCC FHT at full permitted capacity (the amount of sweet gas oil is scaled by the specified level of utilization in cases that assume

less than 100% utilization). In comparison, the Facility purchased approximately 34,500 b/d of sweet gas oil during the Baseline Period.

The method by which the URM calculates gas oil imports is illustrated in Table A4.3-URM-6 for a scenario that assumes 100% of the gas oil gateway unit capacity is utilized and that the crude oil feedstock has the same fractional characteristics as during the Baseline Period (see Table A4.3-URM-3).

Approximately 253,800 b/d of gas oil would be required to operate the gas oil gateway units at full capacity. Approximately 77,800 b/d of gas oil would be obtained from the crude oil feedstock, and 110,800 b/d would be produced by other Facility processing units. Crude oil and internal Facility processing would therefore generate a gas oil supply of 188,600 b/d. As a result, approximately 65,200 b/d of gas oil would be purchased to operate the gas oil gateway units at full capacity (253,800-188,600 b/d). The amount of gas oil purchased under post-Modernization Project conditions varies with (a) the fractional characteristics of the crude oil feedstock, (b) the percentage of the crude unit's total capacity use, and (c) the percentage of total gas oil gateway unit capacity use that are entered as inputs to the URM (see Attachment 1).

4.2.4 Sulfur Content and SRU Analysis

The Modernization Project would increase the Facility's sulfur recovery or sulfur production limit from approximately 600 lt/d⁶ to 900 lt/d. The crude and gas oil used in the Facility contains sulfur that must be removed during the refining process. The URM assumes that all sulfur entering the Facility in crude or gas oil will exit the Facility either in the fuel oil blendstock produced by the SDA unit, or as elemental sulfur recovered by the SRU. This methodology maximizes the energy required to treat and remove sulfur.

For crude oil, the URM estimates the total sulfur content (by weight) in the crude oil purchased for the Facility, and the weight of the sulfur that will exit the Facility in the fuel oil blendstock produced by the SDA. To determine the amount of sulfur in the fuel oil blendstock, the URM estimates the amount of total crude oil sulfur contained in the residuum fraction processed in the SDA. The residuum sulfur content varies with the characteristics of each crude oil purchased for the Facility. The ratio of the sulfur contained in the residuum to the total amount of sulfur in the crude oil sulfur is entered as an input to the URM based on applicable assay data for each case (see Attachment 1). In general, the residuum contains from 20% to 60% of the total sulfur in the crude oil feedstock.

⁶ A long ton is 2,240 pounds.

TABLE A4.3-URM-6 GAS OIL DEMAND

	Barrels per Day
Gas Oil Gateway Unit Capacity at 100% Utilization	
FCC FHT	80,000
FCC	80,000
Hydrocracker	51,300
LNC	16,500
HNC	26,000
<i>Total Gas Oil Gateway Unit Demand at 100% of Capacity</i>	<i>253,800</i>
Gas Oil Supply from Crude and Refining	
Gas Oil from Crude Unit	(77,800)
DAO from SDA	(27,800)
Gas Oil Feed from FCC FHT to FCC	(73,600)
Gas oil from HNC	(2,400)
Gas Oil from FCC to Hydrocracker	(4,000)
Recycled Gas Oil from FCC to FCC FHT	(3,000)
<i>Total Gas Oil from Crude Imports and Facility Processing</i>	<i>(188,600)</i>
Gas Oil Import Volume	
TOTAL	65,200
<i>Low Sulfur (Sweet) Gas Oil (for FCC Operation)</i>	<i>4,000</i>
<i>High Sulfur (Sour) Gas Oil</i>	<i>61,200</i>

Note: Assuming (1) 100% gas oil unit and crude unit capacity use; and (2) crude oil with baseline period characteristics (see Table A4.3-URM-3) (barrels per day).

The URM then calculates the percentage of sulfur in the residuum that will exit the Facility in the fuel oil blendstock produced by the SDA and not further processed. Published information indicates that approximately 50% of the sulfur in the residuum will exit the Facility in the fuel oil blendstock,⁷ and the URM utilizes this ratio assumption for all cases (see Attachment 2).

⁷ Robert A Meyers, Handbook of Petroleum Refining Processes, Third Edition, (McGraw-Hill, 2004) p 10.27.

Figure A4.3-URM-2 illustrates the relationships between the crude unit, the SDA, and the rest of the Facility assuming that the crude oil feedstock contains 1000 long tons of sulfur and 50% of the total sulfur in the crude oil is contained in the residuum fraction. Under these assumptions, the URM calculates that 50% of the sulfur in the import crude oil (500 long tons) is contained in the fractions sent directly from the crude unit to other process units. The remaining 50% of the sulfur (500 long tons) is contained in the residuum and processed in the SDA. Half of the residuum sulfur content (250 long tons) will exit the refinery in the form of fuel oil blendstock produced by the SDA, and half (250 long tons) will be included in the gas oil produced by the SDA and sent to other Facility units for further processing. The total amount of sulfur processed by the Facility (not including the sulfur in the fuel oil blendstock) is 750 long tons. The URM assumes that all of the 750 long tons will be recovered by the SRU and will exit the Facility as elemental sulfur or sulfur product.

FIGURE A4.3-URM-2 ILLUSTRATION OF FACILITY SULFUR LOAD FROM CRUDE OIL FEEDSTOCK (1,000 LONG TONS OF SULFUR IN CRUDE OIL; 50% OF CRUDE OIL SULFUR IN RESIDUUM)

For gas oil, the URM assumes that all of the sulfur in purchased gas oil will be further processed within the Facility and exit as sulfur product from the SRU. The sulfur load attributable to purchased gas oil is calculated by estimating the total sulfur content by weight in sweet and sour gas oil based on the purchased volumes calculated by the URM.

Tables AQ-URM-7 and AQ-URM-8 illustrate the URM sulfur calculation methodology using model inputs that assume: (a) the crude oil feedstock has an API of approximately 31° and a sulfur content by weight of 2.75%; (b) purchased gas oil has a sulfur content by weight of 2.66%; (c) based on assay data, 19.44% of the crude oil feedstock consists of residuum and 55% of the total crude oil sulfur is contained in the residuum; and (d) the crude and gas oil gateway units are operated at 100% of capacity. As shown in Table A4.3-URM-7, the URM calculates that the Facility could process 257,200 b/d of crude oil, the permit maximum, without exceeding the NHT or the SDA throughput limits. In addition, approximately 57,000 b/d of purchased gas oil would be required to operate the gas oil gateway units at full capacity.

The total amount of sulfur introduced into the Facility is calculated using the crude and gas oil feedstock volumes, applicable crude and gas oil specific gravity data, and the percentage of sulfur by weight for each feedstock. Using this information, the URM calculates that the crude oil would contain approximately 962 lt/d of sulfur and that 55% of this amount (540 lt/d) will be routed to and processed in the SDA. The URM assumes that 50% of the sulfur processed in the SDA (265 lt/d) will exit the Facility in the fuel oil blendstock produced by the SDA without further processing.⁸ The remaining half of the sulfur in the SDA (265 lt/d) will be routed to other Facility process units in the gas oil produced by the SDA. As shown in Table A4.3-URM-8, the total amount of sulfur from crude oil processed in the Facility will be 698 lt/d (962-265 lt/d).

The amount of sulfur in the purchased gas oil is calculated by using the gas oil specific gravity factor (0.91) assumed in the URM (see Attachment 1) and the percentage of sulfur by weight in sour and sweet gas oil purchased by the Facility. Based on this information, the URM calculates that the purchased sour gas oil will contain approximately 201 lt/d, and the purchased sweet gas oil will contain about 1 lt/d, or a total of 202 lt/d. The total sulfur processed in the Facility from both purchased import crude and gas oil, less the sulfur in the fuel oil blendstock produced by the SDA, would be 900 lt/d (698 + 202 lt/d). Under these conditions, the SRU would operate at its full post-Modernization Project

⁸ From Robert A Meyers, Handbook of Petroleum Refining Processes, Third Edition, (McGraw-Hill, 2004) p 10.27.

TABLE A4.3-URM-7 ILLUSTRATION OF URM UNIT RATE CALCULATIONS

Unit	Unit Rate (b/d)
Crude Oil	257,200
Purchased Gas Oil	57,000

capacity and recover 900 lt/d from the Facility process units. The amount of sulfur the Facility processes varies with differences in the sulfur content, feedstock volumes, crude oil specific gravity, and the percentage of total crude oil sulfur contained in the residuum fraction for each case.

4.2.5 Post-Modernization Project Hydrogen Plant Production Calculation Methodology

Hydrogen is used within Facility process units for (a) the removal of sulfur and other naturally occurring impurities, and (b) "cracking" or otherwise changing

crude oil fractions. As shown in Figure A4.3-URM-1, hydrogen is supplied to several units and is produced by the Facility during the catalytic reforming process. Hydrogen is also recovered from various process gas streams and produced by the hydrogen plant for Facility use. Table A4.3-URM-9 lists the Facility process units that use hydrogen, and the hydrogen producing and recovery Facility activities analyzed in the URM.

The URM calculates post-Modernization Project hydrogen plant production for Facility use by subtracting the amount of hydrogen obtained from the Facility's catalytic reformers and process gas recovery from the total Facility hydrogen demand. Total Facility hydrogen demand is calculated by: (a) calculating per-barrel hydrogen demand for each hydrogen-using process unit, assuming crude and purchased sour gas oil has the same sulfur content as during the Baseline Period; and (b) adjusting the hydrogen demand as necessary to reflect increases or decreases from Baseline Period crude and purchased sour gas oil sulfur levels. The amount of hydrogen supplied by the production plant for Facility use is the difference between total Facility hydrogen demand adjusted for applicable sulfur content levels, and the amount of hydrogen available from other Facility operations.

Table A4.3-URM-10 illustrates the URM hydrogen plant production calculation methodology using the same model inputs in Tables AQ-URM-7 and AQ-URM-8, including a crude oil feedstock sulfur content of 2.75% and a purchased sour gas oil sulfur content of 2.66%. A per-barrel hydrogen demand factor for each of the Facility process units that use hydrogen was derived technical sources and Baseline Period operational data and integrated into the URM. Under Baseline Period conditions, for example, the NHT was estimated to use approximately 95 standard cubic feet (scf) of hydrogen per barrel and approximately 5.3 million scf per day (mmscfd) of hydrogen at a daily throughput of 56,200 b/d. The hydrocracker was estimated to use approximately 2,150 scf of hydrogen per barrel and approximately 110.3 mmscfd at a daily throughput of 51,300 b/d (see Attachment 2 for the hydrogen demand factors estimated for applicable units in the URM).

The URM adjusts the Facility's hydrogen demand by calculating the difference between the percentage of sulfur by weight in the crude oil (net of the sulfur that exits the Facility in the SDA fuel oil blendstock) and purchased gas oil compared with Baseline Period levels. If the sour gas oil content in a certain case is 2.5%, for example, the difference between the Baseline Period gas oil sulfur content level of 1.5% is +1.0%. Based on available technical information, approximately 100 scf per barrel per day is required to change the sulfur content of a barrel of

oil by 1% (M.D. Edgar, et. al., 1984).⁹ As a result, the URM assumes that processing gas oil with a sulfur content of 2.5% would require 100 scf per barrel more hydrogen than gas oil with a Baseline Period sulfur content of 1.5%.

⁹ The adjustment factor is consistent with estimates of theoretical hydrogen usage, that show that the amount of hydrogen required to remove one incremental percent

Table A4.3-URM-11 illustrates the URM hydrogen demand adjustment summarized in Table A4.3-URM-10 in more detail. Excluding the sulfur exiting the Facility from the SDA, the sulfur content in the Baseline Period crude oil blend was 1.26% by weight. The sulfur content in the crude oil analyzed in Table A4.3-URM-11 is 2.15% excluding the sulfur exiting the Facility from the SDA, an increase of 0.89% from Baseline Period levels. Based on this differential, the URM increases total Facility hydrogen demand by 21.6 mmscfd given a total import crude volume of 238,714 b/d to the Facility excluding the volume of fuel oil blendstock discharged from the SDA. The sulfur content in Baseline Period sour gas oil was 1.5% compared to the value of 2.66% assumed in AQ-URM-Table 11. Based on this differential, the URM increases total Facility hydrogen demand by 6.1 mmscfd utilizing the calculated purchased sour gas oil volume of 53,000 b/d (see Table A4.3-URM-8).

Including these adjustments, the URM calculates that the total Facility hydrogen demand will be 291 mmscfd (see Table A4.3-URM-10).

The URM solves for the amount of hydrogen that the hydrogen plant supplies to the Facility by comparing total demand to internally-generated Facility hydrogen supplies. The Facility produces hydrogen from two internal sources: (a) the catalytic reformers at an assumed post-Modernization Project rate of approximately 850 scf per barrel of throughput; and (b) hydrogen recovered from process gas in the pressure swing absorption unit. Based on information supplied by the Modernization Project applicant, the hydrogen content available for recovery from process gas using Baseline Period crude and gas oil is approximately 30 mmscfd. The URM also assumes 90% of the fuel gas hydrogen will be recovered under post-Modernization Project conditions for use in the Facility.¹⁰ Under the assumptions used in Tables AQ-URM-7 to AQ-URM-11, the

of sulfur per barrel would be 34-40 scf. This range was calculated via the following equation:

$$H = SG_{crude} \times \rho_{water} \times 42 \frac{gallons}{barrel} \times 1\%S \times \frac{1 lb-mol}{32.07 lb S} \times \frac{1 lb-mol S}{1 lb-mol H_2} \times \frac{1 scf}{0.0026412 lb-mol}$$

Where:

H = scf H₂/barrel/%Sulfur

SG_{crude} = Specific Gravity (ratio of a material's density to that of water) of crude oil; ranges from 0.8203-0.97 for crudes considered in this EIR (unitless)

ρ_{water} = density of water (8.3 lbs/gallon)

This assumes that it would take exactly one mole of hydrogen to remove one mole of sulfur. However, the hydrogen gas can be consumed in other chemical reactions, or simply may not react at all, requiring a greater amount of hydrogen than under ideal calculations.

¹⁰ The URM estimates the fuel gas hydrogen content by multiplying the per unit hydrogen demand prior to adjustment by 13%. This produces 30 mmscfd under post-

TABLE A4.3-URM-11 ILLUSTRATION OF FACILITY HYDROGEN DEMAND ADJUSTMENT

Crude Oil Hydrogen Demand Adjustment	
Sulfur in Crude Oil Excluding Fuel Oil Blendstock Produced by the SDA	2.15%
Baseline Period Sulfur in Crude Oil Net of SDA Fuel Oil Blendstock	1.26%
Difference from Baseline Period	0.89%
Hydrogen Demand Per Barrel Per Percent Sulfur Content by Weight (SCF)	100
Crude Oil Excluding the Fuel Oil Blendstock Produced by the SDA (b/d)	238,714
Crude Oil Sulfur Content Adjustment (mmscfd)	21.6
Gas Oil Hydrogen Demand Adjustment	
Sulfur in Sour Gas Oil	2.66%
Baseline Period Sour Gas Oil Sulfur Content	1.50%
Difference from Baseline Period	1.16%
Hydrogen Demand Per Barrel Per Percent Sulfur Content by Weight (SCF)	100
Sour Gas Oil (b/d)	53,000
Gas Oil Sulfur Content Adjustment (mmscfd)	6.1

reformers and process gas recovery process would generate 72.2 mmscfd of hydrogen for Facility use compared with a Facility demand of 291 mmscfd. The URM calculates the difference between the available internal Facility hydrogen supply and total Facility demand, or 218.8 mmscf (291-72.2 mmscf) and assumes that all of the difference in demand will be met by hydrogen supplied from the hydrogen plant. The total amount of hydrogen used in the Facility, and the hydrogen plant's level of production, will vary with the level of crude and gas oil sulfur content, crude and purchased gas oil feedstock volumes, the amount of sulfur in the fuel oil blendstock produced by the SDA that exits the Facility, and crude oil specific gravity applicable to each case.

Modernization Project, maximum use conditions assuming crude and purchased gas oil with the same characteristics as during the Baseline Period. The available hydrogen in fuel gas will vary with calculated unit throughputs and is scaled in all cases by the 13% factor derived from Baseline period data. As shown in Table 9, when applicable unit throughput rates are higher than the results obtained from using Baseline Period crude and gas oil, the amount of hydrogen recovered from fuel gas can be slightly higher (i.e., 34.18 mmscf) than 30 mmscf.

4.2.6 2011 Facility Data and URM Analysis Results

This section compares the URM gas oil purchase, unit rate, and sulfur and hydrogen production calculations with actual refinery operations in 2011. The Notice of Preparation for the Modernization Project was issued in 2011, and the prior 3 years of operational information was used to evaluate the Facility's existing annualized operations. After the URM was developed, one more year of annualized operational data became available for 2011.¹¹ The actual 2011 Facility operating data was compared with model calculations using 2011 inputs to evaluate the accuracy of the URM. As discussed above, the URM requires certain inputs to calculate unit rates, sulfur recovery by the SRU, hydrogen demand and total crude and purchased gas oil use. Table A4.3-URM-12 summarizes the URM crude oil inputs from 2011 operational data provided by the Modernization Project applicant.

TABLE A4.3-URM-12 2011 CRUDE OIL VOLUME, WEIGHT AND FRACTIONAL DATA INPUT TO THE URM

Crude Oil Utilization (b/d)	195,600
Crude Oil API Gravity (degrees)	34
Specific Gravity	0.855
Fraction (Boiling Point, °F)	Percent of Total Crude Oil
Butane and Lighter Fractions	2.09
Naphtha (55-290)	19.11
Kerosene (290-510)	22.46
Diesel (510-625)	11.30
Gas Oil (625-770)	13.17
Heavy Oil (770-1020)	17.37
Residuum (1020+)	14.51

The refinery utilized approximately 195,600 b/d of crude oil during 2011 with gravity of approximately 34° API. The fractional characteristics of the 2011 crude oil feedstock were estimated on the basis of applicable assay data.

¹¹ The Facility crude unit was not operated for portions of 2012 and 2013 due to a fire in August 2012. As a result, 2012 and 2013 do not reflect the Facility's typical annualized operations.

Table A4.3-URM-13 summarizes the sulfur content inputs for 2011 entered into the URM.

TABLE A4.3-URM-13 2011 SULFUR CONTENT DATA INPUT TO THE URM

Crude Oil Sulfur Content	1.50%
Sour Gas Oil Sulfur Content	1.50%
Sweet Gas Oil Sulfur Content	0.25%
Crude Oil Sulfur in Residuum Fraction Processed in SDA	50%

Based on crude oil blend summaries provided by the Modernization Project applicant, the sulfur content of the crude oil was estimated to be approximately 1.50% by weight in 2011. The sulfur content in 2011 gas oil purchased by the Facility was estimated on the basis of consultations with the Modernization Project applicant and was approximately 0.25% by weight for sweet gas oil and approximately 1.50% by weight for sour gas oil. Based on assay data, approximately 50% of the crude oil sulfur content was contained in the residuum processed by the SDA during 2011, approximately the same ratio as the Baseline Period.

Table A4.3-URM-14 summarizes the gas oil gateway unit utilization rates for 2011 that were input to the URM.

TABLE A4.3-URM-14 2011 GAS OIL GATEWAY UNIT THROUGHPUT DATA INPUT TO THE URM

Gas Oil Gateway Unit	2011 Utilization (b/d)	Percent of 2011 Permitted Capacity
FCC FHT	33,800	52%
Hydrocracker	44,500	87%
FCC	70,400	88%
RLOP Hydrocrackers		
<i>LNC – light neutral hydrocracker</i>	10,200	62%
<i>HNC – heavy neutral hydrocracker</i>	18,800	72%

Note: Totals rounded to nearest 100.

The percentage of available capacity for the five gas oil gateway units varied from 52% for the FCC FHT to 88% for the FCC. Based on information provided by the Modernization Project applicant, the Facility purchased approximated 48,000 b/d of gas oil, including 38,000 b/d of sweet and 10,000 b/d of sour gas oil.

The URM was used to calculate unit rates, sulfur recovery and hydrogen demand, and purchased gas oil for the Facility based on the 2011 inputs summarized in Tables AQ-URM-12 to AQ-URM-14. The analysis results are presented in Table A4.3-URM-15 and compared with the operational data for 2011. The shaded rows identify the six units (the crude unit and the five gas oil gateway units) that function as URM inputs. The unshaded rows are units or other refinery operational results that are calculated by the URM.

As shown in Table A4.3-URM-15, in almost all instances the URM results are higher, and therefore more conservative, than the 2011 data for each unit and Facility activity calculated by the model. The Facility's gas oil purchases, sulfur recovery, and hydrogen plant demand were all lower in 2011 than calculated by the URM. The average daily throughput in the crude unit vacuum column, NHT, catalytic reformers, pen/hex isomerization unit, JHT and DHT was also lower during the year than calculated by the URM. The model results were lower for only three units, including the GHT and the small polymerization unit which has negligible effect on total refinery activity. Model results were also approximately 2% lower for the SDA and within the range of assay data variability that can occur over a year. The URM sulfur recovery and hydrogen demand calculations were within 0.86% and 1.16% of the 2011 operational results. As a result, the URM provides a more conservative analysis of 2011 Facility activity compared with operational data for that year.

4.3 SUMMARY OF URM SCENARIOS

This section summarizes the URM scenarios that have been developed during the preparation of the Modernization Project EIR, including:

1. Eight scenarios that are representative of crude oil blends and gas oil that could be processed by the Facility under post-Project conditions assuming that proposed Modernization Project improvements have been completed and conservative 93% and 100% of crude and gas oil gateway unit capacity utilization rates;
2. Three scenarios that analyze potential Facility operations under future conditions assuming the proposed improvements have been completed, the use of crude oil that is much heavier, much lighter and that has a higher sulfur content than Baseline Period and the Modernization Project-related cases above;

TABLE A4.3-URM-15 URM RESULTS AND 2011 FACILITY DATA

	URM Results (b/d)	2011 Unit Rates (b/d)	2011 Unit Rate vs. URM Results (%)
Crude Oil	195,600	195,600	NA
Gas Oil	58,100	48,000	-21.04%
Total	253,700	243,600	-4.15%
Process Unit Throughput

<i>LNC – light neutral hydrocracker</i>	10,200	10,200	NA
<i>HNC – heavy neutral hydrocracker</i>	18,800	18,800	NA
Solvent De-Asphalting (SDA) Unit	28,400	29,000	2.07%
Sulfur Recovery Unit (SRU) (lt/day)	351	348	-0.86%
Hydrogen Plant Demand (mmscfd)	148	146.3	-1.16%

Note: Numbers rounded to nearest 100.

