RICHMOND, CA 94804

TABLE OF CONTENTS

VOLUME 1: DRAFT ENVIRONMENTAL IMPACT REPORT (UNDER SEPARATE COVER)

VOLUME 2: DRAFT ENVIRONMENTAL IMPACT REPORT APPENDICES

APPENDIX 1	NOP AND COMMENT LETTERS
APPENDIX 3	OVERVIEW OF OIL REFINING PROCESS
APPENDIX 4.0	CUMULATIVE PROJECTS
APPENDIX 4.3	AIR QUALITY Appendix 4.3-CHRA Appendix 4.3-CST Appendix 4.3-EE Appendix 4.3-EI Appendix 4.3-HRA Appendix 4.3-MET Appendix 4.3-OP Appendix 4.3-PHYS Appendix 4.3-REG Appendix 4.3-SG Appendix 4.3-SHP Appendix 4.3-TRANS Appendix 4.3-URM
APPENDIX 4.5	CULTURAL RESOURCES – LETTERS
APPENDIX 4.8	GHG Appendix 4.8-BASE Appendix 4.8-CEI Appendix 4.8-CGRP Appendix 4.8-GOP Appendix 4.8-REG Appendix 4.8-SET
APPENDIX 4.10	CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS
APPENDIX 4.13	PUBLIC SAFETY Appendix 4.13-DET Appendix 4.13-OCA Appendix 4.13-PROG Appendix 4.13-REL
APPENDIX 4.16	TRAFFIC – TECHNICAL DATA
APPENDIX 4.17	WATER SUPPLY ASSESSMENT

APPENDICES TABLE OF TABLES

Table A4.0-1	Plans Considered as Part of the Chevron Refinery Modernization Project EIR Cumulative Impact Analysis	1
Table A4.0-2	Chevron Projects within or near the Project Site Considered as Part of the Chevron Refinery Modernization Project EIR Cumulative Impact Analysis	2
Table A4.0-3	Other, Non-Chevron Refinery and Pipeline Projects Considered as Part of the Chevron Refinery Modernization Project EIR Cumulative Impact Analysis	3

CHEVRON REVISED RENEWAL PROJECT
SEPTEMBER 1, 2011**

The purpose of this memorandum is to document and summarize the comments received during the public scoping period for the Chevron Revised Renewal Project Draft Environmental Impact Report (EIR).

Notice of Preparation

Pursuant to Section 15082 of the *CEQA Guidelines*, the City of Richmond circulated a Notice of Preparation (NOP) to the State Clearinghouse, public agencies, special districts, and members of the public for a public review period beginning June 10 and ending on July 12, 2011. The purpose of the NOP was to formally convey that the City, as the lead agency, was soliciting input regarding the scope and proposed content of the EIR. The NOP and all comment letters are provided as an appendix to this report.

Scoping Meeting

Pursuant to Section 15082 (c)(1) of the *CEQA Guidelines*, for projects of statewide, regional or areawide significance, the lead agency is required to conduct at least one scoping meeting. The scoping meeting is for jurisdictional agencies and interested persons or groups to provide comments regarding, but not limited to, the range of actions, alternatives, mitigation measures, and environmental effects to be analyzed in the Revised EIR. The City of Richmond hosted a scoping meeting at 6:00 p.m. on June 22, 2011, at the City Council Chambers, 440 Civic Center Plaza, Richmond, California. The scoping meeting was broadcast on ten occasions by KCRT between June 22 and July 24, 2011 and is available for viewing at the following URL: <http://www.kcrt.com/series/chevron-revised-renewal-project.html>.

NOP Scoping Responses

Eight verbal comments were received at the June 22, 2011 scoping meeting. Specific issues raised in the comments received are summarized in Table 1 below. Eight written comment letters were also received during the scoping period. Specific concerns raised in the written comments letters are summarized in Table 2 below.

All comments received during the scoping period will be taken into consideration during the preparation of the Draft Revised EIR.

Table 1: Summary of Scoping Meeting Comments

Commenter/Date	Summary of Verbal Comment
Judy Morgan President/CEO Richmond Chamber of Commerce June 22, 2011	The commenter made a statement in support of the project and requested an open and transparent process.
Dennis Roos June 22, 2011	The commenter made a statement in support of the project and requested an open and transparent process.
Tom Quinn Senior Field Representative Carpenters Union June 22, 2011	The commenter made a statement in support of the project; requested an open and transparent process; and expressed a desire for jobs.
Latrice Maderas Richmond BUILD Graduate June 22, 2011	The commenter made a statement in support of the project and expressed a desire for jobs.
Ken Morgan Insulators Local 16 June 22, 2011	The commenter made a statement in support of the project and requested an open and transparent process.
Dr. Henry Clark Director West County Toxics Coalition June 22, 2011	The commenter stated the following concerns: 1) confusion about the hydrogen pipeline in that the pipeline was going to start at the refinery but refinery would not be plugged into it because it would go to other refineries to supply hydrogen. 2) Safety along the pipeline at the refinery and in Richmond; if there is a problem along the pipeline, how will it affect other parts of the project or the refinery? 3) Toxic contaminants should not be increased or increased disproportionately. 4) Environmental justice laws must be followed. 5) Project needs to reduce emissions below current levels, otherwise the project will not meet requirements of environmental justice.
Paul Cohen President Carpenters Union June 22, 2011	The commenter: urged an expedited project/process, one that will pass muster and move forward; and encouraged the use of the analysis developed for the prior EIR and focus on issues of court decision to move forward. The commenter also expressed a desire for jobs and urged that the no project alternative considers the no jobs aspect.
Rafael Madrigal President 23rd Street Merchant Association June 22, 2011	The commenter made a statement in support of the project and expressed a desire for jobs.

Table 2: Summary of NOP Comments

Commenter/Date	Summary of Written Comment
<i>Public Agencies</i>	
Jean Roggenkamp Deputy Air Pollution Control Officer Bay Area Air Quality Management District July 19, 2011	Provide a discussion of the District's attainment status for all criteria pollutants and the implications for the region if these standards are not attained or maintained by statutory deadlines; a discussion of the health effects of air pollution, especially on sensitive receptors; and a discussion of greenhouse gas (GHG) emissions and the potential impacts from climate change in the Bay Area.
	Provide a map that identifies the distance between the Revised Project and all sensitive receptor locations, such as residences, schools, day cares, hospitals, and nursing care within 1,000 feet.
	Provide a detailed analysis of the Revised Project's potential effects on local and regional air quality from construction and operations (including permitted and non-permitted stationary and area emissions, and mobile emissions). The cumulative impacts for the Revised Project should also be evaluated.
	Estimate both the maximum daily and annual emissions of volatile organic compounds (VOCs), nitrogen oxides (NOx), greenhouse gases (GHGs) and particulate matter (PM2.5 and PM10).
	Estimate and evaluate the potential health risks from construction and operation activities to current and future sensitive populations within the Revised Project area from toxic air contaminants (TACs).
	Include mitigation measures for any identified potentially significant air quality impacts.
	Consult with the District's permit engineers to determine the appropriate baseline emissions for the Revised Project air quality analysis.
	Include a list of all equipment that would be part of the Revised Project, including abatement devices, and equipment makes and models
Linda Scourtis Coastal Planner San Francisco Bay Conservation and Development Commission July 8, 2011	Although it appears the project is located outside our "shoreline band" permitting jurisdiction, the Chevron Richmond Refinery is located within a water-related industry priority use area as shown on Bay Plan Map 4. Under the CZMA, in the event a federal permit or federal funding is needed for the proposed project, the Commission has the authority to determine whether the activity is consistent with its law and policies. If there will be any such federal involvement with the Energy and Hydrogen Renewal Project, the project proponent should contact Ms. Jaime Michaels of our staff.
Joseph G. Doser, REHS Supervising Environmental Health Specialist Contra Costa Health Services July 15, 2011	A permit from the Contra Costa Environmental Health Department is required for any well or soil boring prior to commencing drilling activities, including those associated with environmental investigation and cleanup, and geotechnical investigation.
	Any abandoned wells (water, environmental, or geotechnical) and septic tanks must be destroyed under permit from CCEHD.

Scott Wilson for Carl Wilcox Regional Manager Bay Delta Region Department of Fish and Game July 6, 2011	Provide a complete assessment (including but not limited to type, quantity, and locations) of the habitats, flora and fauna within and adjacent to the project area, including endangered, threatened, and locally unique species and sensitive habitats. The assessment should include the reasonably foreseeable direct and indirect changes (temporary and permanent) that may occur with implementation of the project. Rare, threatened, and endangered species to be addressed should include all those which meet CEQA definition (see CEQA Guidelines, Section 15380).
	Include an analysis of changes in nitrogen deposition rates associated with new operational procedures at the refinery.
	Include any related nitrogen deposition impacts on special-status plants in the vicinity of the project, such as increased competition from exotic plant species, should be discussed and addressed.
	A California Endangered Species Act (CESA) Permit must be obtained if the project has the potential to result in take of species of plants or animals listed under CESA, either during construction or over the life of the project.
	The CEQA document must specify impacts, mitigation measures, and a mitigation monitoring and reporting program.
	For any activity that will divert or obstruct the natural flow, or change the bed, channel, or bank (which may include associated riparian resources) of a river or stream, or use material from a streambed, DFG may require a Lake and Streambed Alteration Agreement (LSAA).
	The CEQA document should fully identify the potential impacts to the stream or riparian resources and provide adequate avoidance, mitigation, monitoring, and reporting commitments for completion of the agreement.
Gary Arnold District Branch Chief Local Development – Intergovernmental Review California Department of Transportation July 12, 2011	The project's fair share contribution, financing, scheduling, implementation responsibilities, and lead agency monitoring should be fully discussed for all proposed mitigation measures.
	Must include documentation of a current archaeological record search from the Northwest Information Center (NWIC) of the California Historical Resources Information System (CHRIS) at Sonoma State University if construction activities are proposed within State ROW. Current record searches must be no more than five years old.
	If it is determined that traffic restrictions and pedestrian/bicycle detours are needed, a Transportation Management Plan (TMP) or construction traffic impact study may be required by the developer for approval by the lead agency and the Department prior to construction.
	Project work that requires movement of oversized or excessive load vehicles on State roadways, such as Interstate 580 (I-580) requires a transportation permit that is issued by the Department.

Scoping Session Summary Report
Chevron Revised Renewal Project EIR

John L Rush for William R. Kirkpatrick Manager of Water Distribution Planning Division East Bay Municipal Utility District July 12, 2011	EBMUD determined that the revised project does not require the preparation of a new WSA as the revised project reduces the scope from the original project with the elimination of the co-generation facility and appears not to induce additional water demand from the original estimate. The reduction of water demand should be confirmed in the Draft EIR.
Katy Sanchez Program Analyst Native American Heritage Commission July 18, 2011	Contact the appropriate Regional Archaeological Information Center for a record search.
	Contact the Native American Heritage Commission for: ▪ A Sacred Lands File Check ▪ A list of appropriate Native American contacts for consultation
	Lack of surface evidence of archeological resources does not preclude their subsurface existence.
<i>Individuals</i>	
Linda Schneider, M.A. July 10, 2011	What specific steps will Chevron take to significantly move beyond current emission standards (more than 50%) and from gas and oil production into more green forms of production?
	How can Chevron participate in a community-wide, systemic change which is more beneficial to the overall environment and to the lives of individuals within the community and within Chevron's employ?

Memorandum

Date: June 14, 2011
To: All Reviewing Agencies
From: Scott Morgan, Director
Re: SCH # 2005072117
Chevron Revised Energy and Hydrogen Renewal Project

The State Clearinghouse distributed the above-referenced Notice of Preparation on June 13, 2011 to your agency for review and comment. It has come to our attention that the document was issued a previous State Clearinghouse Number in error. For all future correspondence regarding this project, please use the new State Clearinghouse Number **2011062042**. We apologize for any inconvenience this may have caused. All other project information remains the same.

**RE: New SCH Number for the Revised Energy and Hydrogen Renewal Project
Revised EIR**

The City of Richmond submitted a Notice of Preparation (NOP) for the Revised Energy and Hydrogen Renewal Project Revised Environmental Impact Report (EIR) on Friday, June 10, 2011. Upon receipt of the NOP, the State Clearinghouse (SCH) assigned the previous Draft EIR SCH Number (2005072117) to this project.

Please accept this letter as a request to assign a new SCH number for the Revised Energy and Hydrogen Renewal Project Revised EIR.

Please feel free to contact me at (510) 620-6841 or via email at Lina_Velasco@ci.richmond.ca.us with any questions.

Sincerely,

Lina Velasco

Re: Chevron Revised Energy and Hydrogen Renewal Project
SCH# 2011062042

Attached for your review and comment is the Notice of Preparation (NOP) for the Chevron Revised Energy and Hydrogen Renewal Project draft Environmental Impact Report (EIR).

Responsible agencies must transmit their comments on the scope and content of the NOP, focusing on specific information related to their own statutory responsibility, within 30 days of receipt of the NOP from the Lead Agency. This is a courtesy notice provided by the State Clearinghouse with a reminder for you to comment in a timely manner. We encourage other agencies to also respond to this notice and express their concerns early in the environmental review process.

Please direct your comments to:

Lina Velasco
City of Richmond
450 Civic Center Plaza
Richmond, CA 94804

with a copy to the State Clearinghouse in the Office of Planning and Research. Please refer to the SCH number noted above in all correspondence concerning this project.

If you have any questions about the environmental document review process, please call the State Clearinghouse at (916) 445-0613.

Sincerely,

Scott Morgan

Subject: Notice of Preparation of a Revised Environmental Impact Report State CEQA Guidelines § 15082(a)

Notice is hereby given that the City of Richmond will be Lead Agency and prepare a Revised Environmental Impact Report (Revised EIR) for the Revised Energy and Hydrogen Renewal Project (Revised Project) proposed by Chevron Products (Chevron) at the Chevron Richmond Refinery (Refinery). The City is requesting comments on the scope and content of this Revised EIR. The City will use the Revised EIR prepared for this project when considering approval of the Revised Project. Responsible agencies will need to consider the Revised EIR prepared by the City of Richmond when considering any permit or other approval for the proposed project.

Further notice is hereby given that a public meeting to receive comments on this Notice of Preparation and the scope of the Revised EIR will be held by the Richmond Department of Planning and Building Services on June 22, 2011, at 6 pm at the City Council Chambers, 440 Civic Center Plaza, Richmond, CA 94804. You may also submit written comments at the public meeting.

Chevron's Renewal Project was originally approved by the City in July 2008. However, following a court challenge, the EIR for the Renewal Project was found by the Court of Appeal to be insufficient under the California Environmental Quality Act (CEQA). On March 14, 2011, the Superior Court issued a writ of mandate setting forth the issues to be addressed in a Revised EIR. The Revised EIR is being prepared to meet the requirements set forth in the writ of mandate. In addition, Chevron has reduced the scope of the prior project by eliminating several components. The Revised EIR will consider the project as now proposed.

A description of the Revised Project, its location and the potential environmental effects are contained in the attached materials. The City has determined that an Initial Study is not required.

Your response must be received at the earliest possible date, but not later than July 12, 2011. Please send your response to Lina Velasco at the City of Richmond Department of Planning and Building Services at the address shown above. In your response, please include your name, the name of your agency or organization (if applicable), and contact information. The NOP and project file are available for review between the hours of 8:30 am to 5:00 pm, Monday through Friday at the City of Richmond Department of Planning and Building Services, Second Floor 450 Civic Center Plaza, Richmond CA 94804.

Project Title: Chevron Revised Project
Project Applicant: Chevron

Date: June 10, 2011

NOTICE OF PREPARATION CHEVRON REVISED PROJECT

1) Background

In 2005, Chevron Products (Chevron) proposed the Energy and Hydrogen Renewal Project at the Chevron Richmond Refinery (Refinery). The original project involved several modifications to the Refinery: (1) Hydrogen Plant Replacement; (2) Hydrogen Purity Improvements; (3) Power Plant Replacement; (4) Catalytic Reformer Replacement; (5) Associated Infrastructure Modifications; and (6) Other New and Replacement Facilities (storage tanks, control building and central maintenance building).

In July 2008, the City of Richmond (City) certified an environmental impact report (EIR) and issued conditional use and design review permits for the project. Construction of two project components, the Hydrogen Plant replacement and the Hydrogen Purity Improvements, commenced in 2008, but was halted in July 2009 when the Superior Court found the EIR to be insufficient. At that time, construction of these two components was more than 50% complete.

Following an appeal by Chevron, the Court of Appeal found the EIR to be insufficient, and set aside the permits for the project. The Court of Appeal declined to rule on whether the EIR's analysis of cumulative impacts was sufficient. On March 14, 2011, the Superior Court issued a writ of mandate setting forth the issues to be addressed in a Revised EIR in order for the City to reconsider the permits for the project.¹

On May 23, 2011, Chevron submitted an application to the City for a Revised Project, which reduces the scope original project. The Revised Project will complete only the Hydrogen Plant replacement and the Hydrogen Purity Improvements. It will also include the associated equipment needed to tie the improvements into the Refinery. The Catalytic Reformer Replacement, Power Plant Replacement, and Other New and Replacement Facilities that were part of the original project have been eliminated: The Catalytic Reformer Replacement and the Power Plant Replacement, which was to support the Catalytic Reformer, are no longer needed due to changes in the transportation fuel market. The Other New and Replacement Facilities (storage tanks, control building and central maintenance building) are no longer proposed for economic and other reasons.

Accordingly, the City is now preparing a Revised EIR that addresses the May 23, 2011 application. The Revised EIR will address requirements set out in the Superior Court's writ of mandate. In addition to the City permits, Chevron will seek to obtain an Authority to Construct from the Bay Area Air Quality Management District (BAAQMD) and comply with all applicable plans, rules and regulations of the BAAQMD in respect to air emissions from the Revised Project. The BAAQMD will serve as a responsible agency under CEQA and will rely on the Revised EIR for issuance of the Authority to Construct.