3. Two scenarios that analyze potential Facility operations under no-Modernization Project future conditions (i.e., no changes to the Facility related to the Modernization Project occur) assuming 93% and 100% of the crude and gas oil gateway unit capacity is utilized; and
4. Additional scenarios provided for informational purposes in Attachment 3 that analyze various crude oil blends that are highly unlikely or technically

infeasible to be used the Facility due to factors such as cost, availability, accessibility, fractional properties that are incompatible with the range of crudes that the Facility is designed to process, or chemical properties, such as excessive acidity that would damage certain Facility processing units.

4.3.1 Modernization Project-Related Cases

This section summarizes the URM analysis of a range of project cases that are representative of potential crude oil blends and gas oils that could be run by the refinery post-Modernization Project, and assumes that the Facility operates at 93% and 100% of the permitted capacity of the crude and gas oil gateway units and after the Modernization Project improvements have been completed. The analysis is conservative because the Facility utilized only 89% of the crude unit capacity on an average daily basis over the Baseline Period,¹² and refineries cannot practicably operate crude and gas oil processing units at 100% of capacity for more than short intervals of time.

Four representative crude blends were analyzed at both the 93% and 100% utilization levels, including:

1. A “project crude blend” case with a higher sulfur content than the Baseline Period blend (2.5% versus 1.58% during the Baseline Period) and an API gravity that is slightly lower than the Baseline Period (31.6° API versus 33.7° API during the Baseline Period);
2. A “lightest crude blend” case with the highest API that can achieve the specified 93% and 100% utilization rates without exceeding the NHT unit’s processing capacity;
3. A “heaviest crude blend” case with the lowest API that can achieve the specified 93% and 100% utilization rates without exceeding the SDA unit’s processing capacity; and
4. A “most sour crude blend” case that can achieve the specified 93% and 100% utilization rates and that would recover sulfur in an amount that approximates the maximum SRU limit of 900 lt/d that is part of the Modernization Project.

The crude oil blends that were used in each case were identified by considering a range of potential crude oil supplies, and optimizing the crude blends to meet the specific 93% and 100% Utilization scenarios and that contain sulfur in amounts consistent with the Modernization Project’s objective of increasing the

¹² As discussed in Attachment 5, on an average daily basis the Facility utilized 76% of the crude unit during 2011.

sulfur processing capacity of the Facility. Potential crude oil blends that generate significantly less sulfur than the Facility's current processing capacity of 600 lb/d, for example, could be used under current conditions and without upgrading the SRU and related facilities as proposed by the Modernization Project. Crude oils that, for reasons including cost, accessibility, reliability and chemistry (such as excessive acidity) that are highly unlikely or that cannot reliably be used by the Facility as currently configured were also not considered because such crudes are not representative of crude oil feedstocks that might be used under reasonably foreseeable post-Modernization Project operating conditions.

Table A4.3-URM-16 summarizes the crude oil blends used in the URM analysis of reasonably foreseeable future operations at 93% utilization of the crude and gas oil gateway unit capacity.

TABLE A4.3-URM-16 CRUDE OIL BLENDS, 93% CRUDE AND GAS OIL GATEWAY UNIT UTILIZATION (BARRELS PER DAY)

Crude Oil Source	Project Crude Blend	Lightest Crude Blend	Heaviest Crude Blend	Most Sour Crude Blend
Arab Light	96,910	-	180,100	-
Basrah	142,290	127,200	-	228,200
Bakken	-	112,000	-	-
Eocene	-	-	59,100	11,000
TOTAL	239,200	239,200	239,200	239,200

Note: All numbers rounded to 100.

As discussed in Section II, the URM requires several inputs, including the level of crude and gas oil gateway unit capacity utilization, and crude oil fractions and crude and gas oil sulfur content information based on assay data. Table A4.3-URM-17 summarizes the inputs used in the URM analysis of reasonably foreseeable future operations at 93% utilization of the crude and gas oil gateway unit capacity.

Table A4.3-URM-18 summarizes the amount of crude oil and purchased gas oil, and the average daily unit rates (b/d processed by each unit) for each of the four representative cases assuming 93% utilization of the crude and gas oil gateway unit capacity.

TABLE A4.3-URM-17 URM INPUTS, PROJECT-RELATED CASES, 93% CRUDE AND GAS OIL GATEWAY UNIT UTILIZATION

	Project Crude Blend	Lightest Crude Blend	Heaviest Crude Blend	Most Sour Crude Blend

Sulfur Recovery Unit (SRU)(lt/day)	749	587	758	834
Hydrogen Plant production (mmscfd)	197	178	202	205

Note: Numbers rounded to 100.

As shown in Table A4.3-URM-18, the crude and gas oil gateway units (the FCC, FCC FHT, hydrocracker, LNC and HNC) each operate at 93% of future utilization capacity (i.e., including Modernization Project-related capacity changes to the FCC FHT). The lightest crude blend case uses all of the capacity of the NHT (57,600 b/d). The heaviest and most sour crude blend cases use the full capacity

of the SDA (50,000 b/d). The lightest blend case generates the highest level of crude and purchased gas oil use, 305,500 b/d compared with project crude blend case crude and gas oil use of 292,900 b/d. Sulfur recovery ranges from 587 lt/d in the lightest crude blend case to 834 lt/d in the most sour crude blend case. The Facility's hydrogen supply from the hydrogen plant (i.e., net of hydrogen obtained from internal processing and recovered from gas fuel) ranges from 178 mmscfd in the lightest crude blend case to 205 mmscfd in the most sour crude blend case.

Table A4.3-URM-19 summarizes the crude oil blends used and Table A4.3-URM-20 summarizes the inputs used in the URM analysis of reasonably foreseeable future operations at 100% of the crude and gas oil gateway unit utilization capacity.

In certain cases, the crude oil blends that allow for Facility operations at 100% of the crude and gas oil gateway unit capacity are different than the comparable blends in the 93% utilization cases. The amount of heavier blends that the Facility can process, for example, can be constrained by the SDA processing capacity. The Facility can use a crude blend with a greater percentage of residuum at 93% utilization than at 100% utilization. As a result, the heaviest crude blend API at 93% utilization is 29.2° (see Table A4.3-URM-17) compared with 30.3° at 100% utilization (see Table A4.3-URM-20). Due to the lighter fraction processing limit of the NHT, the lightest crude blend API at 100% utilization is 35.0° compared with 35.3 at 93% utilization (see Table A4.3-URM-17)

Table A4.3-URM-21 summarizes the amount of crude oil and purchased gas oil, and the average daily unit rates (barrels per day processed by each unit) for each of the four reasonably foreseeable cases assuming 100% utilization of the crude and gas oil gateway unit capacity.

As shown in Table A4.3-URM-21, the crude and gas oil gateway units (the FCC, FCC FHT, hydrocracker, LNC and HNC) each operate at 100% of future utilization capacity (i.e., including Modernization Project-related capacity changes to the FCC FHT). The lightest crude blend case uses all of the capacity of the NHT (57,600 b/d). The heaviest and most sour crude blend cases use the full capacity of the SDA (50,000 b/d). The lightest blend case generates the highest level of crude and purchased gas oil use, 324,300 b/d compared with crude and purchased gas oil use of 315,200 b/d in the project blend crude case. Sulfur recovery ranges from 600 lt/d in the lightest crude blend case to 869 lt/d in the most sour crude blend case. The Facility's hydrogen supply from the hydrogen plant (i.e., net of hydrogen obtained from internal processing and recovered from gas fuel) ranges from 192 mmscfd in the lightest crude blend case to 217 mmscfd in the most sour crude blend case.

Note: Numbers rounded to nearest 100.

The URM analysis of the project, heavier, lighter and more sour crude cases at 93% and 100% of crude and gas oil gateway unit utilization capacity consider crude oil blends that range from 29.6° to 35.3°, crude oil sulfur content from 1.50% to 2.98% by weight, and total crude and purchased gas oil use of 284,900 b/d to 324,300 b/d (see Tables AQ-URM-17 to AQ-URM-18 and Tables AQ-URM-20 to AQ-URM-21). Emissions estimates for each of these cases have been prepared and are included in the Modernization Project EIR. To provide a conservative assessment, the EIR further analyzes each of these cases assuming that the hydrogen plant uses any excess production capacity above the Facility's demand as calculated by the URM and operates at 100% of proposed permitted utilization capacity. Health risk assessments have been prepared and are included in the EIR for the project crude blend and lightest crude blend cases assuming the hydrogen plant operates at 100% utilization, which is above the levels calculated by the URM for these cases.

4.3.2 Very Heavy, Very Light and Maximum Sulfur Cases

This section summarizes the URM analysis of very heavy, very light and maximum sulfur content crude cases. The purpose of this analysis is to show how the Facility processing units, the SRU and the hydrogen plant would operate in the event that the Facility used much heavier, much lighter and more sour crude oil than would occur under representative future conditions. As shown in Table A4.3-URM-22, each is based on a crude oil blend that facilitates the URM analysis of the operational consequences of processing very heavy, very light, and very sour crude oil.

TABLE A4.3-URM-22 CRUDE OIL BLEND, VERY HEAVY, VERY LIGHT, AND MAXIMUM SULFUR CASES (BARRELS PER DAY)

	Very Heavy	Very Light	Maximum Sulfur
Arab Light	-	-	39,200
Basrah	-	-	218,000
Bakken	-	199,300	-
Eocene	135,000	-	-
TOTAL	135,000	199,300	257,200

Note: Numbers rounded to nearest 100.

Table A4.3-URM-23 summarizes the inputs used in the URM analysis of the very heavy, very light and maximum sulfur crude cases. The API of the very heavy crude oil is approximately 18.3° and the API of the very light crude oil is approximately 41°. These crude blends are substantially heavier and lighter than

the average gravity of the Baseline Period crude blends (API=33.7°) and the representative project crude blend at 93% capacity (31.6°; see Table A4.3-URM-17). All three cases assume that the crude and gas oil gateway units will operate at 100% of capacity unless constrained by one or more Facility processing unit limits.

TABLE A4.3-URM-23 URM INPUTS, VERY HEAVY, VERY LIGHT, AND MAXIMUM SULFUR CASES

	Very Heavy	Very Light	Maximum Sulfur
Crude and Gas Oil Gateway Unit Capacity Utilization (%)	100%	100%	100%
Crude Oil Fractions (% Each Boiling Point Range from Assay Data, °F)			
Butane and Lighter Fractions	0.67	2.87	2.12

Alkylation Unit	27,700	27,700	27,700
Polymerization Unit	7,600	7,600	7,600
Hydrocracker	51,300	51,300	51,300
Richmond Lube Oil Plant (RLOP)			
<i>LNC – light neutral hydrocracker</i>	16,500	16,500	16,500
<i>LNF – light neutral hydrofinisher</i>	22,000	22,000	22,000
<i>HNC – heavy neutral hydrocracker</i>	26,000	26,000	26,000
<i>HNF – heavy neutral hydrofinisher</i>	12,000	12,000	12,000
Solvent De-Asphalting (SDA) Unit	50,000	13,500	50,000
Sulfur Recovery Unit (SRU)(lt/day)	891	376	900
Hydrogen Plant production (mmscfd)	228	167	219

Note: Numbers rounded to nearest 100.

The URM results for the very heavy case results show that the Facility is unable to utilize the full capacity of the crude unit (257,200 b/d) when the crude oil blend feedstock contains more than 50,000 b/d of residuum. All of the residuum that enters the Facility is processed by the SDA which, due to equipment limitations and other factors operates at an annual average throughput of 50,000 b/d, less than the current permitted capacity of 56,000 b/d. The project will lower the annual average throughput permit limits to 50,000 b/d. As shown in Table A4.3-URM-23, assay data indicates that Eocene crude oil contains approximately 37% of the residuum fraction by volume. The SDA processing limit would be reached for Eocene crude use of approximately 135,000 b/d. In general, the URM results indicate that the Facility cannot utilize the full capacity of the crude unit for any crude oil blend that contain more than approximately 19.44% residuum by volume. Crude oil blends that are significantly heavier than the representative project crude blend case (31.6°; see Tables AQ-URM-17 and AQ-URM-20) and the average Baseline Period crude blend (33.7° API) usually contain more than 19.44% of residuum by volume.

The very heavy crude case results also indicate that Facility processing of heavier crude blends with relatively high sulfur content would also tend to be constrained by the maximum SRU processing limit of 900 lt/d. As shown in Table A4.3-URM-23, Eocene crude oil has a comparatively high sulfur content of approximately 4.57% by weight. Even if Eocene crude oil contained less residuum, the Facility could not process more than 135,000 b/d without exceeding the SRU processing limit. The URM results indicate that the Facility's capacity to process high sulfur content and heavier crude would tend to be constrained by either or both the SDA and the SRU processing limits.

The URM results for the very light case show that the Facility is unable to utilize the full capacity of the crude unit (257,200 b/d) when the naphtha in the crude oil blend feedstock, plus internal refinery flows to the NHT, exceed 57,600 b/d. All of the naphtha that enters the Facility, and a small amount of naphtha produced by other Facility units, is processed by the NHT which has a maximum capacity of 57,600 b/d. As shown in Table A4.3-URM-23, assay data indicates that Bakken crude oil contains approximately 25.2% of the naphtha fraction by volume. The NHT processing limit would be reached for Bakken crude volumes of approximately 199,300 b/d plus internal Facility feeds to the unit.

The URM results for the maximum sulfur case analyze how the Facility would operate under future conditions in the event that the crude and gas oil feedstocks contain enough sulfur to fully load the SRU (result in 900 lt/d sulfur recovery), and when the crude and gas oil gateway units are run at full capacity.

This case assumes a slightly higher sour gas sulfur content than in the 100% capacity most sour crude blend case in Table A4.3-URM-21 (2.66% versus 2.25% by weight) to result in a sulfur recovery of 900 lt/d¹³ in the maximum sulfur case would not exceed the maximum capacity of the SDA or NHT, and the crude unit could be operated at the unit's 257,200 b/d capacity. The total crude and purchased gas oil used by the Facility would be 314,200 b/d, and 219 mmscf of hydrogen would be supplied to the Facility from the hydrogen plant.

Emissions estimates for the very heavy, very light and maximum sulfur cases summarized in Tables AQ-URM-22 and AQ-URM-24 have been prepared and are included in the Modernization Project EIR.

4.3.3 No-Modernization Project Cases at 93% and 100% Utilization

This section summarizes the URM analysis of Facility operations under no-Modernization Project future conditions and without upgrading the Facility's processing capacity, the hydrogen plant and other improvements proposed by the Modernization Project. The Baseline Period Facility operational results summarized in Table A4.3-URM-3 represent the 89% utilization case under no-Modernization Project conditions. Table A4.3-URM-25 summarizes the URM analysis results for Facility operations at 93% and 100% of crude and gas oil gateway unit capacity under no-Modernization Project conditions and using the Baseline Period crude blend (see Table A4.3-URM-2). The results show that the Facility operations would be constrained by the existing hydrogen plant's net hydrogen output (accounting for 94% output purity) of approximately 170.2 mmscfd. Due to insufficient hydrogen supplies, the FCC FHT and the hydrocracker could not be run at permitted capacity in the 100% utilization scenario, and the FCC FHT could not operate at full capacity in the 93% utilization scenario.¹⁴ As a result, under no-Modernization Project conditions and using the Baseline Period crude blend, the Facility could not process imported gas oil in sufficient amounts to operate the gas oil gateway units at 100% or 93% of utilization capacity.

¹³ The most sour crude blend case in Table A4.3-URM-21 results in the recovery of 869 lt/d of sulfur and a Facility demand from the hydrogen plant of 217 mmscfd. The slightly higher level of sulfur in sour gas oil assumed in the maximum sulfur case results in the recovery of 900 lt/d of sulfur and a Facility demand from the hydrogen plant of 219 mmscfd.

¹⁴ Under no-Modernization Project conditions, the FCC FHT capacity would remain at 65,000 b/d and not increase to 80,000 b/d as proposed by the Modernization Project. The Hydrocracker capacity of 51,300 b/d would not be modified by the Modernization Project.

TABLE A4.3-URM-25 URM ANALYSIS OF NO-PROJECT REFINERY OPERATIONS, 93% AND 100% OF CRUDE AND GAS OIL GATEWAY UNIT UTILIZATION

	100% Utilization	93% Utilization
Crude and Purchased Gas Oil Use (b/d)		
Crude Oil	257,200	239,200
Sweet Gas Oil	49,300	43,200
Sour Gas Oil	6,100	13,800
Total	312,600	296,200
Refinery Unit Rates (b/d)		
Crude Unit – Atmospheric Column	257,200	239,200
Crude Unit - Vacuum Column	104,600	97,300
NHT	55,300	51,500
Catalytic Reformers	49,100	47,400
Pen/Hex Isomerization Unit	28,300	26,600
JHT	68,200	63,300
DHT	33,400	31,200
FCC FHT	30,800	31,400
FCC	80,000	74,400
GHT	19,500	18,200
Alkylation Unit	26,800	25,800
Polymerization Unit	7,600	7,100
Hydrocracker	45,400	47,700
Richmond Lube Oil Plant (RLOP)		
<i>LNC – light neutral hydrocracker</i>	16,500	15,300

<i>HNC – heavy neutral hydrocracker</i>	26,000	24,200
<i>HNF – heavy neutral hydrofinisher</i>	12,000	11,200
Solvent De-Asphalting (SDA) Unit	38,600	35,900
Sulfur Recovery Unit (SRU)(lt/day)	438	424
Hydrogen Plant Production (mmscfd)	170	170

Note: Numbers rounded to nearest 100.

Emissions estimates have been prepared for these cases and are included in the Modernization Project EIR. The No-Modernization Project cases are considered in more detail in the Alternatives section of the Modernization Project EIR.

4.3.4 Limited Sulfur Scenarios at 93% and 100% Utilization

This section summarizes the URM analysis of Facility operations under future conditions that include the proposed Modernization Project improvements at 93% and 100% of the crude and gas oil gateway unit capacity except that the SRU would be limited to 750 lt/d. The crude oil blend used in both of these scenarios is the same as in the 100% and 93% utilization project crude blend cases summarized in Tables AQ-URM-16 and AQ-URM-19. Table A4.3-URM-26 summarizes the fractional properties and sulfur content information input for these cases, which are the same as for the 93% and 100% utilization project crude blend cases in Tables AQ-URM-17 and AQ-URM-19.

TABLE A4.3-URM-26 URM INPUTS FOR LIMITED SULFUR CASES, 100% AND 93% CRUDE AND GAS OIL GATEWAY UTILIZATION, SRU LIMITED TO 750 LT/D

	100% Utilization	93% Utilization
Crude Oil Fractions (% Each Boiling Point Range from Assay Data, °F)		
Butane and Lighter Fractions	1.93	1.93
Naphtha (55-290)	17.36	17.36
Kerosene (290-510)	21.11	21.11
Diesel (510-625)	10.62	10.62
Gas Oil (625-770)	12.58	12.58
Heavy Oil (770-1020)	18.11	18.11
Residuum (1020+)	18.3	18.3
Feedstock Input Characteristics (% Weight, Unless Otherwise Specified)		
Crude Oil API Gravity (degrees)	31.6	31.6
Crude Oil Specific Gravity	0.868	0.868
Crude Oil Sulfur Content	2.5	2.5
Sour Gas Oil Sulfur Content	2.25	2.25
Sweet Gas Oil Sulfur Content	0.25	0.25
Crude Oil Sulfur in Residuum Fraction Processed in SDA	55	55

Table A4.3-URM-27 summarizes the limited sulfur case analysis results. The reduced 750 lt/d SRU limit would constrain the full use of the crude unit capacity in the 100% case. As a result, only 205,000 b/d of crude oil could be used by the Facility. In contrast, as shown in the 100% utilization project crude blend case in Table A4.3-URM-21, the Facility could use up to 257,200 b/d of crude oil with the same fractional characteristics and sulfur content if the SRU capacity was 900 lt/d. Table A4.3-URM-27 also shows that the crude unit can be operated at 93% of capacity (and with the same unit throughputs summarized for the 93% utilization project crude blend case in Table A4.3-URM-18) because the gas oil gateway units would also be run at 93% of full capacity and less sulfur from gas oil would be brought into the Facility.

Emissions estimates have been prepared for these cases and are included in the Modernization Project EIR. The limited sulfur cases are considered in more detail in the Alternatives section of the Modernization Project EIR.

4.3.5 Other URM Cases

Several URM cases were also developed during the preparation of the Modernization Project EIR with assumed crude oil blends that are highly unlikely to or that cannot reliably be used by the Facility as currently configured, or that have relatively low sulfur contents and are not consistent with Modernization Project objectives. Summaries of 41 of these cases are presented for informational purposes in Attachment 3.

4.4 CONCLUSION

The URM is designed to calculate future refinery unit throughput rates based on potential post-Modernization Project use of crude oil with varying fractional characteristics, crude and gas oil with varying sulfur contents, and varying gas and crude oil import volumes. To provide a conservative assessment, the URM maximizes crude and gas oil inputs to the extent possible subject to applicable unit throughput capacity and permit limits. The URM calculations require that a set of input values be entered into the model that characterize the crude oil's fractional characteristics and weight, and the sulfur content of the crude and purchased gas oil (see Attachment 1). This information would be derived from the applicable assay data. Once the inputs have been entered, the URM calculates the resulting process unit throughput, sulfur recovery amount, and hydrogen plant production levels using the parameters listed in Attachment 2. The URM results were utilized to estimate Facility emissions under post-Modernization Project conditions as a result of the calculated process unit throughput rates for each scenario.