¹ A more detailed description of the City's prior permit proceedings and the court decision is provided in **Appendix A.**

2) Project Location

The Revised Project is located entirely within the boundaries of the existing 2,900 acre Refinery, at 841 Chevron Way in the City of Richmond, County of Contra Costa. As shown in **Figure 1**, the project is located in the central and northern portions of the Refinery and within the existing Refinery footprint. The Hydrogen Plant replacement would be installed in an area of the Central Yard referred to as the “Y”. This area is currently occupied with the partially constructed Hydrogen Plant. Construction of the Hydrogen Purity Improvements would occur within or adjacent to the Sulfur Recovery Units (SRUs) and Fluid Catalytic Cracker Feed Hydrotreater (FCCFHT).

Southeast of the Refinery, across Castro Street and Garrard Boulevard, are the residential communities of Atchison Village, Santa Fe and Iron Triangle. The Shields-Reid residential community lies toward the northeast. Further east are central and downtown Richmond. Parchester Village is located northeast of the Refinery and Point Richmond is located to the southwest. The Point San Pablo Peninsula and the San Francisco Bay form the western border and San Pablo Bay forms the northern boundary of the Refinery property.

The main portion of the Refinery lies within the City’s M-3 Heavy Industrial, Zoning District. The Refinery is bounded by the Chevron Richmond Marketing Fuels Terminal to the southeast, and Chevron Energy Technology Company to the south. The Revised Project components will be located a minimum of 5,000 feet from any residential uses.

3) Project Description

The Refinery processes crude oil blends, externally sourced gas oils, and natural gas into a variety of fuel and oil products. In addition to producing motor gasoline, jet fuel, diesel fuel, and lubricating oils, the Refinery produces industrial fuel oil, liquefied petroleum gas, sulfur, and other products, such as ammonia. The Refinery also produces steam, electricity, fuel gas, and hydrogen, primarily for its own use.

The Revised Project is proposed by Chevron for several reasons. It would allow the Refinery to process crude oil blends and externally-sourced gas oils with higher sulfur content, in order to continue producing competitive transportation fuels and lubricating oils. In addition, it would replace the Refinery’s existing hydrogen production facilities with a modern plant that is more energy efficient yields higher purity hydrogen, and has the capacity to produce more hydrogen.

Each of the Revised Project components is described below. **Appendix B** lists specific equipment changes for the Revised Project.

A. Hydrogen Plant Replacement

The Refinery’s existing Hydrogen Plant produces approximately 95% pure hydrogen, with 5% impurities. Chevron proposes the replacement plant in order to produce more than 99%-pure hydrogen while using less energy. The replacement plant will also increase hydrogen production capacity from 180 million standard cubic feet per day (SCFD) to 230 million SCFD, utilizing refinery fuel gas, natural gas, and some ammonia as feedstock. The new plant will have sufficient

capacity to meet the Refinery's needs and to enable the owner and operator of the Hydrogen Plant to export hydrogen to third-party customers, consistent with the original project.

Improving hydrogen purity will reduce the density of hydrogen streams in the Refinery. This will necessitate replacement or modification of existing refinery compressors to preserve their current operation and capacities. The replacements and modifications will also reduce compressor energy consumption. The Revised Project will also include the installation of low-NO_x burners on five process heaters to maintain compliance with the Refinery-wide NO_x emission limit in BAAQMD Regulation 9, Rule 10.

B. Hydrogen Purity Improvements (Sulfur Removal)

The Hydrogen Purity Improvements will enable the Refinery to process crude oil blends that contain up to approximately 3% sulfur. These improvements will also provide the Refinery with the flexibility to process more externally-sourced medium-high sulfur gas oils (containing 0.5% sulfur or more). This change is likely to result in the replacement of some low-sulfur gas oils by medium-high sulfur gas oils; however, the overall amount of feedstock and petroleum product output will be consistent the Refinery's current capacity. Chevron proposes equipment changes to recover the additional sulfur, which would then be sold as a product.

The primary equipment changes involved in the Hydrogen Purity Improvements are to: increase the capacity of the FCCFHT (from 65,000 to 80,000 barrels per day) in keeping with the potentially higher sulfur feedstock slate; enable sulfur removal from the recycle hydrogen stream of the FCCFHT; add a #6 Hydrogen Sulfide Amine Regenerator; and increase the sulfur recovery capacity of the Sulfur Recovery Units (SRUs) (from 600 to 900 long tons per day). Under the application, there will also be related modifications and additions of ancillary process equipment such as pumps, piping, heat exchangers vessels, tanks, instrumentation, off-plot interconnections and utilities.

C. Associated Infrastructure Improvements

To tie the new Hydrogen Plant and Hydrogen Purity Improvements into the existing Refinery, new pipe racks, piping, and utility infrastructure (including electricity, steam, fuel gas, process gas, water, instrumentation, process and storm sewer connections) will be installed.

4) Potential Environmental Effects.

The Revised EIR will consider potential environmental effects that may be associated with the Revised Project. The Revised EIR will also examine whether changes will occur in other Refinery operations as a result of the changes associated with the Revised Project (e.g., Hydrogen Plant replacement, the Hydrogen Purity Improvements). Consistent with the writ of mandate issued by the Superior Court, the analysis will focus on relevant resources identified in Appendix G to the California Environmental Quality Act (CEQA) Guidelines, including, but not limited to criteria air pollutants, toxic air contaminants, human health risks, water discharges, and GHG emissions.

Although the only physical change to conversion or treating units proposed by Chevron in the Revised Project is an increase in throughput capacity of the FCCFHT, the Revised EIR will

examine a range of foreseeable operating scenarios (e.g., different feedstocks and crude slates) for the full Refinery once the Revised Project is completed and analyze the range of potential environmental effects. This analysis of potential environmental effects will also consider the full Refinery, including refinery emergencies and flaring.

The Appeal Court decision held that the prior EIR: (1) was unclear and inconsistent as to whether the project will enable Chevron to process a heavier crude slate than it is currently processing; and (2) did not state a baseline for crude gravity in order to measure the potential for increased impacts from any changes in the crude oil slate due to the project. The Revised EIR will consider whether the Revised Project includes any changes that would enable processing crude oil blends with heaviness outside the range of the Refinery's current baseline operation, in the light-intermediate crude gravity range. It will also describe the crude slate used by Chevron in recent operations in order to define the operational baseline, and will analyze whether there would be any potential environmental impacts from processing a variety of crude blends that utilize the Refinery's existing capacity.

The Appeal Court decision also held that the City improperly deferred the formulation of GHG mitigation measures to a future, post-EIR process. The Revised EIR baseline and post-project GHG emissions will be calculated consistent with AB-32 requirements, and will identify specific measures to achieve a net-zero emissions standard for GHG emissions over the pre-Revised Project baseline.

The Superior Court decision indicated that the EIR's cumulative impacts analysis may be affected. Therefore, the Revised EIR will consider whether there will be potentially significant cumulative impacts from operation of the Revised Project or the Refinery as modified by the Revised Project.

Figure 1. Richmond Refinery Site Plan

NOTICE OF PREPARATION CHEVRON REVISED PROJECT

APPENDIX A - LEGAL BACKGROUND

On April 6, 2005, Chevron applied to the City of Richmond (City) for permits necessary to construct and operate the Energy and Hydrogen Renewal Project (Original Project) within existing manufacturing facilities at the Richmond Refinery (Refinery). The Original Project involved the replacement of existing equipment at four main process plants with newer technology and included the following components:

- Hydrogen Plant Replacement
- Hydrogen Purity Improvements
- Power Plant Replacement
- Catalytic Reformer Replacement
- Associated Infrastructure Modifications
- Other New and Replacement Facilities (storage tanks, control building and central maintenance building)

On July 17, 2008, the City certified an environmental impact report (Original EIR or EIR) and approved the permits for the Original Project. Following the City's issuance of the Notice of Determination (NOD) on August 5, 2008, and the issuance of an authority to construct by the Bay Area Air Quality Management District (BAAQMD) on September 19, 2008, Chevron proceeded with construction of the Hydrogen Plant Replacement and Hydrogen Purity Improvements. Construction of these components was more than 50% complete when, in July 2009, the project was halted under a writ of mandate and injunction issued by the Superior Court of Contra Costa County ("Superior Court") pursuant to the petition filed by Communities for a Better Environment, West County Toxics Coalition and Asian Pacific Environmental Network. Chevron appealed the Superior Court's ruling and in April 2010, the Court of Appeal issued a decision instructing the Superior Court to "enter a new and different judgment granting the petition for writ of mandate with regard to the EIR's failure to provide an adequate project description and its failure to define mitigation measures for greenhouse gas emissions, while denying mandate relief with regard to the claim of improper segmentation of a larger project." (*Communities for a Better Environment v. City of Richmond* (2010) 184 Cal.App.4th 70.)

In its decision, the Court of Appeal held that (i) the project description in the Original EIR was unclear and inconsistent as to whether or not the project would enable Chevron to process a heavier crude slate than it currently processes; (ii) the EIR did not establish a baseline for purposes of determining whether there would be any increased impacts from any changes in the crude slate processed at the Refinery; and (iii) the EIR improperly deferred the formulation of greenhouse gas mitigation measures to a future, post-EIR process. The Court of Appeal did not address the EIR's cumulative impacts analysis challenged by Petitioners on the basis that the analysis would likely be affected by a revised project description and greenhouse gas analysis.

As directed by the Court of Appeal, the Superior Court entered a final judgment and issued a writ of mandate (Writ of Mandate) on March 16, 2011, directing the City to set aside: (1) Resolution No. 93-08, under which the City Council certified the Original EIR and adopted findings and a mitigation monitoring and reporting program for the Original Project; (2) Resolution No. 94-08, under which the City Council upheld the Planning Commission's approval of the conditional use and design review permits for the Original Project, and (3) any additional permits, authorizations, and any and all other approvals for the Original Project. The Writ of Mandate also ordered that the City take no action in reliance on the EIR and permits until the City reconsiders its approval of the EIR, brings the EIR into compliance with the requirements of CEQA, and makes the EIR consistent with the Court of Appeal's decision. Additionally, the Writ of Mandate enjoins Chevron from engaging in any project activity until the City complies with the Writ of Mandate and issues new permits for the project.

**NOTICE OF PREPARATION
CHEVRON REVISED PROJECT**

Appendix B - Specific Equipment To Be Installed or Modified As Part of the Revised Project:

Component	Proposed Scope
Hydrogen Plant Replacement (construction 50% complete)	1. Construct new Hydrogen Plant, including hydrogen separation PSA units (2 trains) ² 2. Shut down existing Hydrogen Plant (2 trains) 3. Install hydrogen recovery PSA unit (1) 4. Shut down PSA section of the existing hydrogen recovery unit (1) 5. Construct new cooling water tower (1) 6. Construct new flare (1) 7. Construct a new Hydrogen Plant Control Room (1) 8. Upgrade Richmond Lube Oil Plant (RLOP) Area Compressors (4) 9. Upgrade Distillation and Reforming Area Compressors (3) 10. Install Steam Turbine Generator (1) 11. Install low-nitrogen oxides (NO_x) burners on existing TKN Hydrocracker³ furnaces (3) 12. Install low-NO_x burners on existing Poly (Polymer) Plant furnaces (2) 13. Upgrade Isomax Area Compressors (8) 14. Relocate electrical infrastructure and Refinery power cables (5) 15. Install communication cables (6)

2 The Revised Project includes one new stand-alone hydrogen recovery unit, a Pressure Swing Adsorption ("PSA") unit that recovers hydrogen from the feed to the new hydrogen plant before that feed is sent to the hydrogen plant. This is BAAQMD source S-4451. Each of the new hydrogen plants (S-4449 and S-4450) also includes a PSA unit after the reformer furnace to separate produced hydrogen from byproducts. These PSA units are considered part of each respective hydrogen plant, and are not considered separate units (i.e., they do not have a separate BAAQMD source number).

3 TKN is the trade name of a Hydrocracker at the Refinery.

Component	Proposed Scope
Hydrogen Purity Improvements (construction 57% complete)	1. Construct new Recycle Hydrogen Amine Contactor (1) for Fluid Catalytic Cracker Feed Hydrotreater 2. Refurbish and rename Fresh Amine Storage Tank T-2421 from T-2400 (1) (switched to Amine service from caustic) 3. Construct new Rich Amine Storage Tank T-2420 (1) 4. Construct new Amine Regenerator (1) 5. Upgrade Isomax Area Compressor (1) 6. Construct new Oxygen Storage Tanks (2) 7. Upgrade sour water processing 8. Construct new Acid Gas Scrubber (1) 9. Construct new Fresh Caustic Tank T-2440 (1) 10. Construct new Spent Caustic Tank T-2445 (1) 11. Modify existing Fluid Catalytic Cracker Feed Hydrotreater (1) 12. Modify existing Sulfur Recovery Units (3) 13. Install new sulfur loading rack (1) including option to replace or upgrade existing vent scrubber (1) 14. Install truck and railcar loading and unloading stations for amines, sodium bisulfite, fresh and spent caustic (5) 15. Install automated caustic dilution and delivery system (1)
Associated Infrastructure Improvements (construction 60% complete)	1. Construct P, Q, U, V, and W Pipe Racks from various plants to Hydrogen Plant for Refinery process gas, hydrogen gas and utilities (steam, instrument air, firewater, freshwater). 2. Install approximately 7 miles of new process and utility piping 3. Install or modify Refinery Electrical Infrastructure 4. Install or Modify Instrument and Communication Cables with Pipe-Way Structural Supports

Subject: Notice of Preparation for the Revised Energy and Hydrogen Renewal Project and Revised Environmental Impact Report

Dear Ms. Velasco:

Bay Area Air Quality Management District (District) staff reviewed your agency's Notice of Preparation (NOP) for the Revised Energy and Hydrogen Renewal Project (Revised Project) proposed for implementation at the Chevron Refinery in Richmond (Refinery). The Revised Project would include the development of a new Hydrogen Plant and other Hydrogen Purity improvements. The Hydrogen Plant replacement would allow the Refinery to increase hydrogen production from 180 million standard cubic feet per day (SCFD) to 230 million SCFD. The Hydrogen Purity improvements would enable the Refinery to process crude oil blends that contain up to approximately 3% sulfur.

Revised Project Background

In 2005, Chevron proposed the Hydrogen and Energy Renewal Project at the Refinery (Original Project). In 2008, the City of Richmond (City) certified an environmental impact report (Original EIR) and issued the necessary permits, and the District also issued an Authority to Construct, for the Original Project. In 2009, a Superior court ordered that the entitlements be set aside, and construction activities were stopped due to the aforementioned court order.

Chevron is now proposing to reduce the overall scope of the Original Project. The Revised Project would complete construction and make operational only the Hydrogen Plant replacement and Hydrogen Purity improvement (essentially sulfur removal/handling) portions of the Original Project. The Catalytic Reformer Replacement, Power Plant Replacement including a new Cogeneration Unit, and Other New and Replacement Facilities (e.g., storage tanks) that were part of the Original Project are not part of the Revised Project. The City will prepare a Revised EIR to comply with the court decision regarding the Original EIR and to address changes in the project proposed by Chevron that have reduced the overall project scope:

The Revised EIR will be prepared by the City as the Lead Agency for the purpose of considering conditional use and design review permits for the Revised Project.

Page 1 of 3

In addition, the project sponsor must obtain pertinent permits from the District and comply with all applicable plans, rules and regulations of the District in respect to air emissions from the Revised Project. In this capacity, the District is a responsible agency for CEQA purposes.

Revised EIR Analysis

The District has the following specific comments on the environmental analysis that should be included in the Revised EIR:

1. The Revised EIR should provide a discussion of the District's attainment status for all criteria pollutants and the implications for the region if these standards are not attained or maintained by statutory deadlines; a discussion of the health effects of air pollution, especially on sensitive receptors; and a discussion of greenhouse gas (GHG) emissions and the potential impacts from climate change in the Bay Area.
2. The Revised EIR should provide a map that identifies the distance between the Revised Project and all sensitive receptor locations, such as residences, schools, day cares, hospitals, and nursing care within 1,000 feet.
3. The District's *CEQA Air Quality Guidelines (May 2011)* provide guidance on how to evaluate a project's construction, operational and cumulative air quality impacts. You may download a copy from the District's web site at: <http://www.baaqmd.gov/Divisions/Planning-and-Research/CEQA-GUIDELINES.aspx>. The Revised EIR should provide a detailed analysis of the Revised Project's potential effects on local and regional air quality from construction and operations (including permitted and non-permitted stationary and area emissions, and mobile emissions). The cumulative impacts for the Revised Project should also be evaluated.
4. The Revised EIR should estimate both the maximum daily and annual emissions of volatile organic compounds (VOCs), nitrogen oxides (NOx), greenhouse gases (GHGs), and particulate matter (PM_{2.5} and PM₁₀). Emission estimates should be transparent and verifiable. These estimates should be compared to the significance thresholds in the *District's CEQA Air Quality Guidelines*.
5. The Revised EIR should estimate and evaluate the potential health risks from construction and operation activities to current and future sensitive populations within the Revised Project area from toxic air contaminants (TACs).
6. The Revised EIR should include mitigation measures for any identified potentially significant air quality impacts. The District's *CEQA Air Quality Guidelines* contains numerous mitigation measures for lead agencies to consider.
7. The City should consult with the District's permit engineers to determine the appropriate baseline emissions for the Revised Project air quality analysis.
8. The Revised EIR should include a list of all equipment that would be part of the Revised Project, including abatement devices, and equipment makes and models.