**TABLE A4.3-URM-27 URM ANALYSIS OF LIMITED SULFUR (750 LT/D SRU LIMIT)
CASES, 93% AND 100% OF CRUDE AND GAS AND GAS OIL
GATEWAY UNIT UTILIZATION**

	100% Utilization	93% Utilization
Crude and Purchased Gas Oil Use (b/d)		
Crude Oil	205,000	239,200
Sweet Gas Oil	4,000	3,700
Sour Gas Oil	76,900	50,000
Total	285,900	292,900
Refinery Unit Rates (b/d)		
Crude Unit – Atmospheric Column	205,000	239,200
Crude Unit – Vacuum Column	91,400	106,700
NHT	42,400	48,500
Catalytic Reformers	42,600	45,500
Pen/Hex Isomerization Unit	22,500	25,200
JHT	54,300	60,800
DHT	26,500	29,900
FCC	80,000	74,400
FCC FHT	80,000	74,400
GHT	19,500	18,200
Alkylation Unit	27,700	25,800
Polymerization Unit	7,600	7,100
Hydrocracker	51,300	47,700
Richmond Lube Oil Plant (RLOP)		
<i>LNC – light neutral hydrocracker</i>	16,500	15,300
<i>LNF – light neutral hydrofinisher</i>	22,000	20,500
<i>HNC – heavy neutral hydrocracker</i>	26,000	24,200
<i>HNF – heavy neutral hydrofinisher</i>	12,000	11,200
Solvent De-Asphalting (SDA) Unit	37,500	43,800
Sulfur Recovery Unit (SRU)(lt/day)	751	749
Hydrogen Plant production (mmscfd)	208	197

Note: Numbers rounded to nearest 100.

Notes:

1. Case in which gas oil gateway units operate at 100% capacity, but 100% crude unit capacity cannot be achieved due to exceedance of at least one processing unit throughput limit.
2. Case in which crude unit is limited to specified level.

Subject: Chevron Energy and Hydrogen Renewal Project, Richmond, Contra Costa County,
California. LSA Project #ENV1201

Dear Chairperson Cambra:

Per our email of November 22, 2013, please accept this letter in place of the letter dated November 19, 2013. The November 19 letter was sent in error and did not accurately describe the proposed project. Chevron is proposing modernization improvements to facilities within its refinery complex in Richmond, Contra Costa County, California. The original project proposed in 2005 involved: (1) Hydrogen Plant replacement; (2) Hydrogen Purity Improvements; (3) Power Plant Replacement; (4) Catalytic Reformer Replacement; and (5) Associated Infrastructure Modifications; and (6) Other New and Replacement Facilities (storage tanks, control building and central maintenance building). In July 2008, the City of Richmond (City) certified an environmental impact report (EIR) and issued conditional use and design review permits for the project. Construction of two components, the Hydrogen Plant replacement and the Hydrogen Purity Improvements (i.e. Sulfur Removal Improvements), commenced in 2008, but was halted in July 2009 when the Superior Court found the EIR to be insufficient. At that time, the construction of these two components was more than 50% complete.

Following an appeal by Chevron, the Court of Appeal found the EIR to be insufficient, and set aside the permits for the project. On March 14, 2011, the Superior Court issued a writ of mandate setting forth the issues to be addressed in a Revised EIR in order for the City to reconsider the permits for the project. Chevron's proposed Revised Project will complete only the Hydrogen Plant replacement and the Hydrogen Purity (Sulfur Removal) improvements. It will also include the associated equipment needed to tie the improvements into the Refinery. The Catalytic Reformer replacement, Power Plant replacement, and other new and replacement facilities that were part of the original project have been eliminated.

LSA Associates, Inc. is conducting a study to determine if the project might affect cultural resources. The project area is located in unsectioned land of the San Pablo land grant, as depicted on the accompanying portion of the USGS *San Quentin, Calif.*, USGS 7.5' topographic quadrangle.

Based on cultural resources record searches conducted at the Northwest Information Center at Sonoma State University and a review of the Sacred Lands File at the Native American Heritage Commission, there are no recorded Native American cultural resources within the project area that

will be affected by the project. Please notify us if you or your organization has any information or concerns about cultural resources within the project area. To reach us, please contact me at the address and telephone number above or via email (neal.kaptain@lsa-assoc.com). We look forward to hearing from you. Thank you.

Sincerely,

LSA ASSOCIATES, INC.

The November 19 letter was sent in error and did not accurately describe the proposed project. Chevron is proposing modernization improvements to facilities within its refinery complex in Richmond, Contra Costa County, California. The original project proposed in 2005 involved: (1) Hydrogen Plant replacement; (2) Hydrogen Purity Improvements; (3) Power Plant Replacement; (4) Catalytic Reformer Replacement; and (5) Associated Infrastructure Modifications; and (6) Other New and Replacement Facilities (storage tanks, control building and central maintenance building). In July 2008, the City of Richmond (City) certified an environmental impact report (EIR) and issued conditional use and design review permits for the project. Construction of two components, the Hydrogen Plant replacement and the Hydrogen Purity Improvements (i.e. Sulfur Removal Improvements), commenced in 2008, but was halted in July 2009 when the Superior Court found the EIR to be insufficient. At that time, the construction of these two components was more than 50% complete.

Following an appeal by Chevron, the Court of Appeal found the EIR to be insufficient, and set aside the permits for the project. On March 14, 2011, the Superior Court issued a writ of mandate setting forth the issues to be addressed in a Revised EIR in order for the City to reconsider the permits for the project. Chevron's proposed Revised Project will complete only the Hydrogen Plant replacement and the Hydrogen Purity (Sulfur Removal) improvements. It will also include the associated equipment needed to tie the improvements into the Refinery. The Catalytic Reformer replacement, Power Plant replacement, and other new and replacement facilities that were part of the original project have been eliminated.

LSA Associates, Inc. is conducting a study to determine if the project might affect cultural resources. The project area is located in unsectioned land of the San Pablo land grant, as depicted on the accompanying portion of the USGS *San Quentin, Calif.*, USGS 7.5' topographic quadrangle.

Based on cultural resources record searches conducted at the Northwest Information Center at Sonoma State University and a review of the Sacred Lands File at the Native American Heritage Commission, there are no recorded Native American cultural resources within the project area that

will be affected by the project. Please notify us if you or your organization has any information or concerns about cultural resources within the project area. To reach us, please contact me at the address and telephone number above or via email (neal.kaptain@lsa-assoc.com). We look forward to hearing from you. Thank you.

Sincerely,

LSA ASSOCIATES, INC.

Subject: Chevron Energy and Hydrogen Renewal Project, Richmond, Contra Costa County,
California. LSA Project #ENV1201

Dear Chairperson Zwierlein:

Per our email of November 22, 2013, please accept this letter in place of the letter dated November 19, 2013. The November 19 letter was sent in error and did not accurately describe the proposed project. Chevron is proposing modernization improvements to facilities within its refinery complex in Richmond, Contra Costa County, California. The original project proposed in 2005 involved: (1) Hydrogen Plant replacement; (2) Hydrogen Purity Improvements; (3) Power Plant Replacement; (4) Catalytic Reformer Replacement; and (5) Associated Infrastructure Modifications; and (6) Other New and Replacement Facilities (storage tanks, control building and central maintenance building). In July 2008, the City of Richmond (City) certified an environmental impact report (EIR) and issued conditional use and design review permits for the project. Construction of two components, the Hydrogen Plant replacement and the Hydrogen Purity Improvements (i.e. Sulfur Removal Improvements), commenced in 2008, but was halted in July 2009 when the Superior Court found the EIR to be insufficient. At that time, the construction of these two components was more than 50% complete.

Following an appeal by Chevron, the Court of Appeal found the EIR to be insufficient, and set aside the permits for the project. On March 14, 2011, the Superior Court issued a writ of mandate setting forth the issues to be addressed in a Revised EIR in order for the City to reconsider the permits for the project. Chevron's proposed Revised Project will complete only the Hydrogen Plant replacement and the Hydrogen Purity (Sulfur Removal) improvements. It will also include the associated equipment needed to tie the improvements into the Refinery. The Catalytic Reformer replacement, Power Plant replacement, and other new and replacement facilities that were part of the original project have been eliminated.

LSA Associates, Inc. is conducting a study to determine if the project might affect cultural resources. The project area is located in unsectioned land of the San Pablo land grant, as depicted on the accompanying portion of the USGS *San Quentin, Calif.*, USGS 7.5' topographic quadrangle.

Based on cultural resources record searches conducted at the Northwest Information Center at Sonoma State University and a review of the Sacred Lands File at the Native American Heritage Commission, there are no recorded Native American cultural resources within the project area that

will be affected by the project. Please notify us if you or your organization has any information or concerns about cultural resources within the project area. To reach us, please contact me at the address and telephone number above or via email (neal.kaptain@lsa-assoc.com). We look forward to hearing from you. Thank you.

Sincerely,

Native American Contact	Response
Jakki Kehl	On December 10, 2013, Ms. Kehl's voice mail box was full. LSA tried to make a follow-up call on January 15, 2014 but the voice mail box was still full. LSA was unable to make a follow-up contact.
Kathy Perez	In a November 30, 2013 email to LSA, Ms. Perez stated the following: <i>Although there seems to be no immediate concerns for cultural sensitivities. The project appear to be close to water source. This may or may not be an issue. It is the recommendation of the Tribe to have the project take precautions by having both a qualified archeological firm and native americans on borad.</i>
Linda Yamane	On December 10, 2013, LSA left a voice message for Ms. Yamane asking her to contact LSA if she has any comments or concerns regarding the project.
Irene Zwierlein	On December 10, 2013, LSA left a voice message for Chairperson Zwierlein asking her to contact LSA if she has any comments or concerns regarding the project.
Michelle Zimmer	During a December 10, 2013, telephone conversation, Ms. Zimmer stated the following: <i>The area is sensitive and all construction crews should be trained in cultural sensitivity. If needed, an archaeologist and Native American should monitor.</i>
Ann Marie Sayers	During a December 10, 2013, telephone conversation, Chairperson Sayers stated the following: <i>An archaeologist and Native American should monitor.</i>
Rosemary Cambra	During a December 10, 2013, telephone conversation, Chairperson Cambra stated that she would speak with the tribal archaeologist and provide a response.
Andrew Galvan	During a December 10, 2013, telephone conversation, Mr. Galvan stated that the cultural resources documentation should provide procedures to be followed if Native American cultural resources are identified.
Ramona Garibay	On December 10, 2013, LSA left a voice message for Representative Garibay asking her to contact LSA if she has any comments or concerns regarding the project.

Dear Ms. Perez,

LSA is conducting a cultural resources study of the Chevron Energy and Hydrogen Renewal Project, in the City of Richmond, Contra Costa County, California. Please review the attached letter describing the project and maps depicting the project area.

Please let us know if you have any questions or concerns.

Thank you very much,
Michael Hibma

APPENDIX 4.8

Greenhouse Gases

APPENDIX 4.8 - BASE

BASE: Greenhouse Gas Baseline

APPENDIX 4.8-BASE GREENHOUSE GAS BASELINE

1.1 DEFINITION OF 2008-2010 PERIOD AND BASELINE

This environmental impact report (EIR) evaluates existing (2008-2010 period) Facility emissions, Baseline Facility emissions, and Project emissions. For existing (2008-2010 period) emissions, a period of 2008-2010 was chosen because it is representative of actual Facility operations. Year 2011 was also reviewed and determined to be consistent with the 2008-2010 period, but is not included in the 2008-2010 period. As described earlier, Facility 2008-2010 period emissions are presented with both the annual Emissions Inventory (EI) compiled by the Bay Area Air Quality Management District (BAAQMD) (*Appendix 4.3-EI*) and the greenhouse gas emissions inventory submitted to California Air Resources Board (CARB) under the California Mandatory Reporting Rule for Greenhouse Gas Emissions (*Appendix 4.8-CEI*).

This section also contains a description of an adjusted Baseline consistent with the *Neighbors for Smart Rail v. Exposition Metro Line Construction Authority*, (2013) 57 Cal. 4th 439 (Smart Rail) decision. In that decision, the California Supreme Court stated that an EIR can always appropriately consider as an “existing conditions baseline” the physical condition existing at the time the EIR is prepared and/or the physical condition projected to exist when a project becomes operational. However, the court accepted that environmental conditions evolve over time and agreed that it was a reasonable exercise of lead agency discretion to predict, based on substantial evidence, environmental conditions that would exist when a project actually began operations. In this EIR, both the 2008-2010 period emissions and an adjusted baseline (Baseline) are presented and compared to the Project impacts.

Because some time has elapsed since 2010, this section also compares information from the 2008-2010 period to information from 2011, as available. As will be shown in this section, operations during the 2008-2010 period are similar to operations at the Facility in 2011. Operations during the 2008-2010 period are not reflective of operations during 2012 or 2013, however. On August 6, 2012, a fire occurred in the crude unit, which is further described in *Section 4.13, Public Safety*. This fire resulted in a shutdown of crude unit until its restart in April 2013. During the crude unit shutdown, the Facility continued to process gas oil and other feedstocks but did not process crude oil. Accordingly, during the nearly 7-month period when the crude unit was not operating, the Facility did

not operate in a manner similar to that which occurred during the 2008-2010 period. However, the California Environmental Quality Act (CEQA) recognizes that temporary curtailments are not representative of normal conditions and therefore do not change the baseline.¹ Further, short-term greenhouse gas emissions from accidental releases such as the fire at the crude unit would be unlikely to have global climate change impacts. This section of the EIR addresses only construction and operational greenhouse gas emissions and impacts from routine operations. Accident risks and public safety issues, including an evaluation of the air emissions from the August 2012 fire, are addressed in *Section 4.13, Public Safety*.

Greenhouse gas emissions from the period of 2008-2010 are the “existing conditions baseline” and are simply referred to as the “2008-2010 greenhouse gas emissions” in this EIR. 2008 to 2010 is referred to as the “2008-2010 period” or “2008-2010 baseline period” in this EIR. The adjusted baseline, which is also presented here, represents the conditions that would be expected to exist, taking into account changes in rules and regulations, as well as changes to the setting that would occur between the end of the 2008-2010 baseline period and the beginning of operations, anticipated to be in January 2016. This adjusted baseline will be referred to as the “Baseline” in this EIR. The emissions from the Baseline are expected to be lower than emissions during the 2008-2010 baseline period as a result of the implementation of rules and regulations designed to reduce emissions.

A number of changes are incorporated into the Baseline, including the following:

- **Equipment upgrades and changes** since the end of the 2008-2010 period and the proposed beginning of Project operation (January 2016).
- **Rule changes** scheduled to take effect prior to 2016 which mandate reductions of greenhouse gas emissions from mobile sources and electricity generation.

Emissions from the Facility are closely tied to Facility utilization. Greater utilization results in greater emissions from process units at the Facility, as they use more fuel to process more feedstock. Greater utilization also results in greater emissions from transportation (i.e., shipping, rail, and trucking) because of the greater quantity of materials that need to be shipped to and from the

¹ From *Communities for a Better Environment v. South Coast Air Quality Management District* (2010): "A temporary lull or spike in operations that happens to occur at the time environmental review for a new project begins should not depress or elevate the baseline."

Facility. Emissions from the Facility are also tied to the utilization of various process units. Higher sulfur feedstocks require greater use of the hydrogen plant and the sulfur recovery unit. Accordingly, these higher utilization rates translate into greater emissions, as is described in more detail in *Section 4.8.4.2, Refinery Operational Emissions*.

In order to better understand the impact of different types of feedstocks on emissions, a Unit Rate Model (URM), as further described in *Appendix 4.3-URM*, was prepared to estimate how the Facility's processing units could potentially be used under Project conditions. The URM generates estimates of the daily average throughput or production of various Facility process units in relation to: (1) the amount of crude and gas oil inputs into the Facility; (2) the American Petroleum Institute (API) gravity and fractional characteristics² of the crude oil inputs; and (3) the sulfur content of the crude and gas oil inputs. This section describes the greenhouse gas emissions that would result from the processing of crude and gas oil and also evaluates the impact of both higher sulfur and heavier and lighter feedstocks.

The City of Richmond team worked closely with the BAAQMD to develop the approach to 2008-2010 period and Baseline emissions. The direction provided by BAAQMD formed the basis of the technical methods described in this section and in *Section 4.3, Air Quality*.

1.2 EXISTING SETTING: ACTUAL EMISSIONS DURING 2008-2010 PERIOD

1.2.1 Facility Operation Emissions

Greenhouse gas emissions during the 2008-2010 period are presented based on both the BAAQMD EI and CARB reports. As shown in Table A4.8-BASE-1, CARB and BAAQMD greenhouse gas emissions inventory totals are similar for 3 years during the 2008-2010 period. The small differences in totals are due to the BAAQMD inventory relying on a different methodology than the CARB inventory to calculate greenhouse gas emissions associated with the hydrogen plant, and further, the BAAQMD inventory does not include sulfur recovery unit process greenhouse gas emissions or greenhouse gas emissions from sources that are exempt from BAAQMD permitting. Therefore, the BAAQMD annual emissions totals are smaller than those presented in the CARB inventory reports. CARB and

² As discussed in *Chapter 3, Project Description*, crude oil is input to the Facility and distilled in the crude unit into specific fractions of oil defined by boiling temperatures. The phrase "fractional characteristics" refers to the relative proportion of each fraction in the crude oil that enters the refinery crude unit.

BAAQMD greenhouse gas inventories for the year 2011 are included in this table to further indicate that the 2008-2010 period years are typical of operations and

**TABLE A4.8-BASE-1 2008-2010 FACILITY OPERATIONS GREENHOUSE GAS EMISSIONS
(BAAQMD EI AND CARB REPORTS)**

Year	BAAQMD EI (MT CO ₂ e/Year)	CARB Report (MT CO ₂ e/Year)
2008-2010 Period		
2008	4,060,366	4,798,282
2009	4,283,141	4,522,383
2010	4,226,040	4,511,882
2008-2010 Average	4,189,849	4,610,849
Non-2008-2010 Period		
2011	4,374,532	4,345,277

Note: This table presents refinery operational emissions only, and does not include shipping or other transportation-related emissions, or indirect emissions from electricity and water usage.

Sources: Appendix 4.3-EI; Chevron Data Transmittal #53A, 2013; Chevron Data Transmittal #53B, 2013; Chevron Data Transmittal #53C, 2013. Total Facility emissions reported to CARB for reporting year 2011 are publically available at: <http://www.arb.ca.gov/cc/reporting/ghg-rep/reported-data/ghg-reports.htm> (accessed November 11, 2013).

2011 emissions are typically similar to the 2008-2010 period; however, only years 2008-2010 are considered in the Baseline evaluation.³

Based on the CARB reports, the average annual direct greenhouse gas emissions during the 2008-2010 period for the Facility was 4,610,849 metric tonnes (MT) of carbon dioxide equivalent (CO₂e). This value does not include shipping and other transportation emissions which are addressed in the next few sections. Chevron has been reporting its annual greenhouse gas emissions to CARB since 2008 under the Mandatory Reporting Rule, which requires that certain large industrial facilities report their greenhouse gas emissions on an annual basis. Each reporting entity must certify under the penalty of perjury that the emissions statements are accurate. All CARB reports for facilities emitting greater than

³ 2012 and 2013 are not representative years for greenhouse gas emissions due to the August 2012 fire that damaged the crude unit. See *Section 4.3, Air Quality*, for a more complete description of why 2012 and 2013 are not representative years.

25,000 MT CO₂e must also be verified by an independent third party.⁴ Chevron's CARB reports for 2008-2010 are included in *Appendix 4.8-CEI*. Total Facility emissions reported to CARB for reporting year 2011 are publically available on CARB's website (CARB, 2013c). Chevron's CARB report for 2011 is also included in *Appendix 4.8-CEI* to indicate that 2011 emissions are only 6% lower demonstrating that the 2008-2010 period is representative of normal operating conditions.

Based on the BAAQMD EI, average annual greenhouse gas emissions during the 2008-2010 period are 4,189,849 MT CO₂e. The EI is prepared by the BAAQMD for permitted facilities. An emission inventory is an itemized list of emission estimates for sources of air pollution for a specified time period. The BAAQMD requires stationary sources of emissions, such as the Facility, to provide the BAAQMD with an annual update on the activity, such as throughput or firing rates, of sources at the Facility. The BAAQMD uses the annual update to calculate emissions of greenhouse gases from each source. This EI is then used to assess fees on sources of pollution based on how much pollution is emitted. Chevron submits an annual update for the Facility in which it provides information on the usage, or activity, of each source. The BAAQMD reviews that information and then uses that activity information to generate an annual emissions inventory, which is referred to as the BAAQMD EI. As described earlier, the BAAQMD EI does not include sulfur recovery unit process greenhouse gas emissions or greenhouse gas emissions from sources that are exempt from BAAQMD permitting. Therefore, the BAAQMD annual emissions totals are typically smaller than those presented the CARB inventory reports.

Also part of Facility operations are indirect emissions from water and electricity usage. These are "indirect" because the greenhouse gas emissions occur elsewhere, but are a result of the operations at the Facility. Emissions associated with water usage arise out of the sourcing, treatment, and distribution of water. Greenhouse gas emissions associated with water usage are calculated by multiplying the water usage (2,519 million gallons [Mgal] freshwater and 1,570 Mgal reclaimed water) (Chevron Data Transmittal #36I (Rev. #2), 2014) by the electricity intensity factor appropriate for Northern California (3.5 megawatt-hours [MWh]/Mgal) for freshwater and 2.1 MWh/Mgal for reclaimed water) (CEC,

⁴ While 2008 emissions were not required by CARB to undergo third-party verification, Chevron's CARB report for 2008 was verified. Third-party verification is a rigorous process that is closely monitored by CARB. Verifiers must undergo training and accreditation through CARB. Conflicts of interest between the verification body and the reporting entity must be cleared before any verification activities may commence.

2006; CAPCOA, 2010; Chevron Data Transmittal #51 (Rev #1), 2013)⁵ and the average of the CO₂ emission factors reported by Pacific Gas and Electric Company (PG&E) (553.7 lb/MWh) for the year's corresponding to the 2008-2010 period and the methane (CH₄) and nitrous oxide (N₂O) emission factors reported by CARB (PG&E, 2013; CARB, 2010).⁶ The 2008-2010 period indirect emissions associated with water usage for the Facility average 3,062 MT CO₂e per year.