The District's CEQA website contains a number of tools and resources to assist lead agencies in analyzing environmental impacts. Available documents include guidance on quantifying plan level greenhouse gas emissions and risk and hazard screening and modeling guidance. Available tools can be viewed and downloaded at: <http://www.baaqmd.gov/Divisions/Planning-and-Research/CEQA-GUIDELINES/Tools-and-Methodology.aspx>

We encourage lead agencies to contact District staff to answer relevant questions and request additional assistance during the environmental analysis process. If you have any questions regarding these comments, please contact Alison Kirk, Senior Environmental Planner, 415-749-5169.

Sincerely,

Jean Roggenkamp
Deputy Air Pollution Control Officer

SUBJECT: Notice of Preparation (NOP) for the Revised Chevron Energy and
Hydrogen Renewal Project draft Environmental Report (EIR)
BCDC Permit File 11-90; SCH#: 201062042

Dear Ms. Velasco:

Thank you for the opportunity to comment on the Notice of Preparation (NOP) for the Revised Chevron Energy and Hydrogen Renewal Project draft Environmental Report (EIR). Although the San Francisco Bay Conservation and Development Commission (Commission) has not reviewed the document, the following are staff comments based on our review of the NOP in the context of the Commission's authority under the McAteer-Petris Act (California Government Code Sections 66600 et seq.) and the federal Coastal Zone Management Act (CZMA). The Commission exercises permitting authority over San Francisco Bay to the line of mean high tide, including all sloughs and marshlands lying between mean high tide and five feet above mean sea level. The Commission also has jurisdiction within a shoreline band between the edge of the Bay and a line 100 feet landward and parallel to the shoreline. Any person or government agency wishing to place fill, extract materials, or make any substantial change in use to any land, water or structure within the Commission's jurisdiction requires a permit from the Commission. The Commission can issue a permit if the proposed project is consistent with the McAteer-Petris Act and the provisions of the *San Francisco Bay Plan* (Bay Plan).

Additionally, the Commission designates certain shoreline areas for uses that must be located on the waterfront, such as ports and water-related industry (which includes the shipment of crude oil and related products via tanker or barge), so as to avoid potential filling of the Bay to accommodate water-related uses where the waterfront has been developed for uses that do not require a shoreline location. Although it appears the project is located outside our "shoreline band" permitting jurisdiction, the Chevron Richmond Refinery is located within a water-related industry priority use area as shown on Bay Plan Map 4. Under the CZMA, in the event a federal permit or federal funding is provided the proposed project, the Commission has the authority to determine whether the activity is consistent with its law and policies. If there will be any such federal involvement with the Energy and Hydrogen Renewal Project, the project proponent should contact Ms. Jaime Michaels of our staff.

Please contact me at 415.352-3644 or lindas@bcdc.ca.gov if you have any questions.

Sincerely,

LINDA SCOURTIS
Coastal Planner

RE: Notice of Preparation of a Revised EIR (Chevron Products Project – No Project
I.D. No. Provided)

Dear Ms. Velasco:

The Contra Costa Environmental Health Division (CCEHD) has received a request for agency comments for the above referenced project. The following are our comments:

1. A permit from CCEHD is required for any well or soil boring prior to commencing drilling activities, including those associated with environmental investigation and cleanup, and geotechnical investigation.
2. Any abandoned wells (water, environmental, or geotechnical) and septic tanks must be destroyed under permit from CCEHD. If the existence of such wells or septic tanks are known in advance or discovered during construction or other activities, these should be clearly marked, kept secure, and destroyed pursuant to CCEHD requirements.

These comments do not limit an applicant's obligation to comply with all applicable laws and regulations. If you should have any questions, please do not hesitate to call me at (925) 692-2535.

Sincerely,

Joseph G. Doser, REHS
Supervising Environmental Health Specialist

cc: Christina Bos, Environmental Health Specialist II

July 6, 2011

Ms. Lina Velasco
City of Richmond
450 Civic Center Plaza
Richmond, CA 94804

Dear Ms. Velasco:

Subject: Chevron Revised Energy and Hydrogen Renewal Project, Notice of Preparation, SCH #2011062042, City of Richmond, Contra Costa County

The proposed project consists of expansion and upgrades to an existing petroleum refinery in the City of Richmond, Contra Costa County. The following comments are submitted by the Department of Fish and Game (DFG) in response to a Notice of Preparation (NOP) released pursuant to the California Environmental Quality Act (CEQA).

Please provide a complete assessment (including but not limited to type, quantity and locations) of the habitats, flora and fauna within and adjacent to the project area, including endangered, threatened, and locally unique species and sensitive habitats. The assessment should include the reasonably foreseeable direct and indirect changes (temporary and permanent) that may occur with implementation of the project. Rare, threatened and endangered species to be addressed should include all those which meet CEQA definition (see CEQA Guidelines, Section 15380). DFG recommended survey and monitoring protocols and guidelines are available at [http://www.dfg.ca.gov/biogeodata/cnddb/pdfs/Protocols for Surveying and Evaluating Impacts.pdf](http://www.dfg.ca.gov/biogeodata/cnddb/pdfs/Protocols%20for%20Surveying%20and%20Evaluating%20Impacts.pdf).

The Environmental Impact Report (EIR) should include an analysis of changes in nitrogen deposition rates associated with new operational procedures at the refinery. Also, any related nitrogen deposition impacts on special-status plants in the vicinity of the project, such as increased competition from exotic plant species, should be discussed and addressed.

Please be advised that a California Endangered Species Act (CESA) Permit must be obtained if the project has the potential to result in take of species of plants or animals listed under CESA, either during construction or over the life of the project. Issuance of a CESA Permit is subject to CEQA documentation; therefore, the CEQA document must specify impacts, mitigation measures, and a mitigation monitoring and reporting program. If the project will impact CESA listed species, early consultation is encouraged, as significant modification to the project and mitigation measures may be required in order to obtain a CESA Permit.

Ms. Lina Velasco
July 6, 2011
Page 2

For any activity that will divert or obstruct the natural flow, or change the bed, channel, or bank (which may include associated riparian resources) of a river or stream, or use material from a streambed, DFG may require a Lake and Streambed Alteration Agreement (LSAA), pursuant to Section 1600 et seq. of the Fish and Game Code, with the applicant. Issuance of an LSAA is subject to CEQA. DFG, as a responsible agency under CEQA, will consider the CEQA document for the project. The CEQA document should fully identify the potential impacts to the stream or riparian resources and provide adequate avoidance, mitigation, monitoring and reporting commitments for completion of the agreement. To obtain information about the LSAA notification process, please access our website at <http://www.dfg.ca.gov/habcon/1600/>; or to request a notification package, contact the Lake and Streambed Alteration Program at (707) 944-5520.

If you have any questions, please contact Ms. Randi Adair, Environmental Scientist, at (707) 944-5596; or Mr. Liam Davis, Habitat Conservation Supervisor, at (707) 944-5529.

Sincerely,

Carl Wilcox

SCH# 2011062042

Ms. Lina Velasco
City of Richmond
450 Civic Center Plaza
Richmond CA 94804

Dear Ms. Velasco:

Chevron Energy and Hydrogen Renewal Project – Notice of Preparation (NOP)

Thank you for including the California Department of Transportation (Department) in the early stages of the environmental review process for the Chevron Energy and Hydrogen Renewal project. The following comments are based on the NOP. As the lead agency, the City of Richmond is responsible for all project mitigation, including any needed improvements to State highways. The project's fair share contribution, financing, scheduling, implementation responsibilities and lead agency monitoring should be fully discussed for all proposed mitigation measures. This information should also be presented in the Mitigation Monitoring and Reporting Plan of the environmental document. Required roadway improvements should be completed prior to issuance of the Certificate of Occupancy. Since an encroachment permit is required for work in the state right of way (ROW), and the Department will not issue a permit until our concerns are adequately addressed, we strongly recommend that the City of Richmond work with both the applicant and the Department to ensure that our concerns are resolved during the California Environmental Quality Act (CEQA) process, and in any case prior to submittal of a permit application. The Department appreciates the opportunity to submit comments to the NOP and additional comments may be forthcoming as the CEQA process progresses.

Cultural Resources

The project environmental document must include documentation of a current archaeological record search from the Northwest Information Center (NWIC) of the California Historical Resources Information System (CHRIS) at Sonoma State University if construction activities are proposed within State ROW. Current record searches must be no more than five years old. The Department requires the records search, and if warranted, a cultural resource study by a qualified, professional archaeologist, and evidence of Native American consultation to ensure compliance with CEQA, Section 5024.5 of the California Public Resources Code and Volume 2 of Caltrans' Standard Environmental Reference (<http://ser.dot.ca.gov>). These requirements, including

Ms. Lina Velasco/City of Richmond

July 12, 2011

Page 2

applicable mitigation, must be fulfilled before an encroachment permit can be issued for project-related work in State ROW; these requirements also apply to NEPA documents when there is a federal action on a project. Work subject to these requirements includes, but is not limited to: lane widening, channelization, auxiliary lanes, and/or modification of existing features such as slopes, drainage features, curbs, sidewalks and driveways within or adjacent to State ROW.

Traffic Management Plan

If it is determined that traffic restrictions and pedestrian / bicycle detours are needed, a Transportation Management Plan (TMP) or construction traffic impact study may be required by the developer for approval by the lead agency and the Department prior to construction. The plans shall be prepared in accordance with the Department's *Manual of Traffic Controls for Construction and Maintenance Work Zones*, which begins as follows: "During any time the normal function of a roadway is suspended, temporary traffic control planning must provide for continuity of function (movement of traffic, pedestrians, bicyclists, transit operations, and access to property/utilities)." Further information is available on the following website:
<http://www.dot.ca.gov/hq/traffops/signtech/signdel/trafficmanual.htm>.

Transportation Permit

Project work that requires movement of oversized or excessive load vehicles on State roadways, such as Interstate 580 (I-580) requires a transportation permit that is issued by the Department. To apply, a completed transportation permit application with the determined specific route(s) for the shipper to follow from origin to destination must be submitted to the address below.

Office of Transportation Permits
California DOT Headquarters
P.O. Box 942874
Sacramento, CA 94274-0001

Re: Notice of Preparation of a Revised Environmental Impact Report –
Chevron Revised Renewal Project, Richmond

Dear Ms. Velasco:

East Bay Municipal Utility District (EBMUD) appreciates the opportunity to comment on the Notice of Preparation of a Revised Environmental Impact Report (EIR) for the Chevron Revised Renewal Project located in the City of Richmond (City). EBMUD has the following comments.

GENERAL

EBMUD issued a Water Supply Assessment (WSA) response to the City on April 24, 2007 for the Chevron Energy and Hydrogen Renewal Project. The estimated water demand for the project was 0.7 million gallons per day and is accounted for in EBMUD's water demand projections within EBMUD's service boundaries. Upon reviewing the Notice of Preparation of the Revised EIR, EBMUD determined that the revised project does not require the preparation of a new WSA as the revised project reduces the scope from the original project with the elimination of the co-generation facility and appears not to induce additional water demand from the original estimate. The reduction of water demand should be confirmed in the Draft EIR.

WATER RECYCLING

EBMUD's Policy 9.05 requires that customers use non-potable water, including recycled water, for non-domestic purposes when it is of adequate quality and quantity, available at reasonable cost, not detrimental to public health and not injurious to plant, fish and wildlife to offset demand on EBMUD's limited potable water supply. Appropriate recycled water uses could include landscape irrigation, commercial and industrial process uses, toilet and urinal flushing in non-residential buildings and other applications.

EBMUD provided a written response to the Draft Environmental Impact Report on the original project (see enclosure) encouraging the use of recycled water for the project that would be supplied from the unfinished Richmond Advanced Recycled Expansion (RARE) project at the time. Since then, RARE has started operations as of July 2010, and currently supplies the Chevron Richmond refinery with up to 3.5 million gallons per

Lina Velasco, Senior Planner

Page 2

day (mgd) of recycled water for use as boiler feed water. Future phases of RARE could expand production up to 4.0 or 5.0 mgd of recycled water, depending on demand and the availability of secondary effluent supply. This represents additional opportunities for recycled water use for several purposes within the new revised project components and facilities. As such, EBMUD recommends that the City and Chevron continue to consult and coordinate with EBMUD to develop and expand the usage of recycled water at Chevron's Richmond Refinery as they plan and implement these specific projects as described in the revised EIR.

If you have any questions concerning this response, please contact David J. Rehnstrom, Senior Civil Engineer, at (510) 287-1365.

Sincerely,

A handwritten signature in black ink, appearing to read "William R. Kirkpatrick", with a stylized flourish at the end.

Re: Draft Environmental Impact Report – Chevron Energy and Hydrogen
Renewal Project, Richmond

Dear Mr. Thompson:

East Bay Municipal Utility District (EBMUD) appreciates the opportunity to comment on the Draft Environmental Impact Report (EIR) for Chevron Energy and Hydrogen Renewal Project located in Richmond. EBMUD has the following comments.

WATER RECYCLING

As described in the Water Supply Assessment issued to the City of Richmond on April 24, 2007 for the Chevron Energy and Hydrogen Renewal Project, EBMUD is committed to developing recycled water projects to conserve its limited drinking water supplies and reliably meet the long-term projected water needs of its customers. EBMUD's 1993 Water Supply Management Plan (WSMP) set a recycled water program savings goal of 14 million gallons per day (mgd) for the year 2020. EBMUD presently provides approximately 4 mgd of tertiary treated recycled water from its North Richmond Water Reclamation Plant for use in Chevron's cooling towers. As described on page 4.17-5, and again on page 5-9, of the EIR, EBMUD and Chevron are currently working together to implement the Richmond Advanced Recycled Expansion (RARE) Water Project by the end of 2009. The RARE Water Project would provide up to an additional 4 mgd of high-purity recycled water for use in Chevron's boiler feedwater applications. Combined, the two recycled water projects would meet over 50 percent of Chevron's total water use with recycled water.

The Chevron Energy and Hydrogen Renewal Project presents an opportunity to use high-purity recycled water from the RARE Water Project. EBMUD strongly urges Chevron to continue cooperating with EBMUD to develop the RARE Water Project to offset the increased water usage anticipated by the Chevron Energy and Hydrogen Renewal Project and increase Chevron's use of recycled water at the Richmond refinery.

RE: SCH# 2005072117 Chevron Revised Energy and Hydrogen Renewal Project; Contra Costa County.

Dear Ms. Velasco:

The Native American Heritage Commission (NAHC) has reviewed the Notice of Preparation (NOP) referenced above. The California Environmental Quality Act (CEQA) states that any project that causes a substantial adverse change in the significance of an historical resource, which includes archeological resources, is a significant effect requiring the preparation of an EIR (CEQA Guidelines 15064(b)). To comply with this provision the lead agency is required to assess whether the project will have an adverse impact on historical resources within the area of project effect (APE), and if so to mitigate that effect. To adequately assess and mitigate project-related impacts to archaeological resources, the NAHC recommends the following actions:

- ✓ Contact the appropriate regional archaeological Information Center for a record search. The record search will determine:
 - If a part or all of the area of project effect (APE) has been previously surveyed for cultural resources.
 - If any known cultural resources have already been recorded on or adjacent to the APE.
 - If the probability is low, moderate, or high that cultural resources are located in the APE.
 - If a survey is required to determine whether previously unrecorded cultural resources are present.
- ✓ If an archaeological inventory survey is required, the final stage is the preparation of a professional report detailing the findings and recommendations of the records search and field survey.
 - The final report containing site forms, site significance, and mitigation measures should be submitted immediately to the planning department. All information regarding site locations, Native American human remains, and associated funerary objects should be in a separate confidential addendum, and not be made available for public disclosure.
 - The final written report should be submitted within 3 months after work has been completed to the appropriate regional archaeological Information Center.
- ✓ Contact the Native American Heritage Commission for:
 - A Sacred Lands File Check. **USGS 7.5 minute quadrangle name, township, range and section required.**
 - A list of appropriate Native American contacts for consultation concerning the project site and to assist in the mitigation measures. **Native American Contacts List attached.**
- ✓ Lack of surface evidence of archeological resources does not preclude their subsurface existence.
 - Lead agencies should include in their mitigation plan provisions for the identification and evaluation of accidentally discovered archeological resources, per California Environmental Quality Act (CEQA) §15064.5(f). In areas of identified archaeological sensitivity, a certified archaeologist and a culturally affiliated Native American, with knowledge in cultural resources, should monitor all ground-disturbing activities.
 - Lead agencies should include in their mitigation plan provisions for the disposition of recovered artifacts, in consultation with culturally affiliated Native Americans.
 - Lead agencies should include provisions for discovery of Native American human remains in their mitigation plan. Health and Safety Code §7050.5, CEQA §15064.5(e), and Public Resources Code §5097.98 mandates the process to be followed in the event of an accidental discovery of any human remains in a location other than a dedicated cemetery.

Sincerely,

Katy Sanchez

Subject: EIR comments re Chevron renewed application

Hello Ms. Velasco,

After hearing Chevron representatives speak yesterday at a neighborhood council meeting in Parchester Village, and upon their asking for proposed questions, I would like to propose the following:

What specific steps will Chevron take to significantly move beyond current emission standards (more than 50%) and from gas and oil production into more green forms of production?

How can Chevron participate in a community-wide, systemic change which is more beneficial to the overall environment and to the lives of individuals within the community and within Chevron's employ?

Thank you.

Linda Schneider, M.A.

APPENDIX 3

Overview of Oil Refining Process

APPENDIX 3

OVERVIEW OF OIL REFINING PROCESS

This appendix provides a high-level, non-project specific description of the refining process as it generally occurs at the Chevron Richmond Refinery (Facility or Project site).

The refining process begins when *crude oils* or *externally sourced (purchased) gas oils* are delivered to the Facility as raw materials or feedstocks. These feedstocks are then refined in five main process steps:¹

- *Distillation* occurs when crude oil is separated by “distilling” into various components, called “crude oil fractions;”
- *Treatment* occurs when crude oil fractions are “treated” to remove sulfur and other natural impurities;
- *Cracking* occurs when molecules in the heavier crude oil fractions are divided by *cracking* these larger molecules into smaller molecular forms that can become transportation petroleum products;
- *Reshaping* (also called “reforming”) occurs when these molecules are “shaped” to meet the specifications for various kinds of products (e.g., octane levels in gasoline); and
- *Blending* occurs in the final product production process, when multiple hydrocarbon fractions are blended to meet the specifications for particular products (e.g., higher octane versus lower octane gasolines). *Blending* occurs

¹ While these five major steps in the refining process are described as discrete steps, not all hydrocarbon molecules in the refining process go through each of these steps, and some of these refining process steps are actually repeated in later refining steps. For example, the first step in the process, *Distillation*, describes the process of applying heat to crude oil to separate it into “fractions,” or separate streams of hydrocarbon molecules that boil at different temperature ranges. The fractions are then piped on to different refinery processing steps to produce different products. While the major distillation process occurs as the first step in the refining process at the crude unit (described in the *Distillation* step below), smaller distillation units also operate at several later stages in the refinery process. For example, the hydrotreating process (described in the *Treatment* step below) results in some cracking (described in the *Cracking* step below), and the cracked hydrocarbon output then is run through a fractionator (a type of distillation unit) to again separate this output into fractions as needed for the next processing steps.

when different products are piped into tanks and typically does not involve mechanical mixing.

The refining process as a whole is depicted in Figure A3-1, *Facility Process Diagram*. A description of the feedstocks processed by the Facility is provided below, followed by a description of each of these major processes.

3.1 FEEDSTOCKS

Crude oil is the Facility's primary “feedstock,” which is the raw material used to make refined petroleum products. A partially refined crude oil fraction called “gas oil” is also received by the Facility and is purchased from external sources (i.e., other refineries). Crude oil and gas oil are described below.

3.2 IMPORTANT CHARACTERISTICS OF CRUDE OIL

Crude oil is found deep beneath the earth's surface in natural underground reservoirs. Crude oil is believed to have been formed from a mixture of mud and very small plants and animals (algae and zooplankton) that lived in ancient seas and oceans millions of years ago. Crude oil was created from this mix through a combination of temperature, pressure, and time.

Crude oil is recovered primarily from oil extraction wells, and it is often temporarily stored near extraction areas before being transported (primarily by pipelines and ships) to refineries for processing. Unlike many other refineries in the United States, the Facility is not connected to crude oil supplies through pipelines. Instead, the Facility receives crude oil via tankers and barges that discharge at the Project site over the Long Wharf. Crude oil is stored in tanks at the Project site before being processed in the Facility.

Crude oil is not a single chemical compound. Instead, crude oil is a mixture of different chemical compounds, the vast majority of which include a combination of hydrogen and carbon atoms, and are thus called “hydrocarbons.” Other atoms, including nitrogen and sulfur atoms, can also be part of hydrocarbon molecules. Crude oil hydrocarbons may also contain small amounts of metals. Crude oil also typically includes small amounts of non-hydrocarbon contaminants, such as sediment, salt, and water.

The different hydrocarbon compounds in crude oil have different boiling points (the temperature at which liquids “boil”). Heating crude oil and condensing the heated vapors causes it to be physically separated into different streams of hydrocarbons (called “fractions”) through a simple distillation process (described further below).

What's Changing at the Chevron Refinery

The flow chart below illustrates the main process units and general process flow of the Chevron Richmond Refinery, highlighting what facilities and processes would either be built, replaced or altered in the Refinery Modernization Project. The vast majority of refinery functions will not be affected.

02.25.2014 P:\11-005 CVRN\PRODUCTS\DEIR\Figures\Apptx 8_Refinery 101\A3-1_FacilityProcessDiagram

Source: Chevron (T39r2)

Figure A3-1
Chevron Refinery Modernization Project EIR
Facility Process Diagram

One of the hydrocarbon fractions produced in the Facility's refining process is "gas oil," which is produced during the distillation process and various other processes. In addition to producing gas oil from crude oil feedstocks, Chevron imports surplus gas oil from other refineries. The Facility imports gas oil because it contains equipment that can refine more gas oil than what can be produced economically from its crude oil feedstock. In other words, the crude unit, the solvent de-asphalting unit (SDA unit, described below), and other process units that produce gas oil produce a smaller amount than later steps in the refinery processes can refine due to that equipment's greater capacity. Because a refinery's "efficiency" (also discussed in greater detail below) is directly linked to maximizing utilization of refinery equipment, Chevron imports purchased gas oil to efficiently utilize available Facility capacity.

3.2.1 Density or "Gravity" of Crude

"Density" is the amount of mass contained in a certain volume. The density of a crude oil is determined by the average weight (or "gravity") of its component molecules. "Heavy" crude oil is denser than "light" crude oil because the hydrocarbon molecules in heavy crude oil are larger and have more carbon atoms than those in light crude oil.² Atoms in a larger molecule are tightly bound together and take up less space than the same number of atoms spread out across multiple smaller molecules. Thus the atoms in heavy crude oil are more tightly packed together, taking up less space (volume) and making heavy crude oil denser than light crude oil.

Less dense (or "light") crudes generally have more light hydrocarbons, and light hydrocarbons are the constituents of higher-value refinery products such as gasoline, jet fuel, and diesel. Similarly, the denser ("heavier") crudes generally contain more of lower-value products like gas oil, tar, and bunker fuel commonly used in shipping.

When a refinery processes light crudes, higher-value products can be produced in fewer steps. For example, a light crude may only need to be "distilled" (the first step in the refinery process, described below) to produce large amounts of gasoline *blendstocks*. In contrast, a heavy crude may need to go through all of the refinery processes explained below (*Distillation, Treatment, Cracking*, and

² Heavy crude oil can also be denser than light crude oil because a higher proportion of the hydrocarbon molecules are in a denser form. (This characteristic is identified by the percentage of naphthenes in the crude.) Hydrocarbon molecules that are highly naphthenic can have molecules with the same number of carbon atoms, but those atoms are shaped like a circle rather than a straight chain. The circular structure is more dense than the straight chains.

Reshaping) to produce the same amount of gasoline or other light products. It should be noted that the *very* light hydrocarbons, at the other end of the gravity range, also have limited value. The ultimate light hydrocarbon is methane gas (CH_4), which is the primary component of natural gas. It can be quite a bit less valuable than even crude oil because natural gas is generally widely available. Therefore, the price paid for a “condensate” (a very light combination of hydrocarbons), can be less than a crude oil with significant mid-range hydrocarbon molecules.

The density or gravity of crude oil is important to the refining process in several ways. As mentioned above, when the mixture of compounds in crude oil is heated, lighter hydrocarbon compounds will begin to vaporize (turn into gas), and heavier compounds will not. As the temperature within this initial crude processing step is increased, heavier hydrocarbons will begin to vaporize.³ This physical characteristic of crude oil is key to the first step in the refining process: *Distillation*, in which crude oil (which has been desalted as described below) is heated in a furnace and sent to a large steel column to separate out the different hydrocarbons.

Different hydrocarbons boil at different temperature ranges and are grouped together in “fractions” based on these temperature ranges. The typical boiling temperatures of different fractions are shown in Figure A3-2, *Typical Boiling Temperatures (Cut Points) for Different Hydrocarbon Fractions*. Larger molecules contain more carbon atoms, are generally denser, and have a higher boiling point. Conversely, compounds with a lower carbon count are less dense and boil at a lower temperature.

For example, “gas oil” is the term used to describe the fraction of crude oil that is heavier than common refined products like gasoline, diesel, and kerosene or jet fuels—but lighter (less dense) than the heaviest fractions, which are called “residue” or “residuum.” Petroleum scientists devised a unique name for measuring the density, or weight, of a given hydrocarbon compound, called “American Petroleum Institute (API) gravity.” API gravity describes the density of a crude oil compared to the density of water. The lower the API gravity, the heavier the crude.⁴ The API gravity can be used to categorize crude as “heavy, intermediate, or light” as discussed in Section 4.0.3 of the *Chapter 4, Introduction to*

³ This is different from water—a single chemical compound of two hydrogen atoms and one oxygen atom, or H_2O —which would eventually all boil away into steam at the constant temperature of 212°F at normal pressures.

⁴ For comparison, water has an API gravity of 10 degrees. Generally, hydrocarbons with an API gravity above 10 degrees are lighter than water and will float.

Chapter and Methodology. Definitions for “light” and “heavy” crude oils are based on their specific gravity⁵ or API gravity.⁶ The following are generally accepted definitions for the crude oil gravities (CEC, 2006):

- **Heavy Crude.** Crude oils with API gravity of 18 degrees or less are characterized as heavy. The oil is viscous and resistant to flow, and tends to have a lower proportion of volatile components.
- **Intermediate Crude.** Crude oils with an API greater than 18 and less than 36 degrees are referred to as intermediate.
- **Light Crude.** Crude oils with an API gravity of 36 degrees or greater are referred to as light. Light crude oil produces a higher percentage of lighter, higher-priced premium products.⁷

3.2.2 Sulfur Content in Crude Oil

Another important natural characteristic of crude oil is that different types of crude oil have differing amounts of sulfur content. Sulfur occurs naturally in crude oil, but sulfur content is restricted by federal and State air quality laws in refined products (e.g., there are standards limiting the amount of sulfur that can be present in refined products like gasoline). To meet these regulatory restrictions on sulfur content in refined products, sulfur is removed from the various fractions of crude oil during the refining process.

When an oil has less sulfur, it is referred to as being “sweet.” Crudes with more sulfur are referred to as being “sour.” Although there is no regulatory threshold of sulfur content for dividing sweet crude oils from sour crude oils, oils with less than 0.5% sulfur content are generally referred to as “sweet.”

Most sulfur present in crude oil is bonded within hydrocarbon molecules, although some is present as hydrogen sulfide (H_2S) gas. This is different from “elemental” or pure sulfur (a yellow crystalline substance when at room temperature), which is a usable product. During the refining process, the sulfur

⁵ The specific gravity equals the weight of the compound divided by weight of an equal volume of water.

⁶ The API gravity, measured in degrees ($^{\circ}$), is defined as equal to $(141.5 \text{ divided by specific gravity}) - 131.5$. As a result, the higher the API gravity, the lighter the compound. Note that water has an API gravity of 10° , so any hydrocarbon crude with an API gravity greater than 10° is less-dense (lighter) than water.

⁷ These API breakpoint values are not applied universally. Other petroleum industry sources use varying breakpoints for heavy and light crude oils. The term “intermediate” is also used interchangeably with the term “medium” when referring to mid-range gravity crudes.

atom is removed from the hydrocarbon molecule. This process is called “hydrotreating” because it includes the use of hydrogen. The hydrocarbon fractions are combined with hydrogen in the presence of a catalyst and elevated temperatures and pressures. The catalyst, temperature, and pressure separate the sulfur from the hydrocarbon molecule and the sulfur combines with the available hydrogen to produce a gas called hydrogen sulfide (H_2S). This hydrogen sulfide gas is then treated, as explained below, to create “elemental” sulfur, which is sold as a product by Chevron. The Modernization Project includes several components to allow Chevron to remove more sulfur from the Facility's feedstocks and thereby refine higher sulfur crude oil and gas oil in the future.

3.3 CUTTER AND BLENDSTOCKS

In addition to feedstocks imported by the Facility for processing into transportation fuels and base oils, the Facility imports a small amount of blendstocks to be used in making final products that leave the Facility. The Facility imports two main types of blendstocks, a fuel oil blendstock called “cutter” and light product blendstocks, both of which are imported over the Long Wharf. Once on-site, blendstocks are not processed by the Facility, but rather serve as one of the components when mixing other Facility-produced blendstocks into finished products.

Cutter is used by the Facility to lower the viscosity of fuel oil product. The Facility has several process units that create material that can be used as cutter (e.g., cycle oil) and the Facility can always produce sufficient quantities to meet the Facility's overall cutter demand. As a result, cutter import is unrelated to refinery utilization. Nevertheless, there are times, such as when another facility has a surplus of cutter, in which the Facility may import material from other facilities (including other Chevron facilities) to be used as cutter instead of using internal sources.

Similarly, light product blendstocks can be imported, dependent on market conditions, into the Facility to supplement the various blendstocks or products that are produced by the Facility process units. These blendstocks (e.g., iso-octane) are used in the blending of finished products such as gasoline, but again are not used as feed to the Facility process units.

3.4 OVERVIEW OF THE REFINING PROCESS

3.4.1 Distillation: Separating the Fractions of Crude Oil with Heat

3.4.1.1 Crude Oil is First Pre-Heated and Treated to Remove Contaminants

Before crude oil goes through the first major step of the refining process, *Distillation*, it is preheated and treated to remove contaminants. First, the crude

oil is delivered on ships, pumped into holding tanks, and then pumped from those tanks to the crude unit. En route, the crude oil is heated in a series of “heat exchangers,” where heat from steam or already-heated product is transferred to the incoming cooler crude oil feedstock. (See below for a description of heat exchangers.)

Crude oil typically contains a small percentage of water and salts dissolved in the water. Because the salts are considered contaminants, after the pre-heating process the heated crude oil is next sent to a “desalter,” where these contaminants are removed. This protects the downstream equipment from potential plugging and corrosion mechanisms that can be associated with salts in crude oils.

A desalter is a large cylindrical vessel laid horizontally. The desalter removes contaminants from crude oil by first emulsifying (mixing together) the crude oil with wash water to promote thorough contact of the water and oil. The salts dissolve in this water phase. After the oil has been washed and mixed as an emulsion of oil and water, electrostatic fields are used to break the emulsion, separating the crude oil and water again (Johnson, 2014). The mixture of contaminants and water that has been separated from the crude oil is pumped into a wastewater treatment plant as described below.

Next, the crude oil is further pre-heated in heat exchangers and charged to a pre-flash tower. Light ends are flashed off (rapidly heated), and bypass the furnace. By pre-heating the feedstock and flashing off light ends, the process unit furnaces do not have to work as hard to heat the feedstock, saving energy. The remaining crude oil passes through a furnace where it is heated to a temperature of approximately 700°F. At this temperature, typically about half of the crude oil changes from liquid to vapor (see *Figure A3-3, Flow Diagram from Wharf to Crude Unit*). This combination of liquid and vapor is then ready for *Distillation*, the first major step in the refining process, described below.

3.4.1.2 The Primary Distillation Process Occurs in the Crude Unit

Distillation is the process of using heat to separate crude oil into different hydrocarbon streams by boiling point (called “cut points”). These separated “fractions” of crude oil are sent on to different parts of the Facility for further processing. Crude oil *distillation* occurs in the Facility's crude unit. The lighter compounds such as butane, gasoline, jet fuel, and diesel “boil off” (vaporize) at lower temperatures, and as the temperature increases, the heavier compounds such as gas oil vaporize last. The material that does not vaporize is referred to as “residuum.”

Typical Flow Diagram from Wharf to Crude Unit (Including Desalter, Heat Exchangers, Pipes)

A typical distillation schematic in Figure A3-4, *Distillation Schematic*, shows the separation of crude oil into fractions, from lighter at the top to heavier at the bottom. Figure A3-5, *Distillation Curve*, provides a typical distillation curve, showing volume and boiling temperatures (or “cut points”) for the various fractions of crude oil.

Crude oil fractions in the higher boiling point range require more complex equipment to process into transportation fuels and base oils that are in highest demand in the market. Crude oil fractions with lower boiling points still require further processing to meet finished product specifications, but typically require less complex refining. Figure A3-6, *Breakdown of a Typical Crude Oil Distillation Yield*, shows a typical breakdown of the composition of a barrel of crude oil according to the United States Energy Information Administration (EIA). Although this distillation process separates significant quantities of the lower boiling point fractions such as gasoline, by further refining the higher boiling point fractions, such as gas oils, more of the crude oil can be converted to desirable transportation fuels and base oils.

The crude unit is comprised of several pieces of equipment, as depicted in Figure A3-7, *Crude Unit Overview*, each of which is discussed below. The first distillation column in the crude unit at the Facility is the “atmospheric distillation column,” which is named “atmospheric” because the pressure in the unit is similar to the outside atmosphere. It operates on the physical principle of temperature to separate different hydrocarbon fractions and send them to different parts of the Facility for further processing. This is possible because, as discussed above, the different groups of hydrocarbon compounds or “fractions” found in crude oil have different boiling points.

Within the column, the vaporized hydrocarbons rise and the liquid hydrocarbons fall in a column consisting of perforated trays located at 24- to 30-inch intervals. The vapors rise through the perforations in the trays and bubble up through the liquids. As the vapors bubble up through the trays of liquid, some of the heavier (denser) hydrocarbons in the vapor condense (turn back into liquid) and collect on the trays. At several levels on the column, there are “side cuts” that drain liquid forms of hydrocarbons – with lighter products drawn off from the upper parts of the column and heavier liquids drawn from the trays closer to the bottom. Figure A3-8 below, *Distillation Column: Crude Oil Separation by Heat into Fractions* shows a typical separation of crude oil into these fractions, along with general boiling points of these fractions. Each fraction is then sent to different areas of the Facility for further processing.

Distillation Column: Crude Oil Separation by Heat into Fractions

As shown in the distillation curve in Figure A3-5 above, not all of the hydrocarbon fractions would have vaporized even at the highest temperatures reached in the atmospheric distillation column. A different process, called “vacuum distillation,” is used to help distill these heavier fractions by creating a vacuum condition, which is a pressure below atmospheric pressure. This decreased pressure allows the heavier fractions to boil at lower temperatures (just like water boils at a lower temperature in “thin air” that can be found at high mountain elevations) and be converted to vapor and separated.