Similarly emissions associated with electricity imported from off-site occur at the power plant where the electricity is generated.⁷ Emissions for electricity generation are typically through the combustion of fossil fuels. The greenhouse gas emissions are calculated by multiplying the imported electricity (84,776 MWh) (Chevron Data Transmittal #36I (Rev #2), 2014) by the emission factor for PG&E corresponding to the 2008-2010 period, described above. The 2008-2010 period indirect emissions associated with imported electricity at the Facility average 21,618 MT CO₂e per year.

1.2.2 Shipping Emissions

Emissions for shipping, trucks and rail were not included or analyzed in the 2008 EIR because the Project (both as originally proposed and as currently proposed) does not include any changes to the Facility's import or export capability. Nevertheless, because the EIR analyzes emissions based on reasonably foreseeable post-Project Utilization Scenarios (93% and 100%) that would constitute an increase over 2008-2010 period Facility utilization, and because transportation-related emissions are driven by Facility utilization, this EIR provides a baseline for transportation-related emissions, and *Appendices 4.3-SHP* and *4.3 AQ-TRANS* estimates Project transportation-related emissions.

⁵ As indicated in Chevron Data Transmittal #51 (Rev #1), 2013, no facility wastewater is processed by the East Bay Municipal Utility District. Energy associated with on-site water treatment is assumed to be accounted for under the stationary combustion and/or purchased electricity portion of the facility's greenhouse gas emissions inventory.

⁶ The CO₂ emission factor is the average of the 2008-2010 emission factors provided in Greenhouse Gas Emission Factors: Guidance for PG&E Customers (PG&E, 2013). These historical emission factors are from PG&E's third-party-verified greenhouse gas inventory submitted to the California Climate Action Registry or The Climate Registry. The CH₄ and N₂O emission factors are from the CARB Local Government Operations Protocol Table G.7. Emission factors for the most recent year (2007) were used. The CO₂e emission factor (557.4 pounds/MWh) was calculated based on the Intergovernmental Panel on Climate Change global warming potentials as provided in Local Government Operations Protocol Table E.1. The global warming potentials for CO₂, CH₄, and N₂O are 1, 21, and 310, respectively.

⁷ This is distinct from electricity generated on site. Emissions from electricity generated off site are already included in the facility's emissions inventory in its CARB reports.

Shipping emissions are not included in the BAAQMD EI or the CARB reports and are discussed here separately. As described in greater detail in *Section 4.3, Air Quality* and *Appendix 4.30AQ-SHP*, estimates of shipping emissions during the 2008-2010 period are based on throughput, ship equipment information, and emission factors provided by Chevron and verified by ENVIRON. The methodology used to develop the shipping emissions inventory from waterborne activities related to operations at the Long Wharf is described in detail in *Appendix 4.3-SHP* and a report prepared by Chevron's contractor, ICF. The calculation methodology used to develop the inventory are consistent with the design of other San Francisco Bay shipping emission inventories (ENVIRON, 2008; Moffitt & Nichols and ENVIRON, 2010a-d) with some exceptions associated with Project-specific aspects, CEQA considerations, and Department of Homeland Security considerations. ENVIRON helped direct and peer review the methods described in *Appendix 4.3-SHP*. ENVIRON also engaged in review of third-party sources of information to confirm information provided by Chevron in this report (e.g., evaluating online data that showed the amount of time required for tugs to maneuver ships and barges into and out of docks for a sampling of ship calls at the Richmond Long Wharf and evaluating Chevron's reported at berth time using public data available from the Marine Exchange). ENVIRON also performed calculations to verify the accuracy of this information. In addition, the methodologies used to estimate shipping emissions were developed in consultation with the BAAQMD. The 2008-2010 greenhouse gas emissions associated with shipping average 41,333 MT CO₂e per year. *Section 4.3, Air Quality*, contains additional details on shipping emissions.

1.2.3 Rail and On-Road Mobile Sources

Emissions associated with other modes of transportation associated with the operation of the Facility are not included in the BAAQMD EI or the CARB reports and are discussed here separately. These include transportation of feedstocks and finished products using rail, trucks, and pipelines. The transportation methods for the various feedstocks and products are as follows:

- Rail
 - Ammonia (exports)
 - Base oils (imports and exports)
 - Liquefied petroleum gases (imports and exports)
 - Lubricant additives (imports)
 - Lubricants (exports)
- Trucks
 - Base oils (imports and exports)

- Fuel additives (imports)

Greenhouse gas emissions associated with non-shipping transportation are roughly 9,969 MT CO₂e per year, or approximately 0.2% of the 2008-2010 period inventory. Hence, this category of greenhouse gas emissions is very small compared to emissions from Refinery Operations and shipping. Non-shipping transportation greenhouse gas emissions are estimated to increase by 12% if the Facility were operated at full utilization without the Project.⁸

Table A4.8-BASE-2 summarizes the 2008-2010 greenhouse gas emissions.

TABLE A4.8-BASE-2 2008-2010 GREENHOUSE GAS EMISSIONS

Year	2008-2010 Period (MT CO ₂ e/Year)
Facility	4,610,849
Electricity Usage	21,618
Water Usage	3,062
Shipping	41,333
Rail and On-Road Mobile	9,969
Total	4,686,831

1.3 BASELINE: CONDITIONS AS OF PROJECT OPERATIONAL START (JANUARY 2016)

Because new regulations and equipment changes are scheduled to be implemented before the January 2016 expected start date of the Modernization Project, and consistent with the Smart Rail decision, a Baseline representing January 2016 conditions will be used for evaluating the significance of Project-

⁸ A 12% increase was found by scaling the Baseline crude and gas oil throughputs at 89% and 100% utilization.

related greenhouse gas emissions and for ensuring that there is no net increase in greenhouse gas emissions.

The Baseline incorporates emission reduction measures that will be implemented by January 2016. There are 13 individual measures identified by Chevron that will have been implemented after the 2008-2010 period and before the anticipated Project start (January 2016) that are to be implemented independent of the Project (Chevron Data Transmittal #25 (Rev #1), 2014). These include measures that are designed to increase energy efficiency and process performance, thus reducing fuel and electricity usage. Reduced fuel consumption results in fewer direct greenhouse gas emissions from combustion, while reduced electricity usage results in fewer indirect greenhouse gas emissions emitted at the power plant.

In total, these measures will result in an annualized savings of 74,610 MT CO₂e. A listing of these measures along with their annualized greenhouse gas emission reductions is provided in Table A4.8-BASE-3. These measures include upgrading motors, improving computer process controls, changing equipment, repairs, insulation, improvement of catalyst performance, and improved monitoring and maintenance. Annual savings from each of these measures range from 30,400 MT CO₂e (improvement to cogeneration selective catalytic reduction catalyst performance and gas turbine) down to 10 MT CO₂e (upgrade of standard motors with premium efficiency motors).

Ten of the measures that Chevron has completed or has committed to have received rebates under the Statewide Customized Offering for Business program administered by Pacific Gas & Electric (PG&E) and overseen by the California Public Utilities Commission (CPUC). These measures constitute up to 70,610 MT CO₂e in annual greenhouse gas reductions or roughly 95% of the total emission reductions that the Facility will implement before 2016. This program creates incentives for energy efficiency projects by providing rebates on permanent capital improvement projects that demonstrate a real savings in energy. Energy savings from these 10 measures were verified by a third-party consultant that reviews the baseline and post-project energy use as part of a requirement of the program. Baseline energy usage is based on a few years of data; post-project energy usage is based on 6 months of data.

Regulations that would affect emissions levels from the 2008-2010 period to the Baseline (2016) include the Pavley vehicle standards (Pavley), the Low Carbon Fuel Standard (LCFS), and the Renewables Portfolio Standard (RPS). Pavley and the LCFS would affect non-shipping transportation emissions. As is described in more detail in *Appendix GHG-Regulatory*, implementation of the Pavley regulation

is expected to reduce greenhouse gas emissions from California passenger vehicles by about 30% in 2016 (CARB, 2013a), and implementation of the LCFS would reduce the carbon intensity of California’s transportation fuels by at least 10% by 2020 (CARB, 2013b). As will be discussed in this section, non-shipping transportation (rail and on-road mobile source) greenhouse gas emissions are very small (< 0.2%) compared to other Facility emissions. Therefore, changes due to Pavley and LCFS are very small. The RPS would affect emissions associated with electricity usage and requires retail sellers of electric services to increase procurement from eligible renewable resources to 33% of total retail sales by 2020. Therefore, the RPS would lower emissions associated with water usage and imported electricity usage. Emissions associated with electricity and water usage are very small compared to total 2008-2010 period emissions (roughly 0.5%). Therefore, changes in indirect greenhouse gas emissions due to the RPS are very small.

There are no regulatory requirements between the 2008-2010 period and 2016 that affect greenhouse gas emissions from rail transport or shipping. Other non-regulatory factors resulting in changes between the 2008-2010 period and Baseline emissions are described in the sections below.

1.3.1 Refinery Operation Emissions

The Baseline emissions are based primarily on the CARB report for the 2008-2010 period with adjustments made to account for anticipated emissions in 2016 prior to the commencement of Project operations (i.e., accounting for the 13 emission reduction measures that are independent of the Project). For refinery fuel gas combustion and natural gas combustion in the sulfur recovery unit, fuel volumes are used in conjunction with CARB Greenhouse Gas Reporting Regulation emission factors. The quantity of natural gas combusted in the sulfur recovery unit thermal oxidizer was provided directly from Chevron and used with CARB Greenhouse Gas Reporting emission factors. The calculation of the 2008-2010 period and Baseline refinery operational greenhouse gas emissions is described in more detail in *Appendix 4.8-GOP*.

TABLE A4.8-BASE-3 NON-PROJECT FACILITY MEASURES THAT REDUCE GREENHOUSE GAS EMISSIONS

Measure	Emission Reductions (MT CO ₂ e/Year)
Cogeneration Plant – Improvement to selective catalytic reduction catalyst performance and gas turbine resulting in refinery steam savings.	30,400

TABLE A4.8-BASE-3 NON-PROJECT FACILITY MEASURES THAT REDUCE GREENHOUSE GAS EMISSIONS

Measure	Emission Reductions (MT CO₂e/Year)
Cogeneration Plant – Installation of new deaerator feed water preheat coil in the heat recovery steam generators to recover additional waste heat from the gas turbine exhaust resulting in reduced usage of deaerator steam.	19,400
Crude Unit – Online isolation and cleaning of fouled heat exchanger resulting in decreased furnace fuel consumption.	11,300
Rheniformer 5 – Improve furnace heat transfer through use of coating, reducing furnace firing required to heat process stream.	6,700
Refinery Furnaces – Install new furnace analyzers for improved monitoring resulting in decreased furnace fuel consumption.	3,500
Naphtha Hydrotreating Unit – Install computer process control to improve naphtha hydrotreating unit F-410 furnace operation resulting in decreased furnace fuel consumption.	1,300
Refinery – Operation of diesel hydrotreater power recovery turbine resulting in electricity savings.	700
#1 Power Plant Boilers – Reduce usage of boilers through improved planning.	300
Refinery – Replace steam turbine in fluid catalytic cracker plant with electrical motor resulting in refinery steam savings.	300
Refinery – Install new piping and associated pumps and traps to recover hot condensate from steam traps that currently discharge to industrial drains resulting in refinery steam savings.	300
Refinery – Operation of taylor katalytic denitrifier power recovery turbine resulting in electricity savings.	200
Refinery – Install insulation on uninsulated steam piping to minimize heat loss resulting in refinery steam savings.	200
Refinery – Upgrade standard motors with a premium efficiency motors resulting in electricity savings.	10
TOTAL	74,610

Source: Chevron Data Transmittal #25 (Rev #1), 2014.

Indirect emissions associated with electricity and usage are adjusted by taking into account the reduced greenhouse gas intensity due to the RPS. Table A4.8-BASE-4 summarizes the Baseline greenhouse gas emissions.

TABLE A4.8-BASE-4 BASELINE: REFINERY GREENHOUSE GAS EMISSIONS

	Adjusted Baseline (MT CO₂e/Year)
Refinery	4,536,239
Electricity Usage	14,371
Water Usage	1,793
Total^a	4,552,403

Note: ^aHere and in tables throughout this EIR, summing the individual rows may result in a number slightly different than the value appearing in the Total row. Any differences are due to rounding.

Source: *Appendix 4.8-GOP*.

1.3.2 Shipping Emissions

The Baseline shipping emissions are slightly reduced compared to 2008-2010 period shipping emissions to account for expected fleet changes that would result in a change in greenhouse gas emissions from shipping sources by 2016. Between the 2008-2010 period and 2016, Chevron will replace or switch certain ships powered by gas or steam turbine engines to ships powered by diesel internal combustion engines, which will result in a decrease in greenhouse gas emissions. These technology changes and the resulting impact on shipping emissions are accounted for in the calculation of the Baseline emissions, described in more detail in *Appendix 4.3-SHP*. Other ship replacements and regulations detailed in *Section 4.3, Air Quality* do not affect greenhouse gas emissions. Besides the fleet change described above, no other changes were made to the calculation of the Baseline shipping emissions as compared to the 2008-2010 period shipping emissions.

Table A4.8-BASE-5 summarizes the Baseline greenhouse gas emissions associated with shipping.

TABLE A4.8-BASE-5 BASELINE: SHIPPING GREENHOUSE GAS EMISSIONS

	Baseline (MT CO₂e/Year)
Shipping	40,910

Source: *Appendix 4.3-SHP*.

1.3.3 Rail and On-Road Mobile Emissions

The Baseline rail and on-road mobile greenhouse gas emissions are adjusted from the 2008-2010 period emissions by taking into account Pavley vehicle standards, the LCFS, the 2016 fleet year mix (the mix of older and newer trucks assumed to be on the road in 2016), and the associated updated emission factors applicable for 2016. As described in more detail in the *Appendix 4.8-Regulatory* section that follows, the Pavley vehicle standards adopted under Assembly Bill 1493 apply to passenger vehicles and light-duty trucks used by Chevron employees and vendors making deliveries to the facility. The LCFS applies to California transportation fuels, including fuels used by heavy-duty trucks and locomotives. These regulations impose standards that reduce the greenhouse gas emissions associated with the operation of rail and on-road mobile sources.

The calculation of the Baseline rail and on-road mobile emissions is described in more detail in *Appendix 4.3-TRANS*.

Table A4.8-BASE-6 summarizes the Baseline greenhouse gas emissions associated with rail and on-road mobile emissions.

MOBILE GREENHOUSE GAS EMISSIONS**

	Baseline (MT CO₂e/Year)
Rail and On-Road Mobile	9,634

Source: *Appendix 4.3-SHP*.

1.3.4 Summary of Baseline Greenhouse Gas Emissions

Table A4.8-BASE-7 shows both the overall 2008-2010 period and the Baseline greenhouse gas emissions. The Baseline is based on the 2008-2010 period crude unit utilization rate of 89% and the 2008-2010 period blend of crude and gas oils, which have a sulfur content of 1.58% (crude oil) and 1.5% (gas oil) and API gravity of 33.7 (crude oil).

TABLE A4.8-BASE-7 2008-2010 AND BASELINE GREENHOUSE GAS EMISSIONS

Year	2008-2010 Period (MT CO₂e/Year)	Baseline (2016) (MT CO₂e/Year)
Refinery	4,610,849	4,536,239
Electricity Usage	21,618	14,371
Water Usage	3,062	1,793
Shipping	41,333	40,910

Subject: Refinery Modernization Project - Transmittal #53A - 2008 AB32 GHG Data

Hector,

This Transmittal #53A provides the 2008 AB32 Greenhouse Gas (GHG) Report and 2008 GHG emissions data for natural gas combustion at the SRU.

The 2008 GHG emissions from natural gas combustion at the SRU are 33,112 metric tons CO₂e.

Please let me know if you have any questions.

Best Regards,

Steven Yang

Supplemental Fee Regulation Submissions

No Supplemental Fee Regulation submissions exist for this facility and reporting period.

Fee regulation submission data are required only for those reporters subject to additional reporting for the GHG fee regulation.

Note: Data shown here are subject to change. The data may not have not undergone independent third party verification or ARB staff review. Where errors are discovered mechanisms are available to allow revisions to the data. For this reason subsequent reports may show different emissions or other data than that provided here.

Fee Regulation data are displayed only for those reporters subject to additional reporting for the GHG fee regulation.

Third party verification is not required for supplemental Fee Regulation submission data.

Facility Emissions Detailed Report: 2008

06/01/2011 18:36:29

A large, stylized number 4 is formed by a series of horizontal black bars. The bars are arranged in a grid-like pattern, with some bars being longer than others to create the shape of the digit. The bars are solid black and have a uniform thickness. The overall effect is a high-contrast, digital-style representation of the number 4.

Subject: Refinery Modernization Project - Transmittal #53B - 2009 AB32 GHG Data
Hector,

This Transmittal #53B provides the 2009 AB32 Greenhouse Gas (GHG) Report and 2008 GHG emissions data for natural gas combustion at the SRU.

The 2009 GHG emissions from natural gas combustion at the SRU are 31,902 metric tons CO₂e.

Please let me know if you have any questions.

Best Regards,

Steven Yang

[illegible]

Facility Emissions Detailed Report: 2009

12/01/2010 11:48:54

A large, stylized black letter 'H' is centered on a white background. The letter is constructed from horizontal bars of varying lengths. The left and right vertical stems are made of many short, stacked bars. The top and bottom horizontal crossbars are made of a single long bar spanning the width of the letter. The middle section, where the stems meet the crossbars, is filled with a dense stack of horizontal bars of varying lengths, creating a textured, almost solid appearance. The overall effect is a bold, graphic representation of the letter 'H'.

Subject: Refinery Modernization Project - Transmittal #53C - 2010 AB32 GHG Data

Hector,

This Transmittal #53C provides the 2010 AB32 Greenhouse Gas (GHG) Report and 2010 GHG emissions data for natural gas combustion at the SRU.

The 2010 GHG emissions from natural gas combustion at the SRU are 31,236 metric tons CO₂e.

Please let me know if you have any questions.

Best Regards,

Steven Yang

Supplemental Fee Regulation Submissions

Submission ID	Name	Reporting Level	Submission Type	Reporting Year	Submission Status	Status Date
8178	Chevron Products Company - Richmond Refinery, 94802	Facility	Supplemental Emissions (Fee Regulation Only)	2010	Certified - Unverified Data	05/26/2011

Note: Data shown here are subject to change. The data may not have not undergone independent third party verification or ARB staff review. Where errors are discovered mechanisms are available to allow revisions to the data. For this reason subsequent reports may show different emissions or other data than that provided here.

Fee Regulation data are displayed only for those reporters subject to additional reporting for the GHG fee regulation.

Third party verification is not required for supplemental Fee Regulation submission data.

TOTAL EMISSIONS: Chevron Products Company - Richmond Refinery, 94802

* All emission values are displayed in metric tons.

CO2 Biomass values not included in the CO2 Eq. sum.

The summed and supplemental values tables include data reported for the facility and associated units. This applies to the emissions and fuels tables.

Total Emissions Reporting Status: **Verified**

Summed Emissions Data	CO2 Eq.	CO2	CH4	N2O	CO2 Biomass	HFCs	SF6

Unit Information

Generating Unit Name	Cogeneration Plant at Richmond Refinery
ARB ID	101384-001
Unit Type	Cogeneration Primary Sector - Topping Cycle
Description	2 Alstom Gas Turbines/Vogt HRSG's - 104 MW nameplate capacity (52 MW each) 1 Dresser Rand steam turbine - 30.40 MW nameplate capacity
Nameplate Capacity (MW)	134.40 MW
Unit Operating Status	Operating
Reporting Year	2010
Reporting Period	01/01/2010 - 12/31/2010

TOTAL EMISSIONS: Cogeneration Plant at Richmond Refinery

* All emission values are displayed in metric tons.

CO2 Biomass values not included in the CO2 Eq. sum.

Verification Body Name	Ernst & Young
Verification Body Address	700 West Georgia Street. P.O. Box 10101 Vancouver, British Columbia V7Y1C7 Canada
Mandatory Verification Finding	Positive
Is the submitted report reasonably assured of being free of material misstatements?	Yes
Is the submitted emissions data report reasonably assured of being in conformance with the regulation?	Yes

APPENDIX 4.8 - CGRP

Greenhouse Gas Mitigation Programs Emission
Reduction Calculations

APPENDIX 4.8-CGRP

GREENHOUSE GAS MITIGATION PROGRAMS EMISSION REDUCTION CALCULATIONS

This appendix presents greenhouse gas emissions reduction and cost effectiveness calculations for the following Community Greenhouse Gas Reduction Program (CGRP) measures considered in the Chevron Refinery Modernization Project EIR:

- 1.1 Urban Forestry
- 1.2 Zero Waste Programs
- 1.3 Residential Energy Efficiency Rebate
- 1.4 Commercial Energy Efficiency Rebate
- 1.5 Residential Solar Rebate (Single-Family and Multi-Family)
- 1.6 Commercial Solar Rebate
- 1.7 Pedestrian and Bicycle Master Plans Implementation
- 1.8 Electric Vehicles
- 1.9 Ride Share/Green Transportation
- 1.10 Bicycle Program
- 1.11 Transit Access
- 1.12 Wetlands Creation
- 1.13 2-Mw Solar Project

This appendix also includes a discussion of the maximum potential greenhouse gas reductions, a hypothetical case for budget spread, and co-benefits of CGRP measures, as well as synergies with other greenhouse gas reduction policies adopted by the City of Richmond.

1.1 URBAN FORESTRY

Planting individual trees in city parks, in city rights-of-way, on residential property, and on commercial property would sequester carbon dioxide (CO₂). In addition, if trees provide shade to buildings, there can be additional energy savings from reduced air conditioning energy use. However, based on the low number of “cooling degree days”¹ in Richmond, it is unlikely that shading from trees would provide additional energy savings.