At the Facility, this vacuum distillation process for separating the heaviest crude fractions is handled at a second distillation column, called the vacuum distillation column (see Figure A3-9, *Vacuum Distillation Process*), which is also part of the crude unit. The vacuum column construction is slightly different from the atmospheric column to minimize pressure loss in the column. The column includes several sections filled with “packing” material, sheets of metal or ceramic rings to allow the gas and liquid in the column to contact each other. There are trays in the column where light and heavy vacuum gas oil are drawn off. The bottoms from the column are residuum and are fed to the SDA unit (described below) to further separate the gas oil from the residuum.

The heaviest fraction from the vacuum distillation column, the residuum, goes through one more *separation* step before moving on to other processes. To remove the remaining gas oil from the residuum, the Facility uses an SDA unit. The SDA unit uses solvent to chemically dissolve the remaining gas oil molecules in the residuum. The gas oil and solvent mixture is sent to a column that operates at lower pressure. At the lower pressure, the gas oil separates from the solvent. The solvent is reused and the gas oil molecules are sent for further processing in the Facility's fluid catalytic cracker feed hydrotreater (FCC FHT) and fluid catalytic cracker unit (described below). The portion that is not absorbed by the solvent leaves the SDA unit as heavy residuum and leaves the Facility as a fuel oil blendstock product. The solvent is recycled back to the SDA process, where it is reused.

3.4.2 Treatment: Removing Sulfur and Other Natural Impurities

Hydrocarbons separated in the crude unit distillation process and SDA unit contain naturally occurring sulfur and other natural impurities such as nitrogen and metals. One of the key later steps in the refinery process involves chemical reaction processes that include a “catalyst” – a material that promotes or speeds up chemical reactions to produce either a finished product or another interim material to be processed further, such as in the *Cracking* step. These impurities can interfere with the *cracking* processes. In addition, they also reduce the quality and performance of finished transportation products and without

sufficient removal may not comply with finished fuel regulatory standards such as Ultra Low Sulfur Diesel and California's stringent “clean fuel” gasoline standards. The purpose of the *Treatment* step is to largely remove non-hydrocarbon components like sulfur, metals, and nitrogen. *Treatment* primarily occurs when the separated hydrocarbon fractions are sent to “hydrotreaters.” The Facility currently operates five hydrotreaters. Each hydrotreater processes different fractions of the crude oil. The diesel hydrotreater (DHT) treats diesel from the crude unit, the jet hydrotreater (JHT) treats jet fuel from the crude unit, and the gasoline hydrotreater (GHT) treats a gasoline product from the fluid catalytic cracker unit, a unit described in *Section 3.4.8* below. These three hydrotreaters—the GHT, DHT, and JHT—are “finishing” units that produce material used in fuel blending for finished products (see *Section 3.4.12* below).

The other two hydrotreaters, the naphtha hydrotreater and the fluid catalytic cracker feed hydrotreater (FCC FHT), primarily function as pre-treaters for petroleum fractions to be used as feeds to other units at the Facility for further processing before turning into finished products. The naphtha hydrotreater treats naphtha, a lighter-end fraction of crude oil distilled and routed from the crude unit to the naphtha hydrotreater. The FCC FHT treats gas oil from the crude unit and gas oil that is purchased from other refineries. The FCC FHT is labeled “FCC feed hydrotreater” because the gas oil it treats is primarily fed into the next unit in the process, called the fluid catalytic cracker, or FCC unit, which is involved in another step in the process, described below in *Section 3.4.8*. See hydrotreaters labeled in Figure A3-1, *Facility Process Diagram*.

3.4.3 Hydrotreating Removes Sulfur by Reacting Sulfur with Hydrogen to Create Hydrogen Sulfide

In the hydrotreating process, a hydrocarbon stream is fed through a furnace and the hot hydrocarbon and hydrogen gas are charged to a pressurized reactor that contains a catalyst, usually in a pellet form. The combination of catalyst, temperature, pressure, time, and hydrogen causes a chemical reaction in which the sulfur atoms on the hydrocarbon molecule are removed and hydrogen replaces them on the hydrocarbon molecule. The sulfur reacts with the free hydrogen to produce H_2S .

The hydrotreating process requires an excess amount of hydrogen to be present to ensure the greatest removal of the sulfur and nitrogen. Rather than allow the valuable excess hydrogen to be sent to the fuel gas system and burned as a refinery fuel, the excess hydrogen gas from the hydrotreaters is removed in a hydrogen separator and recycled to the process. The output from the reactor is charged to a fractionator to remove the light ends (which now include a

Chevron Refinery Modernization Project EIR
Vacuum Distillation Process

combination of usable hydrocarbons, hydrogen, and H_2S). The hydrotreating process is depicted in Figure A3-10, *FCC Feed Hydrotreating Process*.

As shown in the hydrotreating figure, the hydrotreating process relies on hydrogen. As discussed further below, hydrogen comes from four sources at the Facility. It is manufactured at the existing hydrogen plant, it is produced at the reformers, it is recycled when the unreacted hydrogen is recovered from the hydrotreating processes in the Facility, and it is also recovered from process gas through pressure swing adsorption (PSA).

The hydrotreating process occurring in the FCC FHT processing unit also results in some minor incidental cracking, where a catalytic reaction in the presence of hydrogen breaks heavier, longer chain hydrocarbons into lighter, shorter chains like gasoline and jet fuel (“light ends”). This hydrocracking (breaking longer hydrocarbon molecules into smaller ones in the presence of catalyst, temperature, pressure, and hydrogen) is a byproduct of the hydrotreating process. This same cracking phenomenon occurs in all of the hydrotreaters but is less pronounced in the lower pressure hydrotreaters including the NHT, GHT, JHT, and DHT. This “cracking” process is explained further in the next section, since *Cracking* is another major step in the refining process.

3.4.4 Hydrotreating Removes Nitrogen by Creating Ammonia

Similarly, nitrogen atoms on the hydrocarbon molecules are replaced by hydrogen in a chemical reaction, and the nitrogen reacts with free hydrogen to produce ammonia (NH_3).

Hydrocarbon outputs from the various units are frequently steam-stripped (i.e., contacted with steam) or water-washed (contacted with water). The condensed water from steam injected into the processes and water from the water washing process absorb ammonia and some H_2S that were produced in the various units. This water/ammonia/ H_2S mixture is charged to a vessel and some of the water is boiled off, yielding concentrated “sour water.” The ammonia and H_2S in the concentrated sour water are removed in sour water strippers that heat the sour water and separate the H_2S and ammonia from the water. The water from the sour water stripper is reused or sent to the water treatment facility. The H_2S stream is sent to the sulfur recovery unit. The ammonia is captured and stored for sale or used in the Facility.⁸

⁸ Ammonia can be used for removing NO_x from furnace stacks in a process called selective catalytic reduction, among other applications.

The FCC Feed Hydrotreating Process

The FCC Feed Hydrotreater (FCC FHT) is designed to remove metals as well as denitrify and desulfurize gas oils prior to being processed by the FCC unit. Some incidental "cracking" occurs during the hydrotreating process, creating a relatively small amount of lighter products such as gasoline blendstocks and jet fuel.

FCC Feed Hydrotreating Process

3.4.5 Amine Treatment Units Remove the Hydrogen Sulfide from Usable Hydrocarbons

As noted above, the *Treatment* step in the refining process also creates byproducts including H_2S that must also be managed. At the Facility, the H_2S gas created by the hydrotreaters is routed to a unit called an “ H_2S absorber,” which contains a solvent—diethanolamine (DEA)—designed to absorb the H_2S molecules and separate them from hydrogen and hydrocarbon gas streams. DEA liquid is mixed with the hydrogen sulfide rich gas in the H_2S absorber.

The H_2S absorber produces a liquid consisting of a mixture of H_2S and DEA, which is then piped to an “amine regenerator.” The amine regenerator is a vessel where a lower pressure plus heat added by a steam reboiler “flashes” off the H_2S . In the amine regenerator, the H_2S is stripped from the DEA. The DEA is recycled to be used again, and the H_2S gas (no longer containing hydrogen, hydrocarbons, or DEA) is then sent to a sulfur recovery unit, as described below (see Figure A3-11, *Amine Treatment Process*).

3.4.6 Sulfur Recovery Units Convert Hydrogen Sulfide H_2S Gas into Usable Elemental Sulfur

The separated H_2S stream is sent from the amine regenerator to one of three sulfur recovery units, where it is turned into elemental sulfur, using a process known as the “claus process” as depicted in Figure A3-12, *Sulfur Recovery Process*, below. Some H_2S is burned or oxidized in a furnace, creating sulfur dioxide (SO_2) from the H_2S ($H_2S + \frac{1}{2}O_2 = SO_2 + H_2O$). The SO_2 produced further reacts with the unreacted H_2S to produce elemental sulfur ($H_2S + \frac{1}{2}SO_2 = \frac{1}{2}S + H_2O$). The second step, which produces the elemental sulfur, occurs partially in the reactor furnace and partially in the catalytic reactors. The gases that exit the reactor furnace are routed to a heat exchanger where the elemental sulfur produced in the burner/furnace is condensed and sent to storage. The heat exchanger produces steam for use in the Facility. The gases from the heat exchanger are sent to a vessel that contains a catalyst to continue the conversion of the H_2S to elemental sulfur. The process at the Facility has two conversion stages to produce the majority of the elemental sulfur. The process gas that still contains unconverted H_2S is routed to the equipment called the Wellman-Lord tail gas recovery units, where remaining H_2S is oxidized to SO_2 and returned to the catalytic reactors for further conversion to elemental sulfur. The elemental sulfur that is produced is stored in a tank in a liquid form. It is shipped out of the Facility as a salable product in liquid form by truck.

Amine Treatment Process

An amine solution treats process gases containing hydrogen sulfide (sour gases) generated in the Facility's processing units. The treated gas is used within the Facility as a fuel source and the removed hydrogen sulfide is further treated into an elemental sulfur product.

3.4.7 Conversion: “Cracking” Remaining Heavy Hydrocarbon Molecules into Light Hydrocarbons

After hydrotreating to remove natural impurities including sulfur, many of the crude oil fractions processed by the Facility are suitable for *Blending* prior to sale as products (e.g., gasoline, diesel, jet fuel), or are ready to be blended into specialty products (e.g., lubricating base oils).

However, gas oil fractions must undergo an additional refining process—thermally or chemically “cracking” the long chains of hydrocarbon molecules that comprise these hydrocarbon fractions—to produce gasoline, diesel, and other high-demand petroleum products.

The Facility uses two types of “cracking” technology: catalytic cracking and hydrocracking.

3.4.8 Catalytic Cracking

The Facility's fluid catalytic cracking unit is the fluid catalytic cracker. Catalytic cracking, or “cat cracking,” involves heating gas oil fractions to temperatures of around 1,000°F when exposed to a “catalyst” at relatively low pressures (20 to 30 pounds per square inch [psi]) to “crack” the long chain hydrocarbon molecules into shorter chains, and thereby produce lighter hydrocarbons like gasoline. When the long-chain molecules of heated gas oil come into contact with the surface of the catalyst in this chamber, the molecular chains “crack” and become multiple, shorter-chained, lighter hydrocarbon molecules (see Figure A3-13, *Fluid Catalytic Cracking Process*).

The catalyst in the fluid catalytic cracker itself is a chemical compound with the appearance of a very fine powder. Although it comes into contact with the gas oil, the catalyst remains chemically unchanged and can be used again and again. The Facility's catalytic cracker is called a “fluid catalytic cracker” because the reaction takes place in a vessel where the catalyst particles behave like a liquid.

As the hydrocarbons crack, some of the carbon atoms from the cracked hydrocarbons deposit on the surface of the catalyst, which reduces the catalyst's ability to promote chemical reactions. (This deposit of carbon is often called “coking”.) To regenerate the catalyst, air is mixed with the catalyst in a heated environment, and a chemical reaction – the oxidation of coke (essentially burning) – takes place that removes the coke from the catalyst and allows it to be reused.

Fluid Catalytic Cracking Process

The Fluid Catalytic Cracker (FCC) Unit uses catalyst, which moves “fluidly” with the feedstock, to convert larger gas oil molecules into gasoline and other smaller hydrocarbons.

03.04.2014 P:\11-005 CVRN\PRODUCTS\DEIR\Figures\Appx 8_Refinery 101\Draft\CVRN Figure A3-13.pdf

Source: Chevron (T39r2)

Figure A3-13
Chevron Refinery Modernization Project EIR
Fluid Catalytic Cracking Process

The fluid catalytic cracker unit receives gas oil from (1) the hydrotreatment process described above, which removes sulfur and other natural impurities; and (2) imported purchased gas oil to the extent that it is already low in sulfur and thus does not require hydrotreatment.

3.4.9 Hydrocracking (TKN Isomax Unit)

The second method of cracking used at the Facility, *hydrocracking*, involves chemical reactions between hydrogen gas and hydrocarbons in the presence of a catalyst, and occurs in a vessel operated at very high pressures on the order of 1,000 to 3,000 psi. The Facility's hydrocracker is called a "TKN Isomax." Hydrocracking converts gas oil into lighter hydrocarbon fractions. Unlike cat cracking, hydrocracking does not produce significant coke because it adds hydrogen atoms to the cracked molecules instead of releasing carbon atoms. (Hydrogen is used in the TKN Isomax unit in this cracking process and is an example of a refinery process where hydrogen is used in a manner that is unrelated to sulfur.) See Figure A3-14, *The Hydrocracker Process*.

The hydrocracking in the Facility's TKN Isomax unit is a two-stage process that removes impurities from gas oil in the first stage and then "cracks" the gas oil in the second stage. The first stage is called the TKN (Taylor Katalytic DeNitrification). The second stage is called the Isomax. The name of the combined TKN Isomax is typically shortened to just "TKN" because essentially all of the material fed to the TKN is subsequently fed to the Isomax. The TKN unit receives the lighter gas oils produced by the crude unit and treats it to remove impurities, similar to the FCC FHT, which treats the heavier gas oils. The treated gas oil flows from the TKN to the Isomax where the gas oil is cracked into gasoline, jet fuel, and diesel.

The TKN *Treatment* stage removes impurities in a similar fashion as the hydrotreaters. Catalyst, temperature, pressure, and time remove the impurities and hydrogen reacts with sulfur, nitrogen, and hydrogen-deficient hydrocarbons producing H_2S gas and ammonia. As with hydrotreaters, the H_2S produced by the TKN is absorbed in a H_2S absorber by a DEA solvent for further treatment and recovery of elemental sulfur product through the amine regenerators and ultimately the sulfur recovery units. The TKN unit operates at temperatures and pressures that allow the sulfur and nitrogen in the gas oil feed to be converted to H_2S and ammonia for eventual recovery as either salable sulfur or ammonia product.

In the hydrocracking (Isomax) stage, a catalytic reaction in the presence of hydrogen cracks the bigger gas oil molecules into smaller gasoline, jet fuel, and diesel molecules. Since both units use hydrogen, there is some incidental

The Hydrocracker Process

A Hydrocracker unit uses hydrogen and catalyst to convert ("crack") larger hydrocarbon molecules into jet fuel, gasoline and other smaller hydrocarbons.

03.04.2014 P:\11-005 CVRN\PRODUCTS\DEIR\Figures\Appx 8_Refinery 101\Draft\CVRN Figure A3-14.pdf

Source: Chevron (T39r2)

Figure A3-14
Chevron Refinery Modernization Project EIR
The Hydrocracker Process

cracking in the TKN and there is some incidental removal of impurities in the Isomax.

Neither catalytic cracking nor hydrocracking creates or destroys hydrogen, carbon, nor any other atom. As larger hydrocarbon molecules are broken, they create larger numbers of smaller molecules. Those smaller molecules have the same molecular weight as the sum of the initial larger molecule plus the very light hydrogen gas, but the smaller molecules collectively take up more space (or volume) than the initial, larger, more dense molecule from which they were created. This expansion of volume through the hydrocracking process is called “processing gain” and it results in production (by volume) of slightly more hydrocarbon lighter end products than the volume of gas oil introduced to hydrocracker units. U.S. refinery processing gain averaged about 6.2% from 1996 through 2010. In 2012, about 44.98 gallons of refined products were produced for every 42 gallon barrel of oil input into U.S. refineries.

3.4.10 Reforming: Increasing Octane Levels in Gasoline

Reforming is a process primarily designed to increase the “octane” of gasoline. Octane is a characteristic of gasoline related to the tendency to “self-ignite” under pressure.⁹ Engines are rated based on their ability to run lower- or higher-octane gasolines. High-performance engines generally need higher-octane gasoline. If the octane level in the gasoline is not suitable for the engine, premature ignition of the gasoline occurs in the cylinder—a condition known as “engine knock” because of the knocking sound that is made when the gasoline ignites too early in the engine's compression stroke. Octane ratings in commercial gasoline range from about 85 anti-knock index (AKI) in regular gasoline in high altitudes like Denver, Colorado, to over 100 for aviation gasoline.

Severe knock causes severe engine damage, such as broken connecting rods, melted pistons, and melted or broken valves and other components. An octane rating is a measure of how likely a gasoline or liquid petroleum fuel is to self-ignite. The higher the number, the less likely an engine is to pre-ignite and suffer damage. California allows a range of octane levels at the pump (87, 89, and 91), and buyers can choose the octane level that is appropriate for their car and budget. Higher octane ratings are typically recommended for higher-performance engines, and higher octane levels also cost more per gallon at the retail level than lower octane levels.

⁹ Octane is also a name for some hydrocarbons that include eight carbon atoms.