¹ A “cooling degree day” relates the average day’s temperature to the energy

1.1.1 Co-Benefits

Co-benefits of this measure include:

- Improved air quality²
- Stormwater runoff mitigation
- Reduced crime
- Improved aesthetics
- increased property values
- local job creation from required maintenance and planting activities

1.1.2 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-1 presents annual greenhouse gas savings from the Urban Forestry Program and associated costs. An average annual CO₂ reduction of 0.082 metric tonnes (MT) per tree was assumed based on data provided by the United States Department of Agriculture (USDA) Forest Service.³

Table A4.8-CGRP-18 presents a hypothetical case for a budget spread for all greenhouse gas reduction measures discussed in this appendix. It is discussed in more detail in *Section 1.15, Hypothetical Case for Budget Spread*. Table A4.8-CGRP-18 also includes an estimate of the maximum possible greenhouse gas reductions from each measure as well as year-by-year emission reductions from each measure.

Table A4.8-CGRP-18 presents year-by-year emission reductions from the Urban Forestry Program for up to 10 years. As additional trees are planted each year, the annual emissions reductions reflect trees planted in the current year as well as in all previous years.

Assuming a project lifetime of 25 years,⁴ the greenhouse gas cost effectiveness of the Urban Forestry measure would be \$58 per MT.

demands of air conditioning. The monthly total cooling degree day for Richmond obtained from the Western Regional Climate Center (WRCC), <http://www.wrcc.dri.edu/cgi-bin/cliMONTcdd.pl?ca7414>, accessed December 11, 2013.

² Trees such as redwood, deodar cedar, live oak, and oleander have been shown to reduce airborne concentrations of particulate matter and toxic air contaminants (BAAQMD, 2012).

³ Annual CO₂ reduction of 0.082 MT per tree based on the estimated reduction of 4.5 million short tons from CO₂ sequestration for 50 million trees planted (McPherson, 2008).

⁴ The California Air Resources Board (CARB) uses a 25-year crediting period for urban forest offset projects (CARB, 2011).

1.1.3 Monitoring

The City of Richmond would monitor and verify the program by performing periodic tree surveys. For each tree planted, the annual greenhouse gas emission reductions would be calculated as the number trees planted, multiplied by an annual greenhouse gas emission reduction factor, such as the factor presented above of 0.082 MT per tree.

1.1.4 Leveraging

There is no leveraging of costs for the Urban Forestry Program, although some of the costs may be offset by State funding. There may be potential funding opportunities through the State of California Department of Forestry and Fire Protection (CAL FIRE) Urban Forestry and Urban Greening Grant Programs.⁵

1.1.5 Economic Benefit

In addition to energy savings, the Urban Forestry Program would represent an economic benefit to the community. The Urban Forestry Program would create local jobs from required planting and maintenance activities. In addition, property values could potentially increase due to improved aesthetics.

1.1.6 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.14:

- **High** – Enhance Other Environmental Sustainability
- **Medium** – Create Local Jobs, Reduce Local Greenhouse Gas Emissions, Improve Community Health, Create Community Wealth & Resilience, Accurate Metric/Verifiable, Magnitude of Greenhouse Gas Reduction Available, Leveraging

1.1.7 Additional Note

There is literature that suggests that the afforestation projects in temperate climates may lead to localized warming that counteracts the carbon sequestration of planting trees. For example, the results of one study show that an afforestation project in temperate regions produces regional warming due to decreased albedo (i.e., reflectivity) while contributing to cooling the rest of the planet due to carbon sequestration, suggesting that afforestation may offer little

⁵ CAL FIRE Grant information for urban forests can be found here: http://www.fire.ca.gov/resource_mgt/resource_mgt_urbanforestry.php, accessed October 31, 2013.

to no benefit to climate change (Bala, 2007). Other studies have shown that afforestation in temperate climates merely reduces, but does not cancel out, the carbon storage benefit (Betts, 2000; Kirschbaum, 2011). However, an important caveat is that these studies on afforestation in temperate climates are focused on conventional forests, which are on a much larger scale of trees compared to the quantity that would be used in an urban forest project. Thus, any local warming effects from urban forestry projects can be assumed to be negligible. This is especially true in urban environments that the albedo is variable and generally defined by the materials that comprise the city (e.g., concrete, asphalt, and bricks) which already decrease the reflective ability. Snow cover also significantly impacts albedo. Areas that are not generally impacted by snow fall are less affected by the potential warming due to afforestation and are able to benefit more from urban trees (Kirschbaum, 2011).

1.2 ZERO WASTE PROGRAMS

Zero waste programs reduce the amount of greenhouse gas emissions generated at local landfills by encouraging Richmond businesses and residents to increase diversion of waste to recycling and compost. The programs under this measure would provide free indoor recycling bins and compost bins, outreach materials, cart stickers, technical assistance and multi-lingual trainings.

1.2.1 Co-Benefits

Co-benefits of this measure include:

- Improved green business practices.
- Encouraging Richmond residents to develop a zero-waste lifestyle.
- Local job creation from staff time required to process the additional recycling and compost loads.

1.2.2 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-2 presents an estimate of waste generated in Richmond on an annual basis. This estimate was based on the 10-year average of waste disposed within the jurisdiction of the West Contra Costa Integrated Waste Management Authority (WCCIMA) between 2000 and 2009 (199,799 tons) (CalRecycle, 2014).⁶ Based on the population of Richmond in comparison with the total population serviced by WCCIMA, it was assumed that 50% of the total waste disposed originated in Richmond. The current WCCIMA waste diversion rate of 52% was

⁶ WCCIMA's jurisdiction includes the Cities of El Cerrito, Hercules, Pinole, Richmond, and San Pablo; and Contra Costa County.

used to convert the amount of waste disposed to the amount of waste generated.⁷

Table A4.8-CGRP-3 presents greenhouse gas emission reductions when the diversion rate for waste generated in Richmond is increased from 52% to 74%. Emission reductions were calculated following the methodology in the California Emissions Estimator Model (CalEEMod) User's Guide.⁸ The amount of each degradable waste type disposed in Richmond was estimated based on the total waste disposal rate and waste composition information for California waste streams (CIWMB, 2009).⁹ The amount of methane and CO₂ generated from each waste type was calculated based on the fraction of degradable organic carbon (DOC, the degradable anaerobic carbon fraction (DANF) , and the assumption that half of the anaerobic carbon is methane (CH₄) and the other half is CO₂ (IPCC, 2006; CARB, 2010).^{10,11} The amount of methane and CO₂ emitted was calculated by assuming 75% of the landfill gas emitted is collected by a landfill gas collection system, 98% of the landfill gas collected is destroyed, and 10% of the methane generated is oxidized to CO₂ as it rises through the landfill.¹² The total estimated reduction in greenhouse gas emissions from the diversion rate increase is 21,838 metric tonnes of carbon dioxide equivalents (MT CO₂e) per year.

Table A4.8-CGRP-18 presents year-by-year emissions reductions from zero waste programs. As the diversion rate is increased each year, the annual emissions reductions also increase.

⁷ The current diversion rate is provided by City of Richmond.

⁸ CalEEMod is a land use emissions estimation model that calculates emissions associated with energy, water, transportation, and waste for land use projects and is widely used by California air districts for California Environmental Quality Act (CEQA) projects. The waste emissions module calculates the greenhouse gas emissions associated with the decomposition of waste into methane and the generation of carbon dioxide from combustion of methane. This methodology is similar to that used by the Intergovernmental Panel on Climate Change (IPCC) in its 2006 Guideline for National Greenhouse Gas Inventories.

CalEEMod and calculation methodology is available online at:
<http://www.caleemod.com> (accessed October 9, 2013).

California waste composition information obtained from the California Integrated Waste Management Board (CIWMB).

¹⁰ DOC data obtained from Intergovernmental Panel on Climate Change (IPCC) Guidelines.

¹¹ DANF data is based on California Air Resources Board (CARB) Local Government Operations Protocol, V1.1.

¹² Landfill gas collection, destruction, and oxidation efficiencies are based on CalEEMod default values.

The estimated cost to run zero waste programs is \$200,000 per year, or \$2,000,000 over 10 years. Annual project costs can be broken down to the following:

Component	Cost (\$)
Free indoor recycling containers for businesses	\$50,000
Free recycling containers for residents	\$25,000
Posters and cart stickers for businesses and residents	\$50,000
Mailers to businesses and residents	\$25,000
Technical Assistance Consulting	\$50,000
Total	\$200,000

Notes: Costs provided by City of Richmond.

Many cities stipulate a cost limit target in their service contracts to reach their diversion goals. For example, the City of San Francisco has a goal of \$30 per ton of additional waste diverted. Given the City of Richmond's most recent figure of waste disposal (110,000 tons for 2012 corresponding to a 52% diversion rate) and its diversion goal of 74%, the quantity of additional diverted waste would be roughly 50,000 tons. At a cost limit target of \$30 per ton, this would represent a \$1,500,000 cost limit. This is comparable to the proposed \$2,000,000 to be spent on the City of Richmond program.

Assuming a project lifetime of 25 years, the carbon reduction effectiveness of the zero waste programs measure would be \$4 per ton.

1.2.3 Monitoring

The City of Richmond would monitor and verify the program by tracking total disposal rates and diversion rates. The annual greenhouse gas emission reductions would be calculated using methane and CO₂ generation rates for the different degradable waste types diverted, using the method described above.

1.2.4 Leveraging

There is no leveraging of costs for the zero waste program.

1.2.5 Economic Benefit

In addition to energy savings, the zero waste program would represent an economic benefit to the community. The zero waste program would create local

jobs from the staff time required to process the additional recycling and compost loads.

1.2.6 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.13:

- **High** – None
- **Medium** – Create Local Jobs, Reduce Local Greenhouse Gas Emissions, Enhance Other Environmental Sustainability, Accurate Metric/Verifiable, Magnitude of Greenhouse Gas Reduction Available, Leveraging
- **Not applicable** – Improve Community Health, Create Community Wealth & Resilience

1.3 RESIDENTIAL ENERGY EFFICIENCY REBATE

The residential energy efficiency rebate program reduces energy consumption in Richmond by providing home performance energy efficiency rebates to residents who employ Richmond contractors or RichmondBUILD graduates to perform retrofit work. Energy efficiency projects include installation of new windows and frames, insulation, weather-stripping, plugging gaskets, and programmable thermostats.

1.3.1 Co-Benefits

Co-benefits of this measure include:

- Local job creation
- Improved indoor air quality
- Improved comfort and durability of homes
- Fewer natural resources used to produce energy at power plants
- Reduced energy costs for residents
- Additional money spent in the community

1.3.2 Electricity Emission Factors

There are two major electricity providers serving the City of Richmond: Marin Clean Energy (MCE) and Pacific Gas & Electric (PG&E). PG&E is the only natural gas provider to the City. The greenhouse gas electricity emission factor used in this study represents the average of the PG&E and MCE greenhouse gas emission factors, weighted to reflect the percentage of customers in Richmond served by either utility. The PG&E electricity emission is calculated using the California

Public Utilities Commission (CPUC) Greenhouse Gas Calculator, which factors in projected GHG reductions under the Global Warming Solutions Act of 2006 ("AB32"). MCE provides low carbon intensity electricity under its Light Green program with an emission factor of 0.389 pounds carbon dioxide equivalents (CO₂e) per kilowatt-hour (kWh) in their reports to the California Climate Action Registry (CCAR) (CCAR, 2013). A greenhouse gas electricity emission factor for PG&E was calculated based on (1) 2016 CO₂ emission factor provided by PG&E in its April 2013 report "Greenhouse Gas Emission Factors: Guidance for PG&E Customers;" and (2) CH₄ and nitrous oxide (N₂O) emission factors taken from the CARB Local Government Operations Protocol (LGOP) (PG&E, 2013a; CARB, 2010). Global warming potentials (GWPs) for CH₄ and N₂O were taken from the U.S. Environmental Protection Agency (EPA) Mandatory Greenhouse Gas Reporting Rule (MRR) (EPA, 2012). The CH₄ and N₂O emission factors were multiplied by their respective GWPs to obtain CO₂e emission factors, then added to the PG&E CO₂ emission factor to obtain a PG&E greenhouse gas emission factor of 0.374 pounds CO₂e/kWh. In the City of Richmond, 84% of end users receive their electricity from MCE and 16% receive their electricity from PG&E (Kudo, 2013). The resulting weighted greenhouse gas electricity emission factor used in this study is 0.387 pounds CO₂e/kWh. The calculation is shown in Table A4.8-CGRP-19.

A greenhouse gas emission factor for natural gas was calculated based on (1) CO₂ emission factors used in PG&E Energy Overview Reports for the City of Richmond, and (2) CH₄ and N₂O emission factors taken from the EPA MRR (PG&E, 2013b; EPA, 2012).¹³ CH₄ and N₂O emissions were multiplied by their respective GWPs to obtain CO₂e emissions, then added to the CO₂e emission factor to obtain a greenhouse gas natural gas emission factor of 11.7 pounds CO₂e/therm. This is comparable to the greenhouse gas emission factor based on the EPA MRR.

1.3.3 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-4 presents estimated greenhouse gas emission reductions from the residential energy efficiency program. The program goal is to reduce energy consumption in existing homes by 40% (CEC, 2013a).¹⁴ Electricity and natural gas savings per percent reduction in energy consumption were calculated based on program data for home upgrade projects conducted in the City of Richmond

¹³ The average of CO₂ emission factors in reports dated between 2009 and 2011 was used.

¹⁴ The 40% reduction goal is consistent with California Energy Commission (CEC) strategy. This reduction goal is close to what had been achieved in past energy efficiency programs in Richmond.

under the PG&E Energy Upgrade California (EUC) program.¹⁵ These ratios were calculated for each individual project, then averaged over all projects to obtain estimated electricity savings of 12.3 kWh/% reduction and natural gas savings of 8.5 therms/% reduction. These ratios were multiplied by the 40% reduction goal to obtain average savings of 494 kWh and 338 therms per home retrofit, respectively. The corresponding emission reductions were calculated using the emission factors presented in Table A4.8-CGRP-19. The estimated annual greenhouse gas reduction is 1.9 MT per household.

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the residential energy efficiency program. The annual emissions reductions for each year reflect cumulative reductions from retrofits completed in the current year as well as in all previous years.

The City is proposing a \$2,000 rebate to homeowners under this program. For lower income qualifying residents (80% Area Medium Income [AMI]), the City will propose to offer a \$4,000 rebate. Assuming a project lifetime of 30 years (CEC, 2011),¹⁶ the greenhouse gas reduction cost effectiveness of the residential energy efficiency Rebate would be \$35 per MT CO₂e for households above 80% AMI and \$71 per MT CO₂e for households below 80% AMI. These cost effectiveness values are comparable to those calculated based on MEA's energy efficiency programs for multi-family homes and also to that estimated for the City of San Diego's Climate Action Plan (MEA, 2012; City of San Diego, 2012).^{17,18}

1.3.4 Monitoring

The City of Richmond would monitor and verify the program by tracking natural gas and electricity usage on an annual basis before and after project implementation. MCE currently has the resources to assist with this effort. The

¹⁵ Based on program data for residential projects implemented in the City of Richmond under the EUC Whole House program between December 2010 and May 2013. Program data obtained from Build It Green in May 2013.

¹⁶ The California Energy Commission (CEC) uses 30 years for life-cycle cost analysis for residential building envelope energy efficiency measures.

¹⁷ For a total program budget of \$860,971, MEA estimates an annual electricity savings of 822,709 kWh and natural gas savings of 46,864 therms. Incorporating the emission factors developed for Richmond, this results in a greenhouse gas savings of 399 MT per year. Assuming a 30-year project lifetime consistent with CEC guidance, this results in a cost effectiveness of roughly \$70 per MT CO₂e.

¹⁸ The City of San Diego Climate Mitigation and Adaptation Plan assumes the cost of a commercial retrofit for a single-family home to be \$13,000 resulting in a 30% energy reduction. When accounting for that the cost effectiveness for the City of Richmond program only accounts for the Chevron rebate amount (and not the entire cost of the retrofit) and the 30-year lifetime of the energy upgrade, the cost effectiveness values are similar.

annual greenhouse gas emission reductions would be calculated using natural gas and electricity emission factors, such as the ones presented in Table A4.8-CGRP-19.

1.3.5 Leveraging

The total cost to reduce household energy consumption by 40% is \$8,000, based on information supplied by Richmond's building performance contractor AHE. This cost would be shared by homeowners. After the proposed rebate, the resulting cost to homeowners would be \$4,000. For lower income qualifying residents (80% AMI), the resulting cost would be \$2,000.

1.3.6 Economic Benefit

In addition to energy savings, the residential energy efficiency rebate program would represent an economic benefit to participants. As presented in Table A4.8-CGRP-4, a 40% reduction in energy corresponds to annual energy savings of 494 kWh per home and 338 therms per home. Using current PG&E electricity and natural gas rates of \$0.14 per kWh and \$1.15 per therm, respectively, this corresponds to an annual savings of \$458 per home.^{19,20}

As a secondary benefit, the residential energy efficiency rebate program would create jobs by (1) employing Richmond contractors and RichmondBUILD graduates to perform retrofit work; and (2) increasing spending within the community due to energy savings.

1.3.6.1 Jobs Created from Retrofit Work

An average cost to perform retrofit work per percent energy savings was calculated based on program data for home upgrade projects conducted in the City of Richmond under the PG&E Energy Upgrade California (EUC) program.²¹ The ratio of the project cost to the percent reduction in energy consumption achieved was averaged over all projects to obtain an average cost of \$414 per percent energy reduction. The average cost to complete a retrofit resulting in a 40% reduction would be \$8,000 per home. The corresponding jobs metric would

¹⁹ Electricity rate used is the average of Tier 1/2 PG&E electricity rates between May and August 2013.

²⁰ Natural gas rate use is the average of PG&E base and excess natural gas rates for 2013.

²¹ Based on program data for residential projects implemented in the City of Richmond under the EUC Whole House program between December 2010 and May 2013. Program data obtained from Build It Green in May 2013.

be 0.15 job-years (annual full-time equivalent) created per home retrofitted (BEA, 2010a, 2010b).^{22,23}

1.3.6.2 Monetary Benefit to Community

Assuming customers would spend 90% of energy savings within the local community, the annual return to the community would be \$412 per home (BEA, 2013; US DOT, 2009).^{24,25} The corresponding jobs metric would be 0.005 jobs (annual full-time equivalent) created per home retrofitted (BEA, 2010a; BEA, 2010b).^{26,27}

The jobs metric would be the jobs created from retrofit work, 0.15 job-years (annual full-time equivalent) per home retrofitted.

1.3.7 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.13:

- **High** – Create Community Wealth & Resilience (Low Income only), Magnitude of GHG Reduction Available
- **Medium** – Create Local Jobs, Reduce Local Greenhouse Gas Emissions, Improve Community Health, Create Community Wealth & Resilience (Any Income), Enhance Other Environmental Sustainability, Accurate Metric/Verifiable, Leveraging

1.4 COMMERCIAL ENERGY EFFICIENCY REBATE

The commercial energy efficiency program reduces energy consumption in Richmond by providing energy efficiency rebates to businesses that employ Richmond contractors or RichmondBUILD graduates for building retrofits.

²² Assumes 9.66 job-years are created per million dollars spent.

²³ Assumes 95% of jobs created are full-time equivalent jobs.

²⁴ The assumption that 10% of income is saved is meant to be a conservative assumption. In July 2013, the national saving rate was 4.4%.

²⁵ The assumption that all spending will be within the local community is based on the 2009 overall average trip distance for the State of California of 8.79 miles, which means that all trips originating from Richmond would be within the boundary of Contra Costa County.

²⁶ Assumes 13.5 jobs are created per million dollars spent.

²⁷ Assumes 85% of jobs created are full-time equivalent jobs.

1.4.1 Co-Benefits

Co-benefits of this measure include:

- Local job creation
- Increased safety through improved lighting
- Fewer natural resources used to produce energy at power plants

1.4.2 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-5 presents greenhouse gas emission reductions from commercial energy efficiency improvements. These improvements could reduce the commercial sector's energy consumption by as much as 50% (CPUC, 2011).²⁸ The program would provide rebates for reduced energy consumption at rates of \$1 per therm and \$0.14 per kWh (EBEW, 2013).²⁹ For illustrative purposes, assuming an annual program budget of \$360,000 and an even divide between natural gas and electricity savings (i.e., therms saved = kWh saved), the annual greenhouse gas reduction would be 1,735 MT. Assuming a project lifetime of 30 years, consistent with CEC guidance (CEC, 2011),³⁰ the greenhouse reduction effectiveness of the commercial energy efficiency incentive would be \$7/MT CO₂e.

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the commercial energy efficiency rebate program. The annual emissions reductions for each year reflect cumulative reductions from retrofits completed in the current year as well as in all previous years.

1.4.3 Monitoring

The City of Richmond would monitor and verify the program by tracking natural gas and electricity usage on an annual basis before and after project implementation. MCE currently has the resources to assist with this effort. The annual greenhouse gas emission reductions would be calculated using natural gas and electricity emission factors, such as the ones presented in Table A4.8-CGRP-19.

1.4.4 Leveraging

There is no leveraging of costs for the commercial energy efficiency program.

²⁸ Based on the California Public Utilities Commission (CPUC) goal to convert 50% of existing commercial buildings to zero net energy buildings by 2030.

²⁹ Based on incentive from East Bay Energy Watch.

³⁰ The California Energy Commission (CEC) uses 30 years for life-cycle cost analysis for residential building envelope energy efficiency measures.

1.4.5 Economic Benefit

In addition to energy savings, the commercial energy efficiency program would create jobs by employing Richmond contractors and RichmondBUILD graduates. The number of jobs created was estimated by assuming businesses would spend twice as much as the amount of rebates provided on retrofit contracting work. The corresponding jobs metric would be 6.6 job-years (annual full-time equivalent) created each year, or 66 job-years created after 10 years (BEA, 2010a, 2010b).^{31,32,33}

1.4.6 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.13:

- **High** – Magnitude of Greenhouse Gas Reduction Available
- **Medium** – Create Local Jobs, Reduce Local Greenhouse Gas Emissions, Create Community Wealth & Resilience, Enhance Other Environmental Sustainability, Accurate Metric/Verifiable, Leveraging
- **Not applicable** – Improve Community Health

1.5 RESIDENTIAL SOLAR REBATE (SINGLE-FAMILY AND MULTI-FAMILY)

The residential solar rebate program reduces energy consumption in Richmond by providing solar rebates to residents who employ Richmond contractors or RichmondBUILD graduates for installation of residential solar panels (i.e., photovoltaic (PV) systems) to generate electricity. Rebates are provided to both residents of single-family homes and owners of multi-family homes. Although the calculations described here are based on a single-family home, comparable greenhouse gas savings could be realized for multi-family housing (assuming adequate rooftop space is available).

1.5.1 Co-Benefits

Co-benefits of this measure include:

- Local job creation

³¹ Assumes 9.66 jobs are created per million dollars spent.

³² Assumes 95% of jobs created are full-time equivalent jobs.

³³ Does not assume that commercial beneficiaries will spend economic benefits within the community.

- Other energy efficiency programs complemented and promoted

Fewer natural resources used to produce energy at power plants

1.5.2 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-6 presents greenhouse gas emission reductions from residential solar rebates. The annual energy production of a typical 3-kW PV system is approximately to be 4,932 kWh.³⁴ The corresponding annual emission reduction of 0.9 MT was calculated using the greenhouse gas electricity emission factor for the City of Richmond.

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the residential solar rebate program. The annual emissions reductions for each year reflect cumulative reductions from retrofits completed in the current year and in all previous years.

The proposed residential Chevron mitigation rebate is \$2,000 per kW. Assuming a project lifetime of 25 years (CEC, 2013b), the carbon reduction effectiveness of the residential solar rebate program would be \$278 per MT.

1.5.3 Monitoring

The City of Richmond would monitor and verify the program by tracking the rebates issued and annual electricity generation (in kW-hr) for each home. The annual greenhouse gas emission reductions would be calculated using natural gas and electricity emission factors, such as the ones presented in Table A4.8-CGRP-19.

1.5.4 Leveraging

Residential solar costs are approximately \$6.00 per W (CSI, 2010).³⁵ For an average system size of 3 kW, the total cost of an average system would be \$18,000. Existing government rebates include the Federal Incentive Tax Credit (ITC) and the California Solar Initiative (CSI) rebate offered under the Expected Performance-Based Buydown (EPBB) program.^{36,37} Under the Federal ITC, eligible

³⁴ Go Solar Clean Power Estimator Calculator:
http://www.gosolarcalifornia.ca.gov/tools/clean_power_estimator.php. Accessed June 15, 2013. Used Richmond Zip code of 94801.

³⁵ Cost data from California Solar Initiative (CSI) General Market program data based on last 12 months for systems < 10kW (dated October 23, 2013).

³⁶ Federal Tax Code (Title 26 of United States Code [USC], Section 25D)

³⁷ California Solar Initiative Statewide Trigger Tracker. Available at: <http://www.csi-trigger.com/> (accessed October 28, 2013).

individuals may claim a one-time 30% tax credit on expenditures for solar PV systems. For a 3-kW system, that would be equivalent to \$5,400. Under the CSI, systems in the PG&E territory may be eligible for a rebate of \$0.20 per watt.³⁸ For a 3-kW system, that would be equivalent to \$600. The proposed residential Chevron mitigation rebate is \$2,000 per kW. For a 3-kW system, that would be equivalent to \$6,000. Thus, the resulting costs to the homeowner for a 3-kW system would be \$6,000 out of a total cost of \$18,000.

For lower income qualifying residents (80% Area Medium Income [AMI]), the proposed residential Chevron mitigation rebate will remain at \$2,000 per kW, but the remainder of the costs will be covered under the GRID Alternatives Single-Family Affordable Solar Homes Program (SASH).³⁹

Separate rebates are available to owners of multifamily low income housing buildings in California under the Multi-Family Affordable Solar Housing (MASH) Program. Under the program building owners can install solar PV systems to offset energy used in their building's common areas, and receive higher rebates for the energy they share with tenants.⁴⁰

1.5.5 Economic Benefit

In addition to energy savings, the Residential Solar Rebate program would represent an economic benefit to participants. Installation of a 3-kW PV system corresponds to annual energy savings of 4,932 kWh/home. Using the current PG&E electricity rate of \$0.14/kWh, this corresponds to an annual savings of \$697 per home.⁴¹

As a secondary benefit, the Residential Solar Rebate program would create jobs by (1) employing Richmond contractors and RichmondBUILD graduates to perform solar installation work; and 2) increasing spending within the community due to energy savings.

³⁸ The megawatt target has been reached but additional funding may be available. The PG&E Territory is currently under Step 10 with Expected Performance-Based Buydown (EPBB) Incentive Payments of \$0.20 per watt.

³⁹ SASH provides significant rebates on solar electric systems to qualifying single-family homeowners in PG&E service territories. The SASH program has been extended to 2021. Information on SASH can be found at: <http://www.gridalternatives.org/sash> (accessed October 15, 2013).

⁴⁰ Under MASH, owners of qualifying buildings can install solar PV systems to offset energy used in their building's common areas, and receive higher rebates for the energy they share with tenants. MASH applications in the PG&E service territory are currently being waitlisted due to limited budget. Information on MASH can be found at: <http://www.gosolarcalifornia.ca.gov/affordable/mash.php> (accessed February 12, 2014).

⁴¹ Average of Tier 1/2 PG&E electricity rates between May and August 2013.

1.5.5.1 Jobs Created from Residential Solar Installation Work

The assumed cost to install a residential PV system is \$6.00/watt (CSI, 2010).⁴² For a typical 3-kW system, this corresponds to job creation of 0.2 job-years (annual full-time equivalent) created per home (BEA, 2010a, 2010b).^{43,44}

1.5.5.2 Monetary Benefit to Community

Assuming customers would spend 90% of energy savings within the local community, the annual return to the community would be \$627 per home (BEA, 2013; US DOT, 2009).^{45,46} This corresponds to job creation of 0.007 jobs (annual full-time equivalent) created per home (BEA, 2010a, 2010b).^{47,48}

1.5.6 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.13:

- **Medium** – Create Local Jobs, Create Community Wealth & Resilience, Enhance Other Environmental Sustainability, Accurate Metric/Verifiable, Magnitude of Greenhouse Gas Reduction Available, Leveraging
- **Not applicable** – Reduce Local Greenhouse Gas Emissions, Improve Community Health

1.6 COMMERCIAL SOLAR REBATE

The Commercial Solar Rebate program reduces energy consumption in Richmond by providing solar rebates to businesses that employ Richmond contractors or RichmondBUILD graduates for installation of commercial photovoltaic systems.

1.6.1 Co-Benefits

Co-benefits of this measure include:

⁴² Cost data from California Solar Initiative (CSI) General Market program data based on last 12 months for systems < 10kW (dated October 23, 2013).

⁴³ Assumes 9.66 jobs are created per million dollars spent.

⁴⁴ Assumes 95% of jobs created are full-time equivalent jobs.

⁴⁵ The assumption that 10% of income is saved is meant to be a conservative assumption. In July 2013, the national saving rate was 4.4%.

⁴⁶ The assumption that all spending will be within the local community, is based on the 2009 overall average trip distance for the State of California of 8.79 miles, which means that all trips originating from Richmond would be within the boundary of Contra Costa County.

⁴⁷ Assumes 13.5 jobs are created per million dollars spent.

⁴⁸ Assumes 85% of jobs created are full-time equivalent jobs.

- local job creation
- other energy efficiency programs complemented and promoted
- fewer natural resources used to produce energy at power plants

1.6.2 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-7 presents greenhouse gas emission reductions from commercial solar rebates. The annual energy production of a 1-kW PV system was assumed to be 1,644 kWh.⁴⁹ The corresponding annual emission reduction of 0.3 MT/kW was calculated using the greenhouse gas electricity emission factor for the City of Richmond.

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the Commercial Solar Rebate program. The annual emissions reductions for each year reflect cumulative reductions from retrofits completed in the current year as well as in all previous years.

Assuming a project lifetime of 25 years (CEC, 2013b), the carbon reduction effectiveness of the Commercial Solar Rebate program would be \$67/MT.

1.6.3 Monitoring

The City of Richmond would monitor and verify the program by tracking the rebates issued and annual electricity generation (in kW-hr) for each building. The annual greenhouse gas emission reductions would be calculated using natural gas and electricity emission factors, such as the ones presented in Table A4.8-CGRP-19.

1.6.4 Leveraging

Commercial solar costs are approximately \$5,600 per kW (CSI, 2010).⁵⁰ Existing government rebates include the Federal ITC and the California Solar Initiative (CSI) rebate offered under the EPBB program.^{51,52} Under the Federal ITC, eligible businesses may claim a 30% tax credit on expenditures for solar PV systems. The equivalent tax credit would be \$1,670 per kW. Under the CSI, systems in the

⁴⁹ Go Solar Clean Power Estimator Calculator: http://www.gosolarcalifornia.ca.gov/tools/clean_power_estimator.php (Accessed June 15, 2013) Used Richmond Zip code of 94801.

⁵⁰ Cost data from California Solar Initiative (CSI) General Market program data based on last twelve months for systems > 10kW (dated October 23, 2013).

⁵¹ Federal Tax Code (Title 26 of United States Code [USC], Section 48)

⁵² California Solar Initiative Statewide Trigger Tracker. Available at: <http://www.csi-trigger.com/> (Accessed October 28, 2013)

PG&E territory may be eligible for a rebate of \$200 per watt.⁵³ The proposed residential Chevron mitigation rebate is \$500 per kW. Thus, the resulting costs to a qualifying business would be \$3,400 per kW out of a total cost of \$5,600 per kW.

1.6.5 Economic Benefit

In addition to energy savings, the commercial solar rebate program would create jobs by employing Richmond contractors and RichmondBUILD graduates.

The assumed cost to install a commercial PV system is \$5.6 per watt or \$5,600 per kW (CSI, 2010).⁵⁴ The corresponding jobs metric would be 0.05 job-years (annual full-time equivalent) created per kW installed (BEA, 201a, 2010b).^{55,56}

1.6.6 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.14

- **Medium** – Magnitude of Greenhouse Gas Reduction Available, Create Local Jobs, Create Community Wealth & Resilience, Enhance Other Environmental Sustainability, Accurate Metric/Verifiable, Leveraging
- **Not applicable** – Reduce Local Greenhouse Gas Emissions, Improve Community Health

1.7 PEDESTRIAN AND BICYCLE MASTER PLANS IMPLEMENTATION

Implementation of the City of Richmond Pedestrian Plan and Bicycle Master Plan would reduce vehicle-generated greenhouse gas emissions by encouraging walking and bicycling through providing improvements to bicycle and pedestrian paths in the city. The Bicycle Master Plan focuses on the development of a complete on-street bicycle network, building safe and accessible connections to the Bay Trail and Richmond Greenway, and reducing barriers, such as freeway interchanges and railroad crossings. The Pedestrian Plan focuses on capital

⁵³ The megawatt target for the PG&E service territory has been reached but additional funding may be available. The PG&E Territory is currently under Step 10 with Expected Performance-Based Buydown (EPBB) Incentive Payments of \$0.20 per watt.

⁵⁴ Cost data from California Solar Initiative (CSI) General Market program data based on last 12 months for systems > 10kW (dated October 23, 2013).

⁵⁵ Assumes 9.66 jobs are created per million dollars spent.

⁵⁶ Assumes 95% of jobs created are full-time equivalent jobs.

improvement projects and ongoing maintenance and upgrade projects for the citywide pedestrian system.

1.7.1 Co-Benefits

Co-benefits of this measure include:

- Improved local air quality
- Health benefits from exercise
- Encouraged economic activity along commercial arteries
- Reduced crime

1.7.2 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-8 presents annual greenhouse gas reductions from implementation of the Pedestrian Plan and Bicycle Master Plan. Based on the City of Richmond's 2005 greenhouse inventory, annual greenhouse gas emissions from transportation on local roads are 178,743 MT CO₂e from gasoline-fueled vehicles.⁵⁷ The program goal is to achieve a 2% reduction in local road emissions or 3,575 MT CO₂e per year (CAPCOA, 2010; City of Walnut Creek, 2012).^{58,59}

Table A4.8-CGRP-18 presents year-by-year emissions reductions from implementation of the Pedestrian Plan and Bicycle Master Plan. The year-by-year emissions reductions assume full implementation of the plan beginning with the first year.

The City of Walnut Creek estimates the cost to the city for the implementation of their Bicycle Master Plan is \$30,000,000 (City of Walnut Creek, 2012). The estimated greenhouse gas reduction potential is 5,835 MT CO₂e per year. Assuming a similar project lifetime of 25 years, the greenhouse gas reduction cost effectiveness is \$205 per MT CO₂e.

The City of Berkeley estimates that the cost of implementation of its bicycle master plan is \$7 million (City of Berkeley, 1998). The estimated reduction in greenhouse gas emissions is 1,157 MT CO₂e per year (City of Berkeley, 2009).

⁵⁷ Greenhouse gas emissions from transportation on local roads taken from the 2005 greenhouse gas inventory for the City of Richmond.

⁵⁸ The local road emissions reduction goal is consistent with the California Air Pollution Control Officers Association (CAPCOA) Quantifying Greenhouse Gas Mitigation Measures document, which estimates up to 2% reduction in greenhouse gas emissions from pedestrian network improvements. (Measures SDT-1)

⁵⁹ The City of Walnut Creek Climate Action Plan estimates a 2.3% reduction in local road greenhouse gas emissions from the implementation of the City's Master Bicycle Plan.

Assuming a similar project lifetime of 25 years, the greenhouse gas reduction cost effectiveness is \$242 per MT CO₂e.

1.7.3 Monitoring

The City of Richmond would monitor and verify the program by tracking path improvements and conducting surveys to determine how the community is utilizing the new paths. This information would allow an estimate of the reduction in vehicle miles traveled as a result of program implementation, which could in turn be used to calculate the reduction in greenhouse gas emissions.

1.7.4 Leveraging

There is no leveraging of costs for the Pedestrian Plan and Bicycle Master Plan.

There may be potential leveraging opportunities through the CalTrans Bicycle Transportation Account (BTA), an annual program that provides state funds for city and county projects that improve the safety and convenience for bicycle commuters.⁶⁰

1.7.5 Economic Benefit

In addition to energy savings, the Pedestrian Plan and Bicycle Master Plan would represent an economic benefit to the local community by encouraging economic activity along commercial arteries.

1.7.6 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.14:

- **High** – None
- **Medium** – Reduce Local Greenhouse Gas Emissions, Improve Community Health, Create Community Wealth & Resilience, Enhance Other Environmental Sustainability, Magnitude of Greenhouse Gas Reduction Available, Leveraging
- **Not applicable** – Create Local Jobs, Accurate Metric/Verifiable

⁶⁰ Caltrans Bicycle Transportation Account. Accessed October 30, 2013.
<http://www.dot.ca.gov/hq/LocalPrograms/bta/btawebPage.htm> .

1.8 ELECTRIC VEHICLES

1.8.1 Electric Vehicle Purchase Rebate

Implementation of the electric vehicle rebate program would reduce vehicle-generated greenhouse gas emissions by providing rebates to residents for the purchase of electric vehicles.

1.8.2 Co-Benefits

Co-benefits of this measure include:

- Fewer local criteria pollutant emissions
- Less energy usage overall
- Additional money spent in the community

1.8.3 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-9 presents annual greenhouse gas reductions from the electric vehicle purchase rebate program. Annual greenhouse gas savings were calculated as the difference in greenhouse gas emissions between a gasoline-fueled vehicle and an electric vehicle. Both vehicle types were assumed to be driven 13,746 miles per year, based on the national average (FHWA, 2011).⁶¹

1.8.3.1 Gasoline-Fueled Vehicle Greenhouse Gas Emissions

Greenhouse gas emissions from a gasoline-fueled vehicle were calculated assuming the vehicle has a fuel efficiency equivalent to the average fuel efficiency for light-duty vehicles (23.5 miles per gallon) (US DOT, 2010). The corresponding annual vehicle fuel consumption would be 573 gallons/year (FHWA, 2011). Greenhouse gas emissions were calculated using a greenhouse gas gasoline emission factor of 19.4 pounds CO₂e per gallon of gasoline consumed (EPA, 2005). Greenhouse gas emissions from a gasoline-fueled vehicle were thus estimated at 5.0 MT CO₂e per year.

1.8.3.2 Electric Vehicle Greenhouse Gas Emissions

Greenhouse gas emissions for an electric vehicle were calculated assuming the vehicle to have a fuel economy comparable to a 2013 Nissan Leaf (29 kW-hr/100 miles).^{62,63} The equivalent annual charge would be 3,908 kW-hr per year. The

⁶¹ Based on the average annual miles per driver.

⁶² The greenhouse gas emissions associated with operation of an electric vehicle are indirect emissions. These emissions are not emitted at the vehicle. Rather, they are emitted at the power plant where the electricity is generated to power the vehicle.

⁶³ 2013 Nissan Leaf Fuel Economy obtained from the EPA. Available at:

corresponding greenhouse gas emissions were calculated using the greenhouse gas electricity emission factor for the City of Richmond. Greenhouse gas emissions from an electric vehicle were thus estimated at 0.7 MT per year.⁶⁴

The net average vehicle greenhouse gas emissions reduction from replacing a gasoline-fueled vehicle with an electric vehicle would be 4.4 MT per year.

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the electric vehicle rebate program. The annual emissions reductions for each year reflect cumulative reductions from cars replaced in the current year as well as in previous years.

The proposed Chevron mitigation rebate for purchase of electric vehicles is \$1,000 per qualifying electric vehicle. Assuming a project lifetime of 15 years, the cost effectiveness of the electric vehicle purchase rebate would be \$15 per MT.

1.8.4 Monitoring

The City of Richmond would monitor and verify the program by tracking rebates issued. The annual greenhouse gas emission reductions would be calculated using either an average vehicle greenhouse gas emissions reduction, such as the one described above, or using more refined information obtained from rebate applicants regarding the types of vehicles being replaced and purchased.

1.8.5 Leveraging

The typical cost for a new Nissan Leaf S is \$28,800 (manufacturer's suggested retail price).⁶⁵ Federal tax credits are available up to \$7,500.⁶⁶ California Environmental Protection Agency's Air Resources Board also provides rebates of up to \$2,500.⁶⁷ The proposed Chevron mitigation rebate for purchase of electric

<http://www.fueleconomy.gov/feg/Find.do?action=sbs&id=33558>, accessed October 2013.

⁶⁴ Based on an average of 13,476 miles driven in a year.

⁶⁶ Information on the IRS Plug-In Electric Drive Vehicle Credit (IRC 30C) is available at: <http://www.irs.gov/Businesses/Plug-In-Electric-Vehicle-Credit-%28IRC-30-and-IRC-30D%29>, accessed October 20, 2013.

⁶⁷ Information on the Clean Vehicle Rebate Project (CVRP) is available at: http://energycenter.org/programs/clean_vehicle_rebate_project, accessed April 12, 2014.

vehicles is \$1,000 per qualifying electric vehicle. Thus, the resulting cost to owner would be roughly \$17,800.⁶⁸

1.8.6 Electric Vehicle Charging Station

Implementation of the electric vehicle charging station program would reduce vehicle-generated greenhouse gas emissions by providing rebates to residents and business for installation of electric vehicle charging stations.

1.8.7 Co-Benefits

- Co-benefits of this measure include:
- Modernization of the City's infrastructure
- Lower criteria air pollutant emissions
- Less energy usage overall
- Additional money spent in the community

1.8.8 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-10 presents annual greenhouse gas reductions from the electric vehicle charging station program. The greenhouse gas emissions saved on a per mile basis is calculated by taking the average greenhouse gas emissions savings per person per year (4.4 tonnes per year, Table A4.8-CGRP-9) and dividing by the average number of miles driven per person per year (13,476 miles per year, Table A4.8-CGRP-9). The number of annual vehicle miles traveled switched to electric vehicle per station is calculated assuming 2 chargers per station, a charger is used 8 hours per day, and the miles per charge of a Nissan Leaf.⁶⁹ The annual greenhouse gas emissions savings per station installed is 35 MT CO₂e per year.

The estimated cost per charging station is \$30,000.⁷⁰ Assuming a 10-year lifetime of the project, the cost effectiveness for the electric vehicle station program would be \$85 per MT.⁷¹

⁶⁸ The calculation of electric vehicle cost to owner is consistent with industry practice based on information available at: <http://www.driveclean.ca.gov/pev/Costs/Vehicles.php>

⁶⁹ The Nissan Leaf gets 75 miles after a 4-hour charge using a 6.6-kW charger, or 18.75 miles per hour charged. Available at: <http://www.fueleconomy.gov/feg/evsbs.shtml#midsize-cars>, accessed December 31, 2013.

⁷⁰ Equipment cost, annual monitoring/maintenance, and installation cost provided by ChargePoint for Model CT4021m Level II.

⁷¹ Lifetime based on assumption used in Financial Viability of Non-Residential Electric Vehicle Charging Stations (UCLA, 2012).

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the electric vehicle charging station program. The annual emissions reductions for each year reflect cumulative reductions from stations installed in the current year as well as in all previous years.

1.8.9 Monitoring

The City of Richmond would monitor and verify the program by tracking rebates issued and conducting user surveys. This information would allow an estimate of the number of gasoline trips replaced by electric trips as a result of program implementation, which could in turn be used to calculate the reduction in greenhouse gas emissions.

1.8.10 Leveraging

There is no leveraging of costs for the electric vehicle charging station program.

1.8.11 Economic Benefit

In addition to energy savings, the electric vehicle purchase rebate and electric vehicle charging station programs would represent an economic benefit to participants due to replacement of gasoline-fueled vehicle trips with lower-cost electric vehicle trips.

1.8.12 Prioritization

Based on the above, these measures received the following ratings when evaluated against the prioritization criteria described in Section 1.14

- **High** –Magnitude of Greenhouse Gas Reduction Available
- **Medium** – Reduce Local Greenhouse Gas Emissions, Improve Community Health, Create Community Wealth & Resilience, Enhance Other Environmental Sustainability, Accurate Metric/Verifiable, Leveraging
- **Not applicable** – Create Local Jobs

1.9 RIDE SHARE/GREEN TRANSPORTATION

The ride share program would encourage the availability of low-greenhouse-gas transportation alternatives such as the use of a local shuttle circular or a van service. Greenhouse gas savings can be realized as individual trips in personal vehicles are eliminated as residents use the shuttles.