The “reforming” process in the Facility takes hydrocarbons that are in the naphtha weight range but have low octane and changes their molecular structure into higher-octane gasoline molecules. The reforming process involves reshaping because the naphtha has the same number of carbon atoms before and after this part of the refinery process, but the molecules are “reshaped” into higher-octane gasoline molecules. This reshaping of molecules also releases hydrogen, which is then used in other Facility processes as part of the Facility's overall hydrogen supply.

The Facility has two catalytic reformer process units (#4 and #5 Rheniformer), each of which consists of four separate catalytic reactors. As with other refinery processes using catalysts, each of these reactors consists of a chamber containing the catalyst material, operated at controlled temperature and pressure levels. Naphtha from the naphtha hydrotreater (which removed sulfur from this naphtha hydrocarbon fraction) is fed through each reactor chamber in series. The feed is treated with perchloroethylene, a chemical that provides chloride atoms to control reforming catalyst activity.

The products of reforming are light gases and a high-octane gasoline component typically called reformate. Hydrogen gas, a by-product generated in this process, is recovered and used in other Facility processes. The light ends produced at the reformer are used in gasoline blending (normal butane), alkylation unit (iso-butane), liquefied petroleum gas (propane) or refinery fuel gas (methane or CH₄). The reformers at the Facility are “semi-regenerative,” which means that they accumulate coke as hydrocarbons are passed over them and a small amount of cracking occurs. This coke must be burned off periodically, which is called “regeneration.” The frequency of the regeneration depends on the octane level achieved for the reformate. Higher octane results in more frequent regeneration. Typical regeneration cycles are every 6 to 24 months and regeneration only takes a few days, unless significant other work is required on the unit.

3.4.11 Specialty Operations: Lubricating Base Oil Production Process

The Facility is also a major national producer of industrial lubricant base oils. This requires a specialty process consisting of gas oil hydrocracking. Gas oil from the crude unit is routed to the lube unit crackers. These are similar in operation to the FCC FHT, but instead of producing a primary output of gas oil for use in the fluid catalytic cracker, they produce material used as input to the lube hydrofinishers. The lube hydrofinishers also use hydrogen to treat this material and ultimately produce a base oil that is the primary building block in producing lubrication oil with the desired physical properties such as viscosity and density.

The base oil production process includes sulfur removal from the feed. The sulfur removal process is the same as the other hydrotreating units. Lighter ends that include H_2S produced in the lube crackers are directed to a H_2S absorber to remove the H_2S by absorption in DEA. The H_2S rich DEA is regenerated in an amine regenerator and the H_2S is changed to elemental sulfur in the sulfur recovery unit.

3.4.12 Blending and Final Product Production Process

The Facility processes produce hydrocarbon fractions that are products ready for shipment, and it also produces hydrocarbon fractions that require blending with other hydrocarbon fractions before being ready for shipment as products.

Blending typically occurs when hydrocarbon fractions are piped to a tank in specific quantities until required product specifications are achieved. All of the Facility's hydrocarbon products are produced either by one or more of the refinery process steps described above, or by blending hydrocarbons produced by one of the refinery process steps described above. How much of any particular product is produced varies based on market factors, but the Facility has consistently served as a primary supplier of gasoline, jet fuel, and base oils in the region.

3.5 OTHER REFINING PROCESS OPERATIONS

The Facility also includes other major equipment and activities that are integral to Refinery Operations but not technically part of the Facility's process for producing products. Other major categories of Refinery Operations described in this section include the Facility's hydrogen plant, furnaces, flaring system, power plant, wastewater treatment plants, and storage tanks.

3.5.1 Hydrogen Plant

As described above, hydrogen plays a critical role in the refinery process steps described above, including in the catalytic processes for removing sulfur in the *Treatment* processes, breaking bonds and forming new bonds in the *Cracking* processes, and the production of lubricant base oils. Hydrogen gas is produced on-site in an existing hydrogen plant as well as from the *Reshaping* process.

3.5.2 Hydrogen Manufacturing Technology

The current hydrogen plant produces hydrogen from a process known as “steam reforming.” The chemistry of the existing plant is relatively simple. Water (H_2O) is combined with methane (CH_4 , the primary component of natural gas) which, through a chemical reaction, produces hydrogen, carbon dioxide (CO_2), and carbon monoxide (CO). This steam reforming reaction is typically carried out using a nickel catalyst, which is packed into tubes of a reforming furnace.

In the mid-1980s, PSA generally replaced the older technology (Meyers, 2004). As explained further below, the primary difference between the two processes is that the final product from the steam reforming process described in the prior paragraph (about 94% pure hydrogen) goes through an additional step in the newer technology in which it is sent to PSA vessel units, where the hydrogen is selectively absorbed at high pressure, leaving the impurities like CO₂ behind. The absorption mixture is depressured, and very pure (99%) hydrogen is all that is left. The impurities and some hydrogen left in the PSA units are burned in the furnace to provide heat for the reaction.

3.5.3 Furnaces, Burners, Heat Exchangers and Thermal Oxidizers

Heating devices provide heat to various liquid or gas streams such as water, process streams (e.g., crude oil), or air. In general, these heating devices are referred to as “furnaces.” Sometimes, heating devices are given special names based on the stream being heated. For example, a heating device that boils water is commonly referred to as a “boiler.” A heating device that provides heat to non-water liquid streams is sometimes also referred to as a “process heater.” However, the general operation and the emissions associated with each are similar in concept.

These heating devices all include burner assemblies. The burners are where fuel (i.e., natural gas or refinery fuel gas) is combusted with oxygen to form a flame and hot combustion gases. (This is a larger scale version of the burners that one would find on a natural gas kitchen stove.) There are different ways a hydrocarbon stream may be heated during the refining process, depending on the configuration of the heating device and the technology of the refining process that the heating device serves. For example, a hydrocarbon stream being heated may pass through tubes that are surrounded by the hot combustion gas. In this case, the heat from the hot combustion gas transfers through the tube, increasing the temperature of the hydrocarbon stream within the tube. The flame component of the heating device may also be near the hydrocarbon stream, which would directly transfer additional radiant heat to the stream through the tubes.

In certain process units, burners are used to directly combust a refinery process stream (i.e., the material being processed through the Facility unit comes into direct contact with the flame from the burner) instead of using burners just as heaters. This occurs, for example, when hydrogen sulfide gas is combusted as part of the sulfur recovery unit process in the *Treatment* process for sulfur removal.

In addition, some burners are designed to combust volatile organic compounds (VOCs) in exhaust streams or fugitive emissions, converting the VOCs into CO₂ and water. Such devices are called thermal oxidizers. Thermal oxidizers are used, for example, to control VOC emissions from pumps and compressor seals at the Facility.

The combustion process for all heaters produces air emissions. The pollutants produced depend on the chemical composition of the fuel and combustion air and can include criteria air pollutants, toxic air contaminants, and greenhouse gases. The design of the device can influence the extent to which air emissions are generated. For example, low-NO_x burners are designed to reduce NO_x formation by controlling fuel and air mixing. Air emissions from burners are described in *Section 4.3, Air Quality*, and *Section 4.8, Greenhouse Gases*.

The combustion gas from a heating device typically remains hot even after transferring heat to the material being refined in the part of the refinery process served by the heating device. This combustion gas can be released as exhaust through a flue stack (subject to required air pollutant controls), or an “economizer” can be used to recover heat from the exhaust gas that would otherwise be released into the atmosphere. The recovered heat can be reused in the refining process to pre-heat a process stream or combustion air, which then results in lower fuel consumption because less fuel is used to bring the stream or combustion air up to operating temperature. An economizer is essentially a “heat exchanger” (described below) that reduces fuel consumption from the same device from which it derives its waste heat. The waste heat from the combustion gas could also be used to heat other streams derived from other units in a conventional heat exchanger.

A “heat exchanger” is a piece of equipment whereby a hotter process stream transfers heat to a cooler process stream. The two process streams do not come into direct contact with each other (i.e., they are not mixed). Rather, they are generally separated by a metal wall that conducts the heat from one stream to another. Heat exchangers are designed such that the surface area of the wall separating the two streams is maximized in order to maximize the amount of heat transferred. There are no emissions associated with heat exchangers because there is no combustion occurring. For example, the hot gases that exit the sulfur recovery unit enter into a heat exchanger where it transfers heat to a stream of water, converting the water to steam.

3.5.4 Flares

A refinery moves raw materials through a network of pipes and processing equipment. As described above, many of the refining processes involve using pressure and/or heat to change hydrocarbons and transporting heated or

pressurized hydrocarbons through the different parts of a refinery. Flare systems are designed to provide for the safe disposal of hydrocarbons that are either automatically vented or manually drawn from process units at refineries. Hydrocarbons must be controlled in a safe and effective manner in the event of an operational upset. Flare systems gather vented gases and combust them to prevent releases of hydrocarbons directly into the atmosphere.

Flaring plays a critical safety role in refinery operations. A “flare” is usually a tall stack equipped with burner equipment that is designed to ignite hydrocarbon gas when it leaves the flare. This flare technology is designed to very quickly and very efficiently consume hydrocarbon gas (similar to a gas stove), with minimal air pollution. The primary function of the flaring system is to relieve pressure to prevent units from overpressure. Flares are primarily used for burning off flammable gas released by a “relief gas header” during either unplanned pressuring of refinery equipment, or during startups and shutdowns. A header for collection of vapor streams is included as an essential element of nearly every refinery process unit. At the Facility, these are typically referred to as “relief gas headers,” since the system, which is generally at near-atmospheric pressure conditions, receives gases “relieved” from higher pressure operations within the unit.

The primary function of the relief gas header is safety. It provides the process unit with a readily available and controlled means of releasing gases to prevent over-pressurization of equipment (routing them to controlled locations for destruction by combustion). It also provides a controlled outlet for any excess vapor flow, nearly all of which is flammable and can be sent to a flare to be burned off, making it an essential safety feature of every refinery. Each relief gas header has connections for equipment depressurization and purging related to maintenance turnaround, startup, and shutdown, as well as pressure relief devices and other safety control valves to handle upsets, malfunctions, and emergency releases.

The Bay Area Air Quality Management District (BAAQMD) has been a global leader in regulating the use of flares. Flaring is not required to operate a refinery's process units during normal operation, and the need for flaring at the Facility has been substantially reduced over time.

The Facility has identified situations or activities likely to cause flaring, including releasing gases to prevent equipment from becoming over pressured, as described below in more detail. Releases of relief gas to the flare result from an imbalance between the quantity of vent gas produced by the Facility and the rate at which it can be compressed, treated to remove contaminants (sulfur compounds), and utilized as fuel gas. Situations that can lead to flaring can be

grouped together based on similarity of cause. At the Facility, flares are used for three primary purposes:

- **Process unit startups and shutdowns and planned maintenance.** To prepare an individual equipment item or a block of refinery equipment for maintenance, it is necessary to isolate it from active operations and clear it of process fluids. Examples include unit shutdowns, working on equipment and/or relief systems, catalyst change, plant leak repairs, and compressor maintenance or repairs. In order to avoid flaring, there must be a balance between producing and consuming fuel gas units. When either a block of equipment or an individual equipment item is removed from service, if it either produces relief gases or consumes fuel gases, then the balance of the fuel gas system is changed and adjustments are necessary to bring the system back into balance. If the net change in gas production or consumption is large and the adjustments in the rate at which gas is produced or consumed by other units cannot be made quickly enough, then flaring results.
- **Upset/malfunction.** An imbalance in the flare gas system can also result from upsets or equipment malfunctions that either increase the volume of flare gas produced or decrease the ability of the fuel gas handling system to accommodate it. Examples include relief valves lifting, pressure relief valve malfunction, equipment overpressure, loss of a utility system, and loss of air fins or condensers.
- **Emergency relief.** Pursuant to BAAQMD Regulation 12, Rule 12, Section 201, an emergency “is a condition at a petroleum refinery beyond the reasonable control of the owner or operator requiring immediate corrective action to restore normal and safe operation that is caused by a sudden, infrequent and not reasonably preventable equipment failure, natural disaster, act of war or terrorism or external power curtailment, excluding power curtailment due to an interruptible power service agreement from a utility.”

To address these situations, the Facility currently operates two flare gas systems, complete with flare gas recovery systems, one covering the “north yard” of the Facility and the other covering the “south yard.”

The operation of the Facility’s flare systems is governed by its flare management plan (FMP) submitted pursuant to the requirements of BAAQMD Regulation 12, Rule 12 (Reg. 12-12). The purpose of this rule is to reduce emissions from flares at petroleum refineries by minimizing the frequency and magnitude of flaring. Flaring is prohibited unless it is consistent with an approved FMP. Each refinery is required to submit a FMP annual update. The FMP defines a series of measures intended to reduce flaring to the extent that is feasible without compromising

safety and necessary refinery operations and practices. It is the Facility's policy that flare events would only occur within the scope of Reg. 12-12, and it would adjust the operation of process units or implement corrective action to prevent flaring in accordance with the regulation.

3.5.5 Power and Steam Generation, Including Boilers

The Facility is designed to generate on-site most of the power it needs to operate. During the baseline period of 2008-2010, the Facility imported an annual average of only 2 megawatts (MW) of electricity, compared to a total annual average of approximately 115 MW of electricity used by the Facility.

Electric power is generated at the Facility by two gas turbines, one steam turbine generator, and the fluid catalytic cracker power recovery system. The gas turbines generate electricity through the combustion of fuel which moves the blades of a turbine, providing mechanical power to operate the electric generator.

A steam turbine generator creates electricity when higher pressure steam is reduced to lower pressure steam, resulting in mechanical power to operate the electric generator. Steam is produced by two heat recovery steam generators at the co-generation unit as well as five fired boilers in the "No. 1 Power Plant."¹⁰ (The combination of the gas turbines, the heat recovery steam generators, and the duct burners comprise the co-generation facility.)

Steam is also generated by process units throughout the Facility. For example, steam is generated in a heat exchanger that takes in hot gases from the sulfur recovery unit, transfers the heat to a water stream, and converts that water to steam. In addition to being used to generate electricity in the steam turbine generator, steam is also piped throughout the Facility and is injected into various processing equipment to be used for heating in the refining process (similar to radiator heat in a house) or for direct contact with hydrocarbons during the refining process.

The Facility uses approximately 2.5 million pounds of steam per hour. However, the boilers in the No. 1 Power Plant generate only about 10% of that amount; the remaining steam is produced by refinery processes.

¹⁰ The five boilers are called the "No. 1 Power Plant" because the unit was built in the 1930s and used to generate electricity. However, "power plant" is a misnomer as the unit today consists of boilers only and generates only steam, not electricity.

3.5.6 Cooling Towers

Process streams require cooling that is usually provided by water in a heat exchanger. Water that picks up heat in the process is sent to a cooling tower where the water is dispersed into thin streams through which air is passed. The air evaporates a small amount of the water and the evaporation cools down the water, which is then pumped back to the heat exchanger again for reuse.

3.5.7 Water Use and Treatment

The refining process results in industrial wastewater that is treated in a wastewater treatment facility. The Facility's process wastewater and most of the stormwater runoff is collected and managed in the Facility's existing industrial wastewater treatment system that is regulated by the RWQCB.

3.5.8 Storage Tanks

The Facility currently operates approximately 160 aboveground storage tanks (including pressurized spheres) containing raw materials, feedstocks, intermediate material, and final products. There are a number of small/auxiliary tanks located throughout the Project site that are not part of the primary Refinery Operations processes.

Most tanks store raw feedstocks (crude oil and gas oil), intermediate stocks, or finished products (gasoline, diesel, jet fuel, etc.). These tanks are located in areas of the Facility known as the Refinery Process and Tank Farm areas (see *Figure 3-2 in Chapter 3, Project Description*). Furthermore, some tanks store chemicals that are involved in Refinery Operations but are neither feedstocks nor product, such as perchloroethylene used in the reforming process.

The tanks range in capacity from under 1,000 barrels to over 650,000 barrels. Over long periods of time (e.g., annually) the average amount of material stored in tanks is approximately constant, but the quantity of material flowing through the tanks on any given day increases or decreases as the feedstock tanks are emptied into the Facility (or product is produced by the Facility feed rate and production volumes change).

3.5.9 Pipelines, Valves, Pumps, and Flanges

The Facility has a complex network of pipelines, and the pipelines have process components that each result in small emissions of hydrocarbons from the seals in the process components. These process components include approximately 5,000 miles of pipe, 105,000 valves (including pressure relief devices), 1,400 pumps and compressors, and 400,000 connectors such as flanges (which are used to connect two lengths of pipe).

APPENDIX 4.0

Cumulative Projects

TABLE A4.0-1 PLANS CONSIDERED AS PART OF THE CHEVRON REFINERY MODERNIZATION PROJECT EIR CUMULATIVE IMPACT ANALYSIS

Area	Lead Agency (if applicable)	Project/Plan	Project Name	Project Location	Description	Filed/Status		Environmental Review Status
Project site	City of Richmond	Project	Sulfur Tank Replacement	Internal Refinery	Project would replace one of the two existing sulfur storage tanks in-kind (same size and location). Tank would be 70' 40' high.	Est. Construction Quarter 2015	Start: 1st End: 2nd Quarter 2015	Permit application not yet developed.
Project site	City of Richmond	Project	Sulfur Loading Rack Replacement	Internal Refinery	Replace the existing sulfur loading rack which is nearing the end of its useful life. Included are two sulfur loading pumps, a water scrubber, a caustic scrubber, caustic circulation pumps, a vent blower, and a caustic storage tank. The existing loading rack would be decommissioned and dismantled following construction of the replacement rack.	Est. Construction Quarter 2014	Start: 2nd end: 3rd Quarter 2015	Permit application submitted to BAAQMD Oct. 2013.

Source: City of Richmond, 2014. Contra Costa County, 2014.