1.9.1 Co-Benefits

Co-benefits of this measure include:

- Fewer overall criteria pollutant emissions
- Less traffic congestion
- Personal savings

1.9.2 Greenhouse Gas Reductions and Costs

1.9.3 Local Shuttle Circular

Table A4.8-CGRP-11 presents annual greenhouse gas reductions from the current Richmond Circular Bus program as an illustration of the emission savings that can be realized. The Richmond Circular Bus is a free bus service that provides stops at Richmond BART, Civic Center, Marina Bay, and other locations. Annual greenhouse gas savings were calculated as the difference between the emissions from operation of the shuttle bus and the use of personal vehicles.

1.9.3.1 Shuttle Emissions

Greenhouse gas emissions from the shuttle were calculated using the annual reported vehicle miles traveled (VMT) for the existing shuttles (38,760 miles for a total of 101,520 boardings) and the emission factor for similar vehicles in California (1.53 lb CO₂e/mile).^{72,73} The resulting greenhouse gas emissions from the shuttle system were estimated at 27 MT CO₂e per year.

1.9.3.2 Personal Vehicle Emissions

Avoided greenhouse gas emissions from replaced personal vehicle trips were calculated by using the number of daily ridership of the shuttle (423 rides per day) and the weighted average origin-to-destination trip length (1.6 miles) reported by riders in a survey.⁷⁴ At operations of 240 days per year, the annual avoided VMT is 160,529 miles. Using an average emission factor for gasoline

⁷² VMT data for Richmond Circular Bus from Final Report, Shuttle Projects, BAAQMD Project #11R12 (9/13/13).

⁷³ The greenhouse gas emission factor was obtained from California Air Resources Board (CARB) EMFAC for OBUS category, model year 2015, aggregated speeds, taking into account Pavley and Low Carbon Fuel Standard (LCFS). Available at: <http://www.arb.ca.gov/emfac/>, accessed 10/20/2013.

⁷⁴ Ridership and trip length survey results for Richmond Circular Bus from Final Report, Shuttle Projects, BAAQMD Project #11R12 (9/13/13).

personal vehicles (0.83 lb CO₂e/mile), the avoided greenhouse gas emissions are 60 MT CO₂e per year.⁷⁵

The net average vehicle greenhouse gas emissions reduction is 33 MT CO₂e per year under the current shuttle service provided in Richmond.

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the Richmond Circular Bus program. The year-by-year emissions reductions assume full implementation of the program during the first year.

An estimate for the cost effectiveness of this program can be made by considering that the annual cost of operations for the current shuttle service is \$369,000 per year.⁷⁶ Assuming Chevron will cover 25% of the program costs and the same level of service, the cost effectiveness of the program is roughly \$2,788 per MT CO₂e.

1.9.4 Van Service

The van service would organize passenger shuttle vans for shopping, event trips, and other local trips. There would be a \$2.00 per passenger fee for use of the shuttle. Table A4.8-CGRP-12 presents annual greenhouse gas reductions based on the existing van service program as an illustration of the emission savings that can be realized through that program. Annual greenhouse gas savings were calculated as the difference between the emissions between operation of the shuttle van and the use of personal vehicles.

1.9.4.1 Shuttle Emissions

Assuming an annual cost of \$13,560 as a basis, greenhouse gas emissions from the shuttle were calculated based on making 44 trips per month (with six people per trip) with each trip at 20 miles (Greenprint Transportation System, 2008). An emission factor typical of a passenger van is used in this calculation (2.2 lb CO₂e/mile).⁷⁷ Greenhouse gas emissions from the shuttle system were thus estimated at 11 MT CO₂e per year under the current system.

⁷⁵ Calculated based on emission factor for gallon of gasoline (19.4 lb CO₂e/gal) and average miles per gallon of US fleet (23.5 miles/gal) (US DOT, 2010; EPA, 2005).

⁷⁶ Provided by F. Kahn of TransMetro.

⁷⁷ The greenhouse gas emission factor was obtained from California Air Resources Board (CARB) EMFAC for LHD1 category, model year 2015, aggregated speeds, taking into account Pavley and Low Carbon Fuel Standard (LCFS). Available at: <http://www.arb.ca.gov/emfac/>, accessed 10/20/2013.

1.9.4.2 Personal Vehicle Emissions

Greenhouse gas emissions from replaced personal vehicle trips were calculated by using the number of annual ridership of the shuttle (44 trips per month with six people per trip) and the trip length (20 miles) (Greenprint Transportation System, 2008). The annual avoided VMT is 63,360 miles. Using an average emission factor for gasoline personal vehicles (0.83 lb CO₂e/mile), the avoided greenhouse gas emissions are 24 MT CO₂e per year under the current program.⁷⁸

The resulting net average vehicle greenhouse gas emissions reduction is 13 MT CO₂e per year under the van service under the current program.

An estimate for the cost effectiveness of this program can be made by considering that the annual cost basis for the van service is \$13,560. With the \$2.00 passenger fee, the net annual cost for operation of the van service under the current program is \$4,716 per year. Thus, the cost effectiveness of the program is approximately \$358 per MT CO₂e.

1.9.5 Monitoring

The City of Richmond would monitor and verify the program by tracking the number of shuttle and van trips per year and conducting user surveys. This information would allow an estimate of the reduction in vehicle miles traveled as a result of program implementation, which could in turn be used to calculate the reduction in greenhouse gas emissions.

1.9.6 Leveraging

1.9.6.1 Local Shuttle Circular

The proposed Chevron contribution for the local shuttle circular would be 25% of the total cost.

1.9.6.2 Van Service

The proposed Chevron contribution for the van service would be approximately 35% of the total cost as the rest would be provided by revenues from passenger fares.

⁷⁸ Calculated based on emission factor for gallon of gasoline (19.4 lb CO₂e/gal) and average miles per gallon of US fleet (23.5 miles/gal) (US DOT, 2010; EPA, 2005).

1.9.7 Economic Benefit

In addition to energy savings, the ride share program would represent an economic benefit to participants due to replacement of personal vehicle trips with free or low-cost shuttle trips.

1.9.8 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.13:

- **High** – None
- **Medium** – Create Local Jobs, Reduce Local Greenhouse Gas Emissions, Improve Community Health, Create Community Wealth & Resilience, Enhance Other Environmental Sustainability, Magnitude of Greenhouse Gas Reduction Available
- **Not applicable** –Accurate Metric/Verifiable, Leveraging

1.10 BICYCLE PROGRAM

The bicycle program would reduce energy consumption by developing a public bike sharing system. Residents and visitors would be able to rent bicycles by the hour. Bicycles could be picked up and dropped off at secure designated stations throughout the city. Greenhouse gas savings would be realized as individual trips typically taken in personal vehicles are eliminated as residents use non-emitting bicycles.

1.10.1 Co-Benefits

Co-benefits of this measure include:

- Less overall criteria pollutant emissions
- Less traffic congestion
- Personal savings
- Healthier habits through increased physical activity

1.10.2 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-13 presents annual greenhouse gas reductions from the bicycle program as an illustration of the emission savings that can be achieved. Annual greenhouse gas savings are calculated as the emissions that would have been emitted had a user driven a personal vehicle. The cost basis for this example is \$500,000 for a 10-year program. The number of daily vehicle trips that would be

replaced by bicycle trips is 200 trips per day with average trip lengths of 3 miles per trip.⁷⁹ Thus, the annual VMT that are replaced by bicycles is 219,000 miles per year. Given an average greenhouse gas emission factor for vehicles of 0.83 pounds of CO₂e per mile, the greenhouse gas emissions savings per the basis cost amount is 82 MT CO₂e per year.⁸⁰

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the bicycle program. The year-by-year emissions reductions assume full implementation of the plan beginning with the first year.

Assuming a cost basis of \$500,000 for an estimated lifetime of 10 years, the cost effectiveness of the program is \$611 per MT CO₂e. The cost effectiveness value is comparable to that for the Denver bike sharing program where annual net operating costs are \$241,480 for greenhouse gas emissions savings of 366 MT CO₂e per year, resulting in a cost effectiveness of \$660 MT CO₂e per year.⁸¹

1.10.3 Monitoring

The City of Richmond would monitor and verify the program by collecting ridership data and conducting user surveys. The survey results would allow an estimate of the reduction in vehicle miles traveled as a result of program implementation, which could in turn be used to calculate the reduction in greenhouse gas emissions.

1.10.4 Leveraging

There is no leveraging of costs for the bicycle program.

1.10.5 Economic Benefit

In addition to energy savings, the bicycle program would represent an economic benefit to participants due to replacement of personal vehicle trips with no-cost bicycle trips.

⁷⁹ Daily trip replacement, trip length, and program cost provided by F. Kahn of TransMetro.

⁸⁰ Greenhouse gas emission factor on a per mile basis calculated based on emission factor for gallon of gasoline (19.4 lb CO₂e/gal) and average miles per gallon of US fleet (23.5 miles/gal). (US DOT, 2010; EPA, 2005)

⁸¹ Operating costs and greenhouse gas savings obtained from Denver Bike Sharing (DBS, 2012). Note that the net operating cost includes sponsorships, membership fees, and usage fees. Removal of this income would increase the cost effectiveness value.

1.10.6 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.13:

- **High** – None
- **Medium** – Reduce Local Greenhouse Gas Emissions, Improve Community Health, Create Community Wealth & Resilience, Enhance Other Environmental Sustainability, Magnitude of Greenhouse Gas Reduction Available
- **Not applicable** – Create Local Jobs, Accurate Metric/Verifiable, Leveraging

1.11 TRANSIT ACCESS

The transit access program would provide reduced cost public transportation access through subsidized Clipper Cards that can be used on all transit agencies in the San Francisco Bay Area. Discounted Clipper Cards would encourage the use of public transportation over the use of private vehicles.

1.11.1 Co-Benefits

Co-benefits of this measure include:

- Less overall criteria pollutant emissions
- Less traffic congestion
- Personal savings
- Healthier habits through increased physical activity

1.11.2 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-14 presents annual greenhouse gas reductions from the transit access program as an illustration of the emission savings that can be achieved. A similar program in Contra Costa and Alameda Counties (TransLink for Transit-Oriented Development [T4T]) has shown annual greenhouse gas emission savings per program participant to be 0.19 MT CO₂e per year.⁸² Under the T4T program, the cost for each program participant was \$16 per month.⁸³ Assuming

⁸² Based on greenhouse gas reduction data from the TransLink for Transit Oriented Development (T4T) Pilot Program conducted in Contra Costa and Alameda Counties between 2008 and 2009. An estimated 475,842 pounds CO₂ was reduced for 1,367 participants. Of the 1,367 participants, 422 received 6-month passes and 945 received annual passes (Cambridge Systematics, Inc., 2010).

⁸³ Based on cost data from the T4T Pilot Program. Total program cost was \$225,000 dollars (includes transit pass costs and administrative costs) for 1,367 program participants. Of the 1,367 participants, 422 received 6-month passes and 945 received

Chevron subsidizes 50% of the program costs, Chevron's proposed contribution for each program participant would be \$8 per month. Thus, the corresponding cost effectiveness of the transit access program would be \$521 per MT. It is possible that the cost effectiveness for a program in Richmond would be lower (i.e., the higher dollars per metric ton saved) since the T4T study is based on transit-oriented development, which is likely to have higher rates of transit usage compared to non-transit-oriented development.

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the transit program. The year-by-year emissions reductions assume full implementation of the program beginning with the first year.

1.11.3 Monitoring

The City of Richmond would monitor and verify the program by obtaining electronic data of Clipper Card utilization, provided by the transit agencies, and conducting user surveys. This information would allow an estimate of the reduction in vehicle miles traveled as a result of program implementation, which could in turn be used to calculate the reduction in greenhouse gas emissions.

1.11.4 Leveraging

The proposed Chevron contribution for the transit access program would be 50% of the total program cost.

1.11.5 Economic Benefit

In addition to energy savings, the transit access program would represent an economic benefit to participants due to replacement of personal vehicle trips with reduced cost public transportation.

1.11.6 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.13:

- **High** – None
- **Medium** – Reduce Local Greenhouse Gas Emissions, Improve Community Health, Create Community Wealth & Resilience, Enhance Other Environmental Sustainability, Magnitude of Greenhouse Gas Reduction Available

annual passes. The cost used here absorbs the cost for pass holders who chose not to participate in the program.

- **Not applicable** – Create Local Jobs, Accurate Metric/Verifiable, Leveraging

1.12 WETLANDS CREATION

Creation of a vernal pool or other wetland type in the City of Richmond would sequester CO₂.

1.12.1 Co-Benefits

Co-benefits of this measure include:

- Creation of a habitat for plant and animal species
- Water quality buffering
- Stormwater runoff mitigation
- Water storage
- Flood conveyance
- Flood storage
- Wave attenuation
- Erosion control
- Production of natural resources
- Recreational and other human uses
- Improved aesthetics

1.12.2 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-15 presents annual greenhouse gas savings from the wetlands restoration program. The wetland was assumed to sequester CO₂ at a rate of 1.56 MT per acre per year during the first 5 years.⁸⁴ After the first 5 years, the wetland was assumed to sequester CO₂ at a lower rate of 0.34 MT per acre per year (Hansen, 2009).

Table A4.8-CGRP-15 presents wetlands restoration costs under two scenarios, a more conservative scenario (Scenario 1) and a less conservative scenario (Scenario 2).

1.12.2.1 Scenario 1 (Includes Cost of Land)

Conservative land, design, construction, and maintenance costs were included under Scenario 1. Land and construction costs were assumed to be \$300,000 per acre based on costs for registered wetlands for mitigation in urban areas of

⁸⁴ Based on carbon sequestration for a prairie pothole wetland (Euliss, 2006).

northern California.⁸⁵ Maintenance costs were assumed to be 5% of construction costs, or \$15,000 per acre (CASQA, 2003). Assuming a project lifetime of 25 years, total project costs would be approximately \$660,000 per acre. The total greenhouse gas sequestration over the 25-year lifetime would be 14.6 MT CO₂e per acre. Thus, the cost effectiveness would be roughly \$45,000/MT CO₂e.

1.12.2.2 Scenario 2 (Assumes Land Available For Free)

In Scenario 2, land for wetland construction was assumed to be available at no cost (or purchased with leveraged funds). Only design, construction and maintenance costs were assumed. Estimated construction costs were assumed to be \$29,000 per acre.⁸⁶ A fixed maintenance cost of \$3,000 per year was assumed. Assuming a project lifetime of 25 years, total project costs would be approximately \$101,000 per acre. The total greenhouse gas sequestration over the 25-year lifetime would be 14.6 MT CO₂e per acre. Thus, the cost effectiveness would be roughly \$7,000 per MT CO₂e.

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the wetlands creation program. The year-by-year emissions reductions assume full implementation of the program beginning with the first year.

1.12.3 Monitoring

The City of Richmond would monitor and verify the program through wetland surveys to determine square acreage. The annual greenhouse gas emission reduction could be calculated as the wetland square acreage multiplied by wetland CO₂ sequestration rates, such as the rates presented above.

1.12.4 Leveraging

There is no leveraging of costs for the wetlands creation program.

1.12.5 Economic Benefit

The wetlands creation program does not represent a direct economic benefit to the community, although property values could potentially increase due to improved aesthetics.

⁸⁵ Registered wetlands used for mitigation have been estimated to cost \$100,000 to \$300,000 per acre in urban areas of northern California (Reub, 2010). The highest value was assumed in cost-effectiveness calculations.

⁸⁶ Based on typical construction cost for a 10-acre wetland (Brown and Schueler, 1997).

1.12.6 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.14:

- **High** – Enhance Other Environmental Sustainability
- **Medium** – Reduce Local Greenhouse Gas Emissions, Accurate Metric/Verifiable, Leveraging, Magnitude of Greenhouse Gas Reduction Available
- **Not applicable** – Create Local Jobs, Improve Community Health, Create Community Wealth & Resilience

1.13 2-MW SOLAR PROJECT

The 2-megawatt (MW) solar project reduces energy consumption in Richmond through construction of a 2-MW ground-mounted photovoltaic solar facility on approximately 13 acres of Chevron property. The facility would supply the northern California electric grid.

1.13.1 Co-Benefits

Co-benefits of this measure include:

- Local job creation
- Fewer natural resources used to produce energy at power plants

1.13.2 Greenhouse Gas Reductions and Costs

Table A4.8-CGRP-16 presents annual greenhouse gas savings from the 2-MW solar project. The projected annual energy output of the facility is 3,800 megawatt-hours (MWh). The corresponding annual emission reduction of 666 MT was calculated using the greenhouse gas electricity emission factor for the City of Richmond.

The gross cost of the project is estimated at \$7.8 million, based on the cost of a conventional solar facility.⁸⁷ Assuming the solar power developer receives a 30%

⁸⁷ Based on a gross cost estimate of \$2.4 million for a 615-kW conventional silicon solar facility (SunPower, 2011). The gross cost includes installation, operating, maintenance, and hardware expenses.

federal tax credit, the actual cost would be approximately \$5.5 million.⁸⁸ Assuming a project lifetime of 25 years, the cost effectiveness would be roughly \$328/MT CO₂e.⁸⁹

Table A4.8-CGRP-18 presents year-by-year emissions reductions from the 2-MW solar project. The year-by-year emissions reductions assume full implementation of the project beginning with the first year.

1.13.3 Monitoring

The City of Richmond would monitor and verify the program by tracking the power supplied to the grid. The annual greenhouse gas emission reductions would be calculated using electricity emission factors, such as the ones presented in Table A4.8-CGRP-19.

1.13.4 Leveraging

The cost to install the 2-MW solar project is leveraged by a federal tax rebate. Although an incentive program is also operated at the state level, this program is currently closed in PG&E's service territory, as the allocated budget has already been spent.⁹⁰

1.13.5 Economic Benefit

There would be a local economic benefit from this measure if construction and maintenance jobs were sourced from the community.

1.13.6 Prioritization

Based on the above, this measure received the following ratings when evaluated against the prioritization criteria described in Section 1.14:

- **High** – Accurate Metric/Verifiable
- **Medium** – Create Local Jobs, Enhance Other Environmental Sustainability, Improve Community Health, Create Community Wealth & Resilience, Magnitude of Greenhouse Gas Reduction Available

⁸⁸Federal Solar Investment Tax Credit (ITC). Available at: <http://energy.gov/savings/business-energy-investment-tax-credit-itc>, accessed February 12, 2014.

⁸⁹ Lifetime based on assumption used in Valuing the Return on Solar Projects for Business and Government Agencies (SunPower, 2011)

⁹⁰ The California Solar Initiative (CSI) offers incentives to residential, commercial and government customers for solar system installation. Information on CSI can be found at: <http://www.cpuc.ca.gov/PUC/energy/Solar/>, accessed February 12, 2014.

1.14 PRIORITIZATION CRITERIA

Several criteria were considered in evaluating the measures included in the CGRP:

- **Cost effectiveness**⁹¹ – The cost effectiveness of measure in terms of cost per MT of greenhouse gas emission reductions. Certain measures are more cost effective (i.e., require less money to achieve a certain amount of greenhouse gas reductions) while other measures can be less cost effective (i.e., require more money to achieve a certain amount of greenhouse gas reductions.)
- **Local job creation** – The potential for a measure to create or maintain quality local jobs. Jobs are created from construction activities (e.g., energy efficiency retrofit work, installation of solar systems), increased recycling and composting activities, and tree planting and park maintenance activities. In addition, when residents save on energy costs this could translate into additional money to be spent in the community and the creation of additional local jobs.
- **Local greenhouse gas emission reductions** – The magnitude of greenhouse gas emission reductions to be achieved locally through implementation of the measure. Local greenhouse gas emission reductions tend to bring co-benefits to the community compared to greenhouse gas emission reductions that occur remotely.
- **Community health co-benefits** – The potential for a measure to improve community health by improving outdoor and indoor air quality (e.g., from reduced criteria air or toxic air pollutant emissions) and by promoting increased physical activity (e.g., walking or biking).

⁹¹ Cost effectiveness is one metric that can be used to compare different emission reduction programs. In a general sense, it represents how “effective” each dollar spent on a program is on reducing emissions. Highly cost-effective programs have relatively low cost effectiveness values. It takes fewer dollars to result in the same emission reductions compared to low cost-effective programs. Thus, cost effectiveness can help decision makers understand where dollars may be most effective at reducing emissions.

In general, cost effectiveness is calculated by dividing an annualized cost for a program by the annual emission reductions:

$$\text{Cost Effectiveness} \left(\frac{\$}{\text{MT CO}_2\text{e}} \right) = \frac{\text{Annualized Cost} \left(\frac{\$}{\text{yr}} \right)}{\text{Greenhouse Gas Emissions Reduction} \left(\frac{\text{MT CO}_2\text{e}}{\text{yr}} \right)} = \left(\frac{\$}{\text{MT CO}_2\text{e}} \right)$$

The annualized cost includes ongoing operational costs and one-time capital costs. One-time capital costs are annualized by the expected lifetime of the program. For purposes of this document, the capital costs are simply divided by the expected lifetime (in years) of the program. More refined methods exist, such as using a capital recovery factor (CRF) incorporating an assumed interest rate, but are not considered for purposes of this document.

- **Community wealth and resilience** – The potential for a measure to create community wealth and resilience (e.g., by reducing energy costs for residents, or enhancing the value of homes or other structures).
- **Other environmental sustainability enhancements** – The potential for a measure to enhance other types of environmental sustainability (e.g., waste diversion to recycling and compost bins, reduced fuel consumption, reduced energy consumption) or provide other environmental co-benefits (e.g., urban greening, habitat creation, improved groundwater quality).
- **Accurate metric/verifiable** – The availability of accurate metrics to measure and verify greenhouse gas reductions achieved through implementation of the measure.
- **Magnitude of greenhouse gas reductions available** – The magnitude of local greenhouse gas emissions available to be reduced through implementation of the measure. (Discussed in next section.)
- **Leveraging potential** – The potential for leveraging of additional resources for further greenhouse gas emission reductions through program enhancements or expansions.

The greenhouse gas reduction measures were evaluated against the prioritization criteria described above using a prioritization matrix (included as Table A4.8-CGRP-17). Each measure was evaluated against each criterion and assigned one of the following ratings:

- check (✓) = yes – applicable;
- plus (+) = yes – applicable and rates very highly; or
- dash (-) = no – not applicable.