TABLE A4.0-2 CHEVRON PROJECTS WITHIN OR NEAR THE PROJECT SITE CONSIDERED AS PART OF THE CHEVRON REFINERY MODERNIZATION PROJECT EIR CUMULATIVE IMPACT ANALYSIS

Area	Lead Agency (if applicable)	Project/Plan	Project Name	Project Location	Description	Filed/Status		Environmental Review Status
Project site	City of Richmond	Project	Sulfur Tank Replacement	Internal Refinery	Project would replace one of the two existing sulfur storage tanks in-kind (same size and location). Tank would be 70' 40' high.	Est. Construction Quarter 2015	Start: 1st End: 2nd Quarter 2015	Permit application not yet developed.
Project site	City of Richmond	Project	Sulfur Loading Rack Replacement	Internal Refinery	Replace the existing sulfur loading rack which is nearing the end of its useful life. Included are two sulfur loading pumps, a water scrubber, a caustic scrubber, caustic circulation pumps, a vent blower, and a caustic storage tank. The existing loading rack would be decommissioned and dismantled following construction of the replacement rack.	Est. Construction Quarter 2014	Start: 2nd End: 3rd Quarter 2015	Permit application submitted to BAAQMD Oct. 2013.
Project site	RWQCB	Project	Dredge Spoils to 250' Channel	Internal Refinery	Project would make repairs to the Point Orient Wharf, and construct a pipeline from that wharf across the northern tank farm through the Refinery to the 250' Channel. Includes pumps, electrical, and related infrastructure.	Est. Construction Quarter 2014	Start: 4th End: 4th Quarter 2015	Initial Study to be prepared by RWQCB
Hensley Street / Richmond Parkway	City of Richmond	Project	Hensley Street and Kelham Warehouse Redevelopment Project	Hensley St. (former Ag. Chem facility)	Project to redevelop the Hensley Street and Kelham warehouse sites for light industrial uses.	Est. Construction Quarter 2015	Start: 1st End: TBD	NOP with Initial Study expected to be released 1 st quarter 2014
Project site	City of Richmond	Project	Maintenance Shops Building	Internal Refinery	Construct a new 2-story building to consolidate maintenance shops.	Est. Construction Quarter 2015	Start: 1st End: 1st Quarter 2016	Design Review required by City of Richmond
Project site	City of Richmond	Plan	Major Refinery Turnaround	Internal Refinery	Routine shutdown of process unit(s) for scheduled maintenance.	On-going		
Project site	City of Richmond	Project	Long Wharf Maintenance and Reliability Project	Long Wharf	Maintenance and retrofits to the existing Long Wharf. This includes replacement of three (3) existing vessel access gangway towers, addition of three (3) fire water monitors, addition of three (3) mooring dolphins and hooks, addition of standoff fenders replacement of all existing loading arms, replacement of three (3) existing hose cranes, and seismic retrofit to the Berth 4 loading platform.	Est. Construction Quarter 2015	Start: 2nd End: 3rd Quarter 2017	Permit applications to be submitted 1 st quarter 2014
Project site	City of Richmond	Project	Storage Tank Replacement Project	Internal Refinery	Construct five (5) new hydrocarbon storage tanks and one (1) firewater tank.	Construction Quarter 2011	Start: 2nd End: 3rd Quarter 2015	MND adopted and CUP approved March 2011

TABLE A4.0-3 OTHER, NON-CHEVRON REFINERY AND PIPELINE PROJECTS CONSIDERED AS PART OF THE CHEVRON REFINERY MODERNIZATION PROJECT EIR CUMULATIVE IMPACT ANALYSIS

Area	Lead Agency	Project/ Plan	Project Name	Project Location	Description	Filed/Status	Environmental Review Status
City of Benicia	City of Benicia	Project	Valero Improvement Project	3400 East Second Street, Benicia	Modify existing and install new refining equipment, including new hydrogen plant.	Original Authority to Construct (ATC) issued 12/16/2008, request to extend ATC to 2014 submitted to BAAQMD in July 2012	EIR completed
City of Benicia	City of Benicia	Project	Valero Crude by Rail	3400 East Second Street, Benicia	Install a rail car unloading rack, repurpose an existing tank to include crude oil service, and construct associated infrastructure, including rail lines, to allow Valero to receive crude oil by train. Project would allow Valero to receive a larger proportion of its crude oil by railcar, up to 70,000 barrels per day of North American crude.	Land use permit application submitted 12/12	NOP 8/9/2013; Draft EIR release date is tentatively scheduled for March 2014
City of Pittsburg	City of Pittsburg	Project	WesPac Pittsburg Energy Infrastructure Project	696 West 10 th Street, Pittsburg, CA	Crude oil storage. A crude oil terminal to receive and ship crude oil by train, ship, barge, or pipeline.	Est. Construction Start: 3rd Quarter 2014 Est. Start of Operations: 4th Quarter 2015	Preparing to recirculate EIR. Comment period for last Recirculated EIR ended September 13, 2013.
Contra Costa County	Contra Costa County	Project	Phillips 66 Propane and Butane Recovery Project	1380 San Pablo Avenue in unincorporated Contra Costa County, near town of Rodeo.	Construction of Propane Recovery Plant for separating propane and additional butane from refinery fuel gas; construction of new Fuel Gas Hydrotreating Plant to lower sulfur content in refinery fuel gas; construction of ten new propane vessels and associated treatment facilities; new truck and rail infrastructure for loading increased propane and butane as product.	Planning commission approved. Application on appeal to Board of Supervisors starting in 1/2014, pending information from BAAQMD	EIR completed, but not certified by Board of Supervisors.
Contra Costa County	Contra Costa County	Project	New Shell Crude Oil Tank construction	Contra Costa County	The proposed Project will result in an increase of crude oil storage capacity at the facility by approximately 800 thousand barrels (MBbl). Increase in the volume of crude oil shipments received at the marine terminal (approximately one additional ship per week) to maintain production levels as crude oil delivered by vessel replaces San Joaquin Valley crude oil received by pipeline. Implement emission reduction projects as proposed measures to reduce project emissions to, or below, CEQA thresholds.	Application was approved November 2011. Construction expected to be complete late 2014.	EIR certified 11/12
Contra Costa County	Contra Costa County	Project	Shell Green House Gas Reduction project	Contra Costa County	Doing modifications on existing processing equipment and shutting down a coker.	Application submitted 1/2014. Construction starting in 2015	Starting CEQA process
Contra Costa County	Contra Costa County	Project	Praxair 21.5 Mile Hydrogen Pipeline Project	Multi-jurisdictional (Pinole, Hercules, Martinez, Richmond, Unincorporated County)	21.5-miles of hydrogen pipeline from the Chevron refinery in Richmond to the Shell refinery in Martinez, with a lateral line connecting to the ConocoPhillips refinery in Rodeo. The project will also involve the construction of approximately 2.1-miles of 16-inch natural gas line from an existing PG&E line to the Chevron Refinery, which will run adjacent to a segment of the proposed hydrogen line.	On hold.	Draft EIR completed
City of Richmond	City of Richmond	Project	International-Matex Tank Terminals (IMTT) Richmond Wharf Seismic Upgrades	100 Cutting Boulevard, Richmond, CA	Existing wharf will be upgraded to comply with Marine Oil Terminal Engineering and Maintenance Standards by replacing the existing timber wharf and pilings and replacing these portions of the timber structure with three loading platforms supported by steel piles, eight steel monopole dolphins, associated access ramps and catwalks, and new marine transfer manifolds, all within the existing wharf footprint.	Under construction	Categorical Exemption filed Aug. 2013
City of Martinez	State of California	Project	Tesoro Amorco Marine Wharf Terminal Lease Consideration	Martinez, CA	The proposed project includes an application for a new 30-year lease of sovereign lands to Tesoro for the Amorco Terminal, which would allow Tesoro to continue to operate its Amorco Terminal through 2043. This project would result in maintaining the level of crude oil feedstock imported through the existing Amorco Terminal.	Approved February 21 2014	Final EIR certified February 21, 2014
City of Martinez	State of California	Project	Tesoro Avon Marine Wharf Terminal Lease Consideration	Martinez, CA	The proposed project includes approval of a new 30-year lease to Tesoro to continue current operations of the Avon Marine Oil Terminal, and includes upgrades on the Avon Terminal to meet Marine Oil Terminal Engineering Maintenance Standards (including decommissioning of Berth 1; construction of a new berthing area; repairs, retrofits, and construction on the existing approach trestle; and demolition and removal of existing Berth 5).		Notice of Preparation published April 2, 2014

TABLE A4.0-4 OTHER PROJECTS IN THE CITY OF RICHMOND CONSIDERED AS PART OF THE MODERNIZATION PROJECT EIR CUMULATIVE IMPACT ANALYSIS

Area	Lead Agency	Project/ Plan	Project Name	Project Location	Description	Filed/Status	Environmental Review Status
City of Richmond	City of Richmond	Project	Parkway Commerce Center	Giant Hwy/Richmond Pkwy	11 lots-industrial use	Approved in 2005.	MND adopted
City of Richmond	City of Richmond	Project	Point Molate Project	Waterfront north of Richmond/San Rafael bridge.	Alternative D: Hotel Conference Center, Residential and Commercial Development, Parkland, Ferry Terminal	No significant historical connection found for Guidiville Tribe 9/2/2011	FEIR Certified
City of Richmond	Caltrans	Project	I-580 Scofield Avenue and Western Drive Bridge Deck	Western Drive	Caltrans project east of Richmond-San Rafael Bridge toll plaza to replace concrete decks for three under crossings	In contract award phase	(CE/CE) determination was issued on 3-16-2009
City of Richmond	City of Richmond	Project	Elevated Bay Trail	Castro Street to Richmond-San Rafael Bridge	Elevated, multi-use, ADA accessible trail	Caltrans approval process and final design in 2013	Under review
City of Richmond	City of Richmond	Project	Filbert Townhomes	Fred Jackson Way (formerly Filbert Street)	43 low/mod townhomes	Estimated Completion in 2014	Categorical Exemption
City of Richmond	City of Richmond	Project	Nevin Court	Nevin and First	20-30 low/mod rental units	Estimated Completion in 2014	Under Review
City of Richmond	City of Richmond	Project	Metro Walk Transit Village	West Macdonald	Transit-oriented mixed-use with housing, retail and parking garage	Phase I: Complete- 132 housing units Phase II: 10,750 sq.ft. of retail complete, garage for BART station complete, 99 housing units not yet constructed	MND adopted
City of Richmond	Richmond Housing Authority	Project	Nystrom Village	222 Marina Way South	Phase I: Rehabilitation of 48 units (24 duplex buildings) and 1 management office.	Phase I Date of Completion June 2015	Categorical Exemption
City of Richmond	City of Richmond	Project	Richmond Wet Weather Storage Project	601 Canal Boulevard	Construction of a new diversion box, pump station, pipeline, and an above ground, circular, pre-stressed concrete tank with storage volume of approximately 5 million gallons (MG). The tank will be approximately 150 feet in diameter and approximately 53 feet tall. Water Pollution Control Plant effluent will be used to supply water to the wash down system used to clean the tank. The tank will be covered to contain odors.	Under review by City	Final MND issued December 2013
City of Richmond	City of Richmond	Project	Westshore Marina	Marina Way South	300 residential condos	4/2006 Approved	FEIR 2005
City of Richmond	City of Richmond	Project	Terminal One/Point Richmond Shores	Point Richmond Waterfront/Dornan Drive	258 residential units	Approved 2006; City seeking new developers.	FEIR Completed
City of Richmond	City of Richmond	Project	Shea Homes Bottoms Property	Seacliff Drive	60 Residential Units on 25.27 Acres, 15.1 acres submerged in water. Units developed on 6.23 acres.	Under review by City	NOP issued October 2013
City of Richmond	Water Emergency Transportation Authority	Project	Ferry Terminal	Ford Peninsula, adjacent to Ford Building along an existing wharf	Floating gangway and dock adjacent to Craneway. No new buildings. Generally replacing existing facility. Parking for 266 vehicles.	MNd Scoping Session on June 21, 2012 11/15/2012	IS/MND anticipated to be released 3 rd Quarter 2014
City of Richmond	City of Richmond	Project	Marina Way Live /Work	900 Marina Way South	64 industrial live/work	Approved in 2005 –Phase 1 under construction	MND adopted October 2007
City of Richmond	City of Richmond	Transportation Project	"Moody Underpass" Marina Bay Parkway Grade Separation	845 Marina Bay Parkway	Construction of a roadway undercrossing at the intersection of Marina Bay Parkway and Burlington Northern Santa Fe/Richmond Pacific Railroad Corporation railroad tracks	Approved 4/11/2012 Under construction	CEQA Exemption Filed

TABLE A4.0-4 OTHER PROJECTS IN THE CITY OF RICHMOND CONSIDERED AS PART OF THE MODERNIZATION PROJECT EIR CUMULATIVE IMPACT ANALYSIS

Area	Lead Agency	Project/ Plan	Project Name	Project Location	Description	Filed/Status	Environmental Review Status
City of Richmond	City of Richmond	Project	University of California, Berkeley and Lawrence Berkeley National Laboratory (UCB LBNL) Richmond Bay Campus	Richmond Field Station: 1301 South 46th Street	University of California, Berkeley “Richmond Bay Campus” consolidates biosciences activities managed by Lawrence Berkeley National Laboratory. 134 acres with 5.4 million square feet over 40 years starting in 2017-2020. Estimated daily population of 10,000	Draft EIR released for public comment NOP filed January 4, 2013	Draft EIR completed
City of Richmond	City of Richmond	Project	Miraflores Housing Development	Bound 45th St. and Wall Ave, I-80 and BART	110 affordable rental units for seniors; 226 market-rate detached/attached single-family units.	Approved 12/09. Agreements with for-profit and non-profit developers proceeding. Est. completion 2014 (according to CHDC July 2011).	FEIR certified on 12/14/2009

APPENDIX 4.3

Air Quality

APPENDIX 4.3 -CHRA

CHRA: Air Dispersion Modeling and Health Risk
Assessment Methodologies for Construction

APPENDIX 4.3

CHRA: AIR DISPERSION MODELING AND HEALTH RISK ASSESSMENT METHODOLOGIES FOR CONSTRUCTION

This document describes the methods and results of a health risk assessment (HRA) that evaluates potential public health effects from toxic air contaminant (TAC) emissions generated by the construction associated with the Modernization Project. TACs are compounds designated by the California's Environmental Protection Agency (Cal/EPA) Office of Health Hazard Assessment (OEHHA) as known or suspected to cause adverse health effects after short-term (acute) or long-term (chronic) exposure. In addition to naming certain chemicals as TACs, the OEHHA also provides information that allows the prediction of health impacts associated with the public's potential exposure to TACs. This information is used in an HRA to estimate the potential public health impacts resulting from TAC emissions from construction associated with the Modernization Project.

In addition to evaluating TACs, this HRA also predicts the ambient air concentrations of fine particulates—i.e., particulate matter less than 2.5 microns in diameter ($PM_{2.5}$)—to evaluate consistency with Bay Area Air Quality Management District (BAAQMD) California Environmental Quality Act (CEQA) thresholds for $PM_{2.5}$.

Concentrations in the air are calculated from TAC emissions using air dispersion modeling. Air dispersion modeling is the mathematical estimation of pollutant impacts from emissions sources within a study area. Information on factors that impact the fate and transport of pollutants in the atmosphere including: meteorological conditions, site configuration, emission release characteristics, and surrounding terrain, are used in the dispersion model. Once concentrations are calculated using air dispersion modeling, the risks are calculated using information on how much air people breathe and the toxicity of the chemical considered. The resulting cancer risks and chronic and acute hazard index (HI), as described above, are compared to the BAAQMD CEQA thresholds to assess significance.

The incremental carcinogenic and non-carcinogenic inhalation health risks from the Modernization Project construction were determined through dispersion modeling of the emissions from the construction associated with the Modernization Project TAC emissions and applying OEHHA toxicity factors to the predicted TAC concentrations consistent with the BAAQMD (2010a) and OEHHA Hot Spots Guidance (OEHHA, 2003).

This HRA was prepared in accordance with the Recommended Methods for Screening and Modeling Local Risks and Hazards (BAAQMD, 2012). In general, the Protocol follows the methodology for preparing Tier 1 risk assessments described in The Air Toxics Hot Spots Program Guidance Manual for Preparation of Health Risk Assessments (OEHHA, 2003). Prior to development of the HRA, the general approach and project-specific decisions were discussed with and reviewed by the BAAQMD prior to implementation.

1.1 OVERVIEW OF HEALTH RISK ASSESSMENT

Health risk assessments are used to estimate whether current or future chemical exposures will pose health risks to a broad population, such as a city or a community. Scientific methods used in health risk assessment cannot be used to link individual illnesses to past chemical exposures, nor can health risk assessments and epidemiologic studies prove that a specific toxic substance caused an individual's illness. In general, three types of health impacts are evaluated: cancer risk, chronic (long-term) health impacts, and acute (short-term) health impacts.

In order to evaluate the health impact of a chemical in the ambient air, some evaluation of toxicity must be determined. Consistent with OEHHA guidance, all chemicals that are emitted from the construction of the Modernization Project, and have toxicity values, were evaluated. This list is contained in Table A4.3-CHRA-1.

Individuals can be exposed to chemicals that are emitted into the air several different ways. They can breathe the air, and the chemicals in the air may remain in their lungs or may be absorbed into their bloodstream via the lungs. Chemicals in the air can be deposited on the ground and may come into contact through the skin (this is known as "dermal exposure") because an individual may touch the chemical that has deposited to the ground. The chemical may come into contact with food that an individual eats or may be ingested because it gets on the fingers of an individual. This is known as "oral exposure." Finally, infants can come into chemicals that may contaminate its mother's milk. OEHHA has designated which chemicals may result in risks from dermal, oral, and mothers' milk pathways. Only certain chemicals are recognized by OEHHA to have potential impacts by the oral, dermal or mother's milk routes. These chemicals are specified in the OEHHA Air Toxics Hot Spots Program Risk Assessment Guidelines: Technical Support Document for Exposure Assessment and Stochastic Analysis, Appendix E (Cal/EPA, 2012).