1.15 HYPOTHETICAL CASE FOR BUDGET SPREAD

The following is a discussion of the methodology and assumptions used to calculate year-by-year emission reductions over a 10-year period from the CGRP, as presented in Table A4.8-CGRP-18.

As a hypothetical case, a total budget of \$30,000,000 was assumed to be evenly allocated over all programs.

For programs assumed to be fully implemented in the first year, year-by-year reductions were calculated by dividing the budget allocated to the measure by the cost effectiveness of the measure and assuming the allocated budget was spread over the lifetime of the project, or over the 10-year period for measures where a project lifetime was not specified.

For programs assumed to be implemented over the lifetime of the program, emissions reductions would increase each year. Thus, the year-by-year reductions take into account the percent of project completion for each year by multiplying by the ratio of the project age to the project lifetime. The allocated budget was assumed to be spread over the 10-year period for these programs in the hypothetical case.

1.16 MAXIMUM POTENTIAL GREENHOUSE GAS SAVINGS

The following is a discussion of the methodology and assumptions used to calculate maximum potential greenhouse gas savings from the CGRP, as presented in Table A4.8-CGRP-18. The maximum savings presented here are theoretical maxima based on the assumptions described below. These savings are not necessarily additive across programs, as there may be overlap in the estimated emission reductions (e.g., residential energy efficiency and residential energy efficiency for households below 80% AMI; electric vehicle rebate and electric vehicle charging stations).

1.16.1 Urban Forestry

Maximum potential greenhouse gas savings from the urban forestry program were calculated based on the assumption that enough trees could potentially be planted in Richmond to achieve the tree density of a well-performing city in terms of urban forestry. Sacramento and San Francisco are both well-performing cities with public tree densities of approximately 1.9 and 3.5 trees/acre, respectively.^{92,93} Assuming the tree density of San Francisco was achieved in Richmond, the number of trees planted would be approximately 125,149. Using the emission calculation methodology described in Section 1.1, the maximum annual greenhouse gas savings would be 10,218 MT CO₂e per year.⁹⁴

1.16.2 Zero Waste Programs

Maximum potential greenhouse gas savings from zero waste programs were calculated assuming a landfill diversion rate comparable to San Francisco. San Francisco is a well-performing city in terms of waste diversion with a diversion rate of approximately 80% (City and County of San Francisco, 2012). Assuming the same diversion rate were achieved in Richmond, the maximum annual

⁹² Based on 115,000 public trees in Sacramento and a total land area in Sacramento of 362,180 acres (American Forests, 2014).

⁹³ Based on 105,000 public trees in San Francisco and a total land area in San Francisco of 30,016 acres (SFPD, 2014; US CB, 2014).

⁹⁴ Based on a total land area in Richmond of 55.9 square miles (City of Richmond, 2012a).

greenhouse gas savings would be 27,794 MT CO₂e per year, using the emissions calculation methodology described in Section 1.2.

1.16.3 Residential Energy Efficiency

Maximum potential greenhouse gas savings from the residential energy efficiency rebate program were calculated assuming energy efficiency upgrades could be completed at all occupied homes in Richmond. Based on U.S. Census data, there are 35,884 occupied housing units in Richmond.⁹⁵ Assuming energy efficiency upgrades were completed at all housing units, the maximum annual greenhouse gas savings would be 67,551 MT CO₂e per year, using the emissions calculation methodology described in Section 1.3.

Maximum potential greenhouse gas savings from the residential energy efficiency rebate program for lower-income qualifying residents were calculated assuming energy efficiency upgrades could be completed at all households in Richmond below 80% AMI. Based on the Richmond General Plan 2030, there are 13,267 households in Richmond below 80% AMI (City of Richmond, 2012a). Assuming energy efficiency upgrades were completed for all qualifying households, the maximum annual greenhouse gas savings would be 24,975 MT CO₂e per year, using the emissions calculation methodology described in Section 1.3.

1.16.4 Residential Solar Rebate

Maximum potential greenhouse gas savings from the residential solar rebate program were calculated assuming solar installation could be completed at all occupied homes in Richmond. Based on U.S. Census data, there are 35,884 occupied housing units in Richmond (City and County of San Francisco, 2012). Assuming solar installation were completed at all occupied housing units, the maximum annual greenhouse gas savings would be 31,032 MT CO₂e per year, using the emissions calculation methodology described in Section 1.5.

1.16.5 Commercial Energy Efficiency Rebate

Maximum potential greenhouse gas savings from the commercial energy efficiency rebate program were calculated assuming that energy consumption by Richmond businesses (excluding the Facility and other large industrial entities)

⁹⁵ Used U.S. Census Bureau housing unit estimates for Richmond based on data collected from 2007 through 2011 (US CB, 2011).

could be reduced by 50%.⁹⁶ Based on the Richmond General Plan 2030, annual greenhouse gas emissions from Richmond businesses (excluding the Facility and other large industrial entities) are approximately 1.18 million MT CO₂e per year.⁹⁷ Reducing these emissions by 50% would correspond to a maximum savings of 590,258 MT CO₂e per year.

1.16.6 Commercial Solar Rebate

Maximum potential greenhouse gas savings from the commercial solar rebate program were calculated based on the total square footage of commercial building space in Richmond. Based on the Richmond General Plan 2030, Richmond has 2.6 million square feet of commercial space (City of Richmond, 2012b). Richmond's total commercial square footage was converted to an estimated total "footprint" of 962,963 square feet using U.S. Energy Information Administration (EIA) data for commercial buildings in the United States (EIA, 2003).⁹⁸ Assuming 100% of commercial buildings are flat roof buildings (i.e., roof space is equal to the building footprint), 65% of commercial roof space is available for solar installation, and a photovoltaic density of 110 W per square meter, the corresponding maximum annual greenhouse gas savings would be 1,844 MT CO₂e per year, using the emissions calculation methodology described in Section 1.6.⁹⁹

1.16.7 Pedestrian and Bicycle Master Plans Implementation

Maximum potential greenhouse gas savings from implementation of the Pedestrian Plan and Bicycle Master Plan were calculated based on the proportion of miles traveled by bicycle or on foot (or modal split) by residents of Boulder, Colorado. Boulder, Colorado is a well-performing city with a modal split of 12.7% for bicycle and pedestrian miles (NRCI, 2012). Based on the City of Richmond's 2005 greenhouse gas inventory, annual greenhouse gas emissions from transportation on local roads are 178,743 MT CO₂e from gasoline-fueled

⁹⁶ The maximum reduction of 50% is based on the California Public Utilities Commission (CPUC) goal to convert 50% of existing commercial buildings to zero net energy buildings by 2030 (CPUC, 2011).

⁹⁷ Greenhouse gas emissions from the commercial sector taken from the 2005 greenhouse gas inventory for the City of Richmond.

⁹⁸ The total floor space of commercial buildings was scaled to estimate the total "footprint" based on EIA data for commercial buildings (e.g., percent of buildings that are one-story, two-story, etc.). An average number of floors per commercial building was calculated based on the following distribution (percent of total square feet shown in parentheses): one floor (40%), two floors (25%), three floors (12%), four to nine floors (16%), ten or more floors (8%). The minimum number of floors was assumed for the "four to nine" and "ten or more" categories.

⁹⁹ Used the estimated percentage of available roof space for commercial buildings in colder climates and photovoltaic density for flat roofs (NREL, 2008).

vehicles.¹⁰⁰ Assuming 12.7% of miles traveled on local roads were shifted to bicycle or travel on foot, the maximum greenhouse gas savings would be 22,700 MT CO₂e per year.

1.16.8 Electric Vehicle Rebate

Maximum potential greenhouse gas savings from the electric vehicle rebate program were calculated assuming rebates could be provided for all vehicles operated by Richmond residents. Assuming there are 18,710 households in Richmond that will buy one new car in the next 10 years, the corresponding maximum greenhouse gas savings would be 81,594 MT CO₂e per year, using the emission calculation methodology described in Section 1.8.¹⁰¹

1.16.9 Electric Vehicle Charging Stations

Maximum potential greenhouse gas savings from the electric vehicle charging station program were calculated assuming enough commercial charging stations were installed to reach a charging station density comparable to San Francisco. An estimated 182 commercial charging stations are present in San Francisco, corresponding to a charging station density of 0.006 charging stations per acre.¹⁰² If the same charging station density were achieved in Richmond, this would correspond to installation of approximately 217 charging stations.¹⁰³ Using the emission calculation methodology described in Section 1.8, the corresponding maximum greenhouse gas savings would be 7,687 MT CO₂e per year.

1.16.10 RideShare (Shuttle Circular Bus)

Maximum potential greenhouse gas savings from the use of a local shuttle circular service were calculated assuming that primary impact of shuttle operation would be to reduce the number of residents who drive alone to Richmond and El Cerrito Del Norte Bay Area Rapid Transit (BART) stations during the week. Assuming that all weekday single-occupied vehicle trips to these BART stations were switched to RideShare and that the shuttle operates 240 days per

¹⁰⁰ Greenhouse gas emissions from transportation on local roads taken from the 2005 greenhouse gas inventory for the City of Richmond.

¹⁰¹ Based on the number of households in Richmond with an annual household income of at least \$50,000 (City of Richmond, 2012a).

¹⁰² Number of charging stations in San Francisco obtained from ChargePoint, <http://www.chargepoint.com>, accessed December 19, 2013.

Total land area in San Francisco (30,016 acres) obtained from the United States Census Bureau (US CB, 2014).

¹⁰³ Based a total land area in Richmond of 55.9 square miles (City of Richmond, 2012a).

year, the annual avoided VMT would be approximately 2,849,955 miles.¹⁰⁴ Annual shuttle miles were calculated using the ratio of shuttle miles to VMT switched to RideShare from the Richmond Circular Bus program (ratio of 0.24 shuttle miles per mile switched to RideShare). Using this ratio, the annual shuttle VMT would be 688,129 miles per year. Using the emission calculation methodology described in Section 1.9, the annual greenhouse gas emissions removed from personal vehicles would be 1,066 MT CO₂e per year, the annual greenhouse gas emissions from shuttle operation would be 478 MT CO₂e per year, and the net maximum annual greenhouse gas savings would be 587 MT CO₂e per year.

1.16.11 RideShare (Van Service)

Maximum potential greenhouse gas savings from the use of a van service were calculated assuming that all residential non-work commuting trips could potentially be switched to RideShare. The annual avoided VMT was calculated using CalEEMod default trip generation rates for residential land use and default trip lengths for Contra Costa County. The default average trip rate for a single-family home was conservatively used (9.5 trips per day per dwelling unit).¹⁰⁵ The percentage of trips that are home-shopping trips and home-other trips was assumed to be 29.1% and 44.8%, respectively. The average trip length of home-shopping trips and home-other trips was assumed to be 4.3 and 5.4 miles, respectively.¹⁰⁶ Assuming 35,884 households in Richmond, the corresponding annual avoided VMT would be approximately 460 million miles.¹⁰⁷ Annual shuttle miles were calculated using the ratio of shuttle miles to VMT switched to RideShare from the Greenprint Transportation System (ratio of 0.17 shuttle miles per mile switched to RideShare). Using this ratio, the annual shuttle VMT would be 76 million miles per year. Using the emission calculation methodology described in Section 1.9, the annual greenhouse gas emissions removed from personal vehicles would be 171,308 MT CO₂e per year, the annual greenhouse gas emissions from shuttle operation would be 76,171 MT CO₂e per year, and the net maximum annual greenhouse gas savings would be 95,137 MT CO₂e per year.

¹⁰⁴ The annual avoided VMT is based on the following ridership data for Richmond residents on an average weekday: (1) 940 residents drive alone to the Richmond BART with a median car distance of 2.06 miles, and (2) 891 residents drive alone to the El Cerrito Del Norte BART station with a median car distance of 4.49 miles (BART, 2008).

¹⁰⁵ Based on the following CalEEMod default trip rates for single family homes (trips per day per dwelling unit): 9.57 (weekday), 10.08 (Saturday), 8.77 (Sunday).

¹⁰⁶ CalEEMod default trip type percentages and trip lengths for Contra Costa County.

¹⁰⁷ Used U.S. Census Bureau housing unit estimates for Richmond based on data collected from 2007 through 2011 (US CB, 2011).

1.16.12 Bicycle Share

Maximum potential greenhouse gas savings from the bicycle share program were calculated based on ridership data from bicycle share programs operated in well-performing U.S. cities. The maximum rides per day were calculated based on the population of Richmond and assuming an average ridership of 0.3 rides per day per person.^{108,109} Assuming that 43% of miles traveled by bicycle would replace vehicle trips and using the same emission calculation methodology described in Section 1.10, the maximum avoided VMT would be 13,950,747 miles and the corresponding maximum annual greenhouse gas savings would be 5,224 MT CO₂e per year.¹¹⁰

1.16.13 Transit Access

Maximum potential greenhouse gas savings from the transit access program were calculated assuming that all Richmond residents dwelling in multi-family residences with 20 or more units could be provided with transit passes. Based on the Richmond General Plan 2030, 3,482 housing units in Richmond are located within structures with 20 or more units (City of Richmond, 2012a). Assuming an average household size of 2.83 people per household, this corresponds to approximately 9,854 residents dwelling in these types of residences.¹¹¹ Assuming transit passes were distributed to all of these residents, the maximum annual greenhouse gas savings would be 1,840 MT CO₂e per year, using the same emission calculation methodology described in Section 1.11.

1.16.14 Wetlands Creation

Maximum potential greenhouse gas savings from the wetlands creation program were calculated assuming a wetland acreage equal to the largest wetland restoration program in Richmond (279.7 acres, Wildcat Creek Marsh Restoration Project).¹¹² Using the same emission calculation methodology described in

¹⁰⁸ Used Richmond population of 103,701. (City of Richmond, 2012a).

¹⁰⁹ Daily ridership based on survey results from the 2008 Capital Bikeshare Pilot Program (Washington, D.C.) (NLC, 2010).

¹¹⁰ Percent of miles that replace vehicle miles based on survey results from the 2008 B-Cycle Program (Denver, CO) (NLC, 2010).

¹¹¹ Average household size taken from the City of Richmond's General Plan 2030 (City of Richmond, 2012a).

¹¹² Based on information obtained from California EcoAtlas – San Francisco Estuary Institute. Available at: <http://www.ecoatlas.org/regions/ecoregion/bay-delta/projects>, accessed February 24, 2014.

Section 1.12, the maximum annual greenhouse gas savings would be 163 MT CO₂e per year.¹¹³

1.16.15 2-MW Solar Project

The maximum potential greenhouse gas savings from the 2-MW solar project are 666 MT CO₂e per year as described in Section 1.13.

1.17 CITY POLICY SYNERGIES

The City of Richmond has adopted several policies that aim to reduce the City's greenhouse gas footprint and meet the State's greenhouse gas reduction goals. These policies have informed the CGRP measures discussed above.

Examples of City policies and directives that address greenhouse gas emissions from industry in Richmond include the following:

- On September 16, 2008, the City Council passed Resolution No. 108-08, committing to the greenhouse gas emission reduction target established by Assembly Bill 32, which is 1990 levels by calendar year (CY) 2020, and also committing to targets established by Executive Order S-3-05, which include 2000 levels by CY 2010 and 80% below 1990 levels by CY 2050.
- Richmond General Plan 2030, adopted on April 25, 2012, includes an Energy and Climate Change Element that identifies policies and implementing actions to address energy and climate change needs, and outlines measures that can be implemented to reduce greenhouse gas emissions. Finding 5 of the Energy and Climate Element states that "Industries and businesses in Richmond should be encouraged to adopt green and sustainable practices and build capacity in the emerging green economy."
- General Plan Policy Energy and Climate Change Element EC5.2 calls on the City to "encourage existing businesses and industries to become increasingly environmentally progressive and continue making positive contributions to the community. Encourage businesses and industries to hire locally and to demonstrate reasons for not hiring local employees. Seek reciprocity in the hiring of Richmond residents in Contra Costa County and other nearby jurisdictions with local hiring ordinances. Encourage businesses and industries to participate in civic life and play a positive role in the community. Together with regulatory agencies, actively work with local

¹¹³ Since the method described in Section 1.12 assumes different CO₂ sequestration rates during the first 5 years of the wetland, the maximum annual greenhouse gas savings presented here represent the average annual savings over a 25-year project lifetime.

industries to ensure compliance with all applicable environmental regulations to limit pollution, decrease harmful impacts from emissions and protect the community from environmental hazards. Promote and encourage new clean and green industries that provide well-paying jobs, revenue and other community and environmental benefits; support efforts to require existing industries to decrease harmful emissions and impacts; and promote a mix of uses and a range of activities on industrial land to create jobs and revenue while avoiding conflict between industrial and nonindustrial uses."

- General Plan Land Use Element Policy LU3.7 encourages the City to "retain and support the modernization of Richmond's existing heavy industrial uses and support their continued transition to cleaner and more energy-efficient operations in order to reduce impacts to human and environmental health."

Examples of City policies and directives that support greenhouse gas reductions within Richmond include:

- General Plan Community Health and Wellness Element Policy HW10.4 encourages the City to "promote the generation, transmission and use of a range of renewable energy sources such as solar, wind power and waste energy to meet current and future demand and encourage new development and redevelopment projects to generate a portion of their energy needs through renewable sources."
- General Plan Community Health and Wellness Action HW9.G applies the Bay Area Air Quality Management District's CEQA thresholds of significance and mitigation measures to ensure that new facilities do not create additional net cumulative air pollution health impacts on sensitive uses. Mitigation could include measures to reduce air emissions, monitor exposure and prevent exposure.
- General Plan Housing Element Policy H-2.2 encourages the City to "promote the incorporation of green building measures and practices in new residential development projects and existing residential structures."
- General Plan Energy and Climate Change Element Policy EC3.2 encourages the City to "promote efficient use of energy and conservation of available resources in the design, construction, maintenance and operation of public and private facilities, infrastructure and equipment. Collaborate with partner agencies, utilities and businesses to support a range of energy efficiency, conservation and waste reduction measures including: development and retrofitting of green buildings and infrastructure; installation of energy-efficient appliances and equipment in homes and offices; and heightened awareness of energy and conservation issues. Collaborate with local

workforce development programs to train and employ Richmond residents in these other green jobs sectors."

- General Plan Energy and Climate Change Element Action EC6.E Urban Forestry Management Plan directs the City to "continue to implement the urban forest management plan to guide landscaping practices in urban areas of the City, reduce the heat-island effect and contribute to carbon mitigation."
- Bicycle Master Plan, adopted by the Richmond City Council on November 1, 2011, sets forth a blueprint for completion of a 145-mile system of bikeways and support facilities within Richmond. The plan builds upon the existing system of on-street and off-street bicycle facilities throughout the city, focusing on connections between neighborhoods, safe routes to schools and access to major destinations such as employment centers, stores and shops, parks, trails and open space areas.
- Pedestrian Plan, adopted by the Richmond City Council on November 1, 2011 aims to improve the safety, convenience and appeal of walking throughout the city by making specific recommendations on how to overcome obstacles to safe walking.

Table A4.8-CGRP-1
Urban Forestry
Community GHG Reduction Program
Richmond, California

GHG Emissions Reduction Factor Basis

	Value	Units	Notes/Source
Number of Trees (Basis)	50	million trees	Accounts for carbon sequestration and energy savings effects from shading.
GHG Emissions Reduction	4.5	million short tons CO2 annually	US Forest Service, Center for Urban Forest Research. Available at: http://www.fs.fed.us/ccrc/topics/urban-forests/ . Accessed: October 2, 2013.
GHG Emissions Reduction Factor	0.082	MT CO2 per year per tree	

Costing Basis

		Tree Type		
		Right of Way Trees	Park Trees	Trees to Residents
	\$ per tree \ Quantity	2,000	1,000	2,000
Cost of Tree	\$40	\$80,000	\$40,000	\$80,000
Cost of Tree Equipment (stakes, ties, fertilizer)	\$12	\$24,000	\$12,000	\$24,000
Costs of Planting in City Right of Way	\$100	\$200,000		
Costs of Maintaining in City Right of Way	\$40	\$80,000		
Costs of Planting in City Parks	\$50		\$50,000	
	Total	\$590,000		

Total Cost Per Tree	\$118	Average cost per tree	Costing information from the City of Richmond Parks Department. The average cost per tree is calculated by the total costs above divided by the number of trees in the basis.
----------------------------	--------------	------------------------------	---

Cost Effectiveness

	Value	Units	Source/Notes
GHG Emissions Reduction Factor	0.082	MT CO2 per year per tree	From above
Lifetime of Project	25	years	The California Air Resources Board (ARB) uses a 25-year crediting period for urban forest offset projects. Source: ARB. 2011. GHG Reduction													21,838

Notes:

1. Waste disposal was derived from the West Contra Costa Integrated Waste Management Authority, assuming Richmond contributes to 50% of the waste disposed.
2. The percent of waste profile for each degradable waste type is the fraction of the total waste disposed made up by each type. 'Carpet' and 'Remainder/Composite Organics' waste streams are included in the Textile category due to waste stream definitions and available DOC/DANF data.
3. The percent degradable organic carbon (DOC) is the fraction of degradable carbon in each degradable waste type. Data for percent DOC is based on IPCC Guidelines.
4. The percent degradable anaerobic fraction (DANF) is the fraction of each degradable waste type that is capable of decomposition in anaerobic conditions. Data for percent DANF is based on California Air Resources Board data (Local Government Operations Protocol, V 1.1).
5. Represents the total carbon dioxide emissions plus methane emissions converted to carbon dioxide equivalents by a global warming potential factor of 21 based on 40 CFR 98 (emissions calculated per CalEEMod guidance). Emission estimates account for an oxidation efficiency of methane of 10% (per CalEEMod guidance), a destruction efficiency of landfill gas of 98% (per CalEEMod Guidance), and a collection efficiency of landfill gas of 75% (per 2005 Richmond GHG Inventory).

Abbreviations:

CCAR - California Climate Action Registry
CO₂e - carbon dioxide equivalent
DANF - Degradable anaerobic fraction
DOC - Degradable Organic Matter