OEHHA Hot Spots Guidance (OEHHA, 2003; Cal/EPA, 2012) requires the evaluation of non-inhalation exposure pathways, referred to as a multi-pathway

analysis, in risk assessments prepared to meet the 2010 BAAQMD CEQA Guidelines. Selection of the additional pathways for a multi-pathway analysis is specific to the chemical and land use designations in the area impacted by the facility.

Multi-pathway factors, which represent the mathematical combination of the toxicity values and exposure parameters specific to this HRA, can be generated to estimate health risks for the multi-pathway exposures by combining with the air modeling results. Because risks from construction are primarily related to diesel particulate matter (DPM) and there is no multipath evaluation recommended for DPM, no multipath risks were evaluated for this analysis.

The HRA process requires the completion of four general steps to estimate health impact results: (1) quantify project-generated TAC emissions; (2) identify ground-level receptor locations that may be affected by the emissions (including both a regular grid of receptors and any additional sensitive receptor locations such as schools, hospitals, convalescent homes, and/or daycare centers); (3) perform dispersion modeling analyses to estimate ambient TAC concentrations at each receptor location; and (4) use established methods to estimate potential health effects at each receptor location.

The first step in an HRA is to identify the TACs that are being emitted from a source, and quantifying the amount of chemicals emitted from each location. For future sources of emissions like those associated with the construction of the Modernization Project, engineers use information about similar sources to estimate emissions, and locations of emissions. Once the identity and location of the sources of TAC emissions are known, the next step is to determine how it moves away from the sources into the ambient air.

Engineers use computer models to estimate the amount of pollutant at different distances from the source. Computer models use mathematical equations that represent the processes that occur when a facility releases a pollutant and also the movement of pollutants through the air. Factors such as distance from the source to exposed persons, wind speed and direction, and smokestack height affect these estimates.

The final step in an air pathway exposure assessment is to estimate the amounts each person inhales. To do this, scientists combine estimates of breathing rates and lifespan of an average person with estimates of the amount of pollutant in the air that person breathes. The exposure assessment also considers how much pollutant may reach the individual through contact with the skin or through ingestion.

Toxic air pollutants can cause health problems by interfering with normal body functions. Most commonly they change chemical reactions within individual cells, the building blocks of living things. These changes can kill cells, impair cell function, or re-direct cell activity. The results can be damaged organs, birth defects when the cells of an unborn child are damaged, or cancer that develops when cells begin to grow at an uncontrolled rate.

The dose-response relationship for a specific pollutant describes the association between exposure and the observed response (health effect). In other words, it estimates how different levels of exposure to a pollutant change the likelihood and severity of health effects. Scientists use results of animal and human studies to establish dose-response relationships.

In the absence of clear evidence to the contrary, the United States Environmental Protection Agency (EPA) and OEHHA assume that there are no exposures that have “zero risk”—even a very low exposure to a cancer-causing pollutant can increase the risk of cancer (albeit a small amount). The EPA and OEHHA also assume that the relationship between dose and response is a straight line—for each unit of increase in exposure (dose), there is an increase in cancer response.

For non-cancer causing chemicals, a dose may exist below the minimum health effect level for which no adverse effects occur. The EPA and OEHHA typically assume that at low doses the body’s natural protective mechanisms repair any damage caused by the pollutant, so there is no ill effect at low doses. However, for some substances, noncancer effects may occur at low doses. The dose-response relationship (the response occurring with increasing dose) varies with pollutant, individual sensitivity, and type of health effect.

Risk assessment results are presented as calculated cancer risks and non-cancer hazards during the risk characterization step. Cancer risk estimates represent the probability of cancer (presented as a probability per million people) related to potential exposures to pollutants evaluated in the HRA. Non-cancer hazards are represented as the ratio between the estimated dose (i.e., intake of chemical) and chemical-specific reference exposure level developed and approved by Cal/EPA for a specific health endpoint (e.g., eye or lung irritation). The cancer risk or non-cancer hazard index estimate is then compared to a threshold level that is intended to be protective of public health. This comparison aids the Lead Agency in prescribing appropriate actions to mitigate risks, if needed. If cancer risk estimates exceed the significance level, then all feasible mitigation must be applied to the project.

1.1.1 Quantification of Project Construction TAC Emissions

The major sources of emissions of TACs from Modernization construction is in the exhaust of heavy equipment operating at the Facility and vehicles used to transport materials and people to and from the Facility.

The quantification of TAC emissions generated by construction of the Modernization Project is described in *Appendix 4.3-CST*.¹ The methodology is also briefly described here.

1.1.1.1 Construction TAC Emissions

The estimation of emissions from construction of the Modernization Project is more fully described in *Appendix 4.3-CST*, and briefly summarized here. Construction emissions were estimated for all phases of construction, including: hydrogen plant replacement, existing hydrogen plant dismantling, sulfur removal improvements, project design features (existing storage tank domed roof installation, project water reuse, and light-emitting diode [LED] lighting) (Chevron Data Transmittal #47A (Rev #6), 2014),² and related piping and other ancillary equipment (hydrogen plant tie-in). These construction phases involve emission-generating sources such as off-road construction equipment, delivery trucks, flatbed trucks, haul trucks, worker commuting vehicles, worker transport vehicles, paving and coating activities, and fugitive dust.

There are four general types of construction criteria air pollutant (CAP) sources:

- off-road construction equipment;
- on-road mobile sources;
- architectural coatings and paving;
- fugitive dust sources;
- Only the on-road sources and off-road construction emissions generate TACs that are considered in the construction HRA.

The California Air Resources Board (CARB) 2011 In-use Off-road Equipment Inventory Model (OFF-ROAD 2011), and Emission FACtor Model (EMFAC2011), together with construction schedule and activity data provided by Chevron were

¹ See Tables 4.3-CST-16, 17, 19, and 21 for construction TAC emissions.

² Construction associated with LED lighting is expected to be negligible. Also the emissions associated with the Fluidized Catalytic Cracker Cooling Water Tower Motor Upgrade was not quantified due to the short duration of the activity (Chevron Data Transmittal #360 (Rev #3), 2014).

used to calculate emissions. When site-specific data was not available, default assumptions consistent with CalEEMod™ were used. This methodology is consistent with CalEEMod™ and is capable of incorporating the detailed activity data Chevron provided.

Only TAC emissions used in the HRA were estimated. Because of this, while the physical domain for the TAC emissions inventory includes all on-site construction TAC sources, the physical extent of off-site TAC emissions included for the HRA is smaller than the extent of off-site emissions included for the criteria pollutant inventory. The number of Modernization Project-related construction trucks and worker commuting vehicles on highways is very small relative to highway background traffic; because of this, their emissions will not have a significant health impact on the sensitive population located along the highways. Accordingly, receptors that are exposed only due to their proximity to a highway that may be used by trucks going to and from the Chevron construction sites were not included in the HRA, and thus the portion of emissions from worker commuting vehicles and construction trucks that occurs on the highways were also not included in the TAC inventory used in the HRA. The TAC inventory does include Modernization Project-related truck and worker commuting emissions associated with travel along Richmond Parkway, Castro Street, and on the highway on- and off-ramps.

The TAC emissions inventory includes chemicals emitted from sources that are included for consideration in HRAs consistent with BAAQMD Regulation 2, Rule 5. The TAC emissions inventory for construction is based on DPM emissions from the off-road construction equipment and the diesel on-road vehicles, and gasoline total organic gases (TOGs) from the gasoline on-road vehicles. $PM_{2.5}$ concentrations were also calculated as part of the health risk assessment for comparison to BAAQMD CEQA Thresholds for ambient concentrations of $PM_{2.5}$.

Diesel exhaust, a complex mixture that includes hundreds of individual constituents (CARB, 1998), is identified by the State of California as a known carcinogen (CARB, 2014). Under California regulatory guidelines, DPM is used as a surrogate measure of carcinogen exposure for the mixture of chemicals that make up diesel exhaust as a whole. Cal/EPA and other proponents of using the surrogate approach to quantifying cancer risks associated with the diesel mixture indicate that this method is preferred over the use of a component-based approach. A component-based approach involves estimating risks for each of the individual components of a mixture. Critics of the component-based approach believe it will underestimate the risks associated with diesel as a whole mixture because the identity of all chemicals in the mixture may not be known and/or exposure and health effects information for all chemicals identified within the mixture may not be available. Furthermore, Cal/EPA has concluded

that “potential cancer risk from inhalation exposure to whole diesel exhaust will outweigh the multi-pathway cancer risk from the speciated components” (OEHHA, 2003). The respirable particulate (particulate matter less than 10 microns in diameter) emissions from the off-road construction equipment and the diesel on-road vehicles were assumed to be equivalent to DPM in the emissions estimation.

TACs from exhaust and evaporative TOGs emissions from gasoline-fueled vehicles were evaluated based on the speciation profiles presented in the BAAQMD guidelines, which include: acetaldehyde, acrolein, benzene, 1,3-butadiene, ethylbenzene, formaldehyde, hexane, methanol, methyl ethyl ketone, naphthalene, propylene, styrene, toluene, and xylenes (BAAQMD, 2012).

The construction TACs and PM_{2.5} emissions inventory is contained in Tables 4.3-CST-16, 17, 19, and 21. The emissions by source group are presented in Tables A4.3-CHRA-2a, 2b, and 2c.

1.2 ESTIMATING AIR CONCENTRATIONS USING AIR DISPERSION MODELING

In order to estimate risks, ambient air concentrations resulting from the Modernization Project must be evaluated. This is done by simulating the dispersion of emissions into the air using a mathematical simulation, called air dispersion modeling. Details on the methodologies used to estimate TAC and PM_{2.5} concentrations in the ambient air to be used in the Modernization Project health risk assessment are discussed below.

1.2.1 Model Selection and Options

The regulatory default mode of the EPA’s state-of-the-art regulatory air dispersion model AERMOD (version 12345)³ was used to estimate TAC and PM_{2.5} concentrations at all receptor locations. AERMOD is appropriate for use in estimating ground-level ambient air concentrations resulting from non-reactive buoyant emissions from sources located in simple or complex terrain. This analysis was conducted using AERMOD in the regulatory default mode, which includes the following modeling control options:

³ On November 9, 2005, the EPA promulgated final revisions to the federal Guideline on Air Quality Models, in which they recommended that AERMOD be used for dispersion modeling evaluations of criteria air pollutant and toxic air pollutant emissions from typical industrial facilities. The model can be downloaded at: http://www.epa.gov/scram001/dispersion_prefrec.htm.

- adjusting stack heights for stack-tip downwash;
- using upper-bound concentration estimates for sources influenced by building downwash;
- incorporating the effects of elevated terrain;
- employing the calms processing routine;
- employing the missing data processing routine.

Air dispersion models such as AERMOD require a variety of inputs such as source parameters (including emission rates), meteorological parameters, topographic information, and receptor parameters.

1.2.2 Modeled Receptor Locations

Receptor locations specify where the model will provide air concentration estimates. Consistent with the BAAQMD's recommendations (BAAQMD, 2012), this analysis estimated TAC concentrations at potential sensitive receptor locations including "people—children, adults, and seniors—occupying or residing in:

- Residential dwellings, including apartments, houses, condominiums;
- Schools, colleges, and universities;
- Daycares;
- Hospitals; and
- Senior-care facilities."

BAAQMD CEQA Guidance (BAAQMD, 2012) requires sensitive receptors within Modernization Project "radius of impact," which is typically 1,000 feet surrounding the Facility boundary to be evaluated. Moreover, the Guidance indicates that locations where "people reside for long periods should [also] be considered sensitive, residential receptors," and should be included in the CEQA analysis. Because of the size and nature of the Modernization Project, the receptors included in this analysis extend beyond the radius of impact and beyond the definition of sensitive receptors indicated in the Guidance. Modeling input files, which include a complete list of the receptors are provided in Attachment 1 and shown in Figure A4.3-CHRA-1, and details on modeled receptors are provided below.

1.2.2.1 Coarse Receptor Grid

As shown in Figure A4.3-CHRA-1, receptors were modeled at each point defined by a receptor grid with 200 meter by 200 meter spacing ("coarse grid"), on a 12-by 12-kilometer modeling domain. The type of receptor (e.g., residential or

worker) evaluated at each location in the coarse grid was assigned based on land use.

1.2.2.2 Residents

Concentrations at points in a “fine grid” of receptors spaced 50 meter apart were modeled over several residential areas in the vicinity of the Facility. The residential communities covered by the fine grids include Point Richmond, Atchison Village, Santa Fe, Iron Triangle, Shields-Reid, central and downtown Richmond, and North Richmond. In addition, potential residential receptors at the Point San Pablo Yacht Harbor are covered by the fine grid. Other residential communities further away from the Facility that are covered or partially covered by the coarse grid include Tara Hills, Parchester Village, El Sobrante, San Pablo, East Richmond, Pinole, El Cerrito, and Albany.

1.2.2.3 Other Sensitive Receptors

Concentrations were also estimated at specific receptor locations to represent surrounding sensitive populations. Sensitive receptors evaluated for this Modernization Project include schools, health care facilities, and care centers for children or the elderly.⁴ Sensitive receptor locations within the 94801 and 94804 zip code areas (in the cities of Richmond, Point Richmond, and San Pablo) were identified from searches of the following sources:

- Schools (public and private) – California Department of Education, California School Directory (CDE, 2013)
- Health Care Facilities – California Office of Statewide Health Planning and Development (OSHPD, 2014)
- Childcare and Elderly Care Centers – California Department of Social Services, Community Care Licensing Division (CCLD, 2012)
- Google Map (<https://www.maps.google.com/>, using keyword of “childcare,” “daycare,” and “school” to supplement the searches above)

All the identified addresses within 1 mile of the Facility boundary were then geocoded and mapped in the geographic information system. Quality assurance was performed on all geocoded addresses to confirm that mapped locations

⁴ Residential units and worker receptors were identified using Google Map. List of city parks and community centers was provided to ENVIRON by the City of Richmond. Other sensitive receptor locations were obtained from searching various California government licensing departments, supplemented by Google search.

appear to be the correct facility. The sensitive receptors that were included in the HRA are shown in Table A4.3-CHRA-3.

1.2.2.4 Additional Receptors

Other receptors that do not fall under BAAQMD's definition of sensitive receptors were also included in the risk assessment. Worker receptors at points spaced 50 meters apart in a "fine grid" were modeled over several industrial and office areas in the vicinity of the Facility. The industrial areas covered by the fine grid are the on-site San Rafael Rock Quarry close to the southwest corner of the Facility, and the General Chemical Plant, just outside of the east Facility boundary, across Castro Street from the BNSF Richmond Rail Yard. The office park just outside of southeast corner of the Facility boundary, on the north side of the Chevron Way is also covered by the fine grid.

Furthermore, recreational receptors at off-site recreational facilities (i.e., parks) as well as a series of boundary receptors outlining the Facility boundary were included in the model. The boundary receptors were used to estimate acute non-cancer impacts only, which are independent of receptor type.

1.2.2.5 Receptor Modeling Parameter Specifications

In accordance with BAAQMD guidance, a default breathing height of 1.8 meters was used for all receptors. Figure A4.3-CHRA-1 presents modeled receptors.

1.2.3 Physical Domain for Health Risk Analysis

The physical scope of the health risk analysis includes sources within the Project site boundary ("on-site sources"). However, only the subset of Modernization Project off-site TAC sources that would impact receptors in the vicinity of the Modernization Project was included in the risk analysis. Thus, the physical extent of off-site emissions included in the TAC inventory for the HRA analysis is smaller than the extent included for the criteria pollutant inventory, as the criteria pollutant inventory extends to the BAAQMD boundary.

Off-site emissions consist of on-road emissions from construction worker commuting vehicles, construction haul trucks and delivery trucks. The emission estimates from these off-site activities for the TAC inventory included emissions associated with travel of these mobile sources along the off-site segments on Richmond Parkway, Castro Street, and the highway ramps taken by the vehicles to get on or off the highways. Emissions associated with travel on the highways were not included in the risk analysis, as the number of Modernization Project-related construction haul trucks and delivery trucks, and construction worker commuting vehicles on highways is very small relative to highway background

Figure A4.3-CHRA-1
Chevron Refinery Modernization Project EIR
Modeled Receptor Locations

traffic, and therefore, their emissions will not have a significant health impact on the residential and sensitive population along the highways.

1.2.4 Source Types, Locations, and Parameters

1.2.4.1 Construction

The construction areas for the Modernization Project are located in the center, north, and south areas of the Project site. The general construction areas are presented in Figure A4.3-CHRA-2 and Figure A4.3-CHRA-3. Construction will occur in eight construction areas, indicated in Figure A4.3-CHRA-2 and Figure A4.3-CHRA-3 as new hydrogen plant, existing hydrogen plant, sulfur recovery unit, fluid catalytic cracker feed hydrotreater (FCC FHT), hydrogen plant tie-in, water reuse (two areas), and existing storage tank doomed roof installation (Chevron Data Transmittal #47A (Rev #6), 2014).⁵ Some completed construction activities involving off-road equipment occurred in 2008-2009 within the new hydrogen plant, sulfur recovery unit, FCC FHT and hydrogen plant tie-in areas. Off-road equipment is expected to operate in all eight construction areas for future construction.

In addition, on-road vehicle trips associated with the construction occur both within and outside the Facility boundary. Figures A4.3-CHRA-4 to A4.3-CHRA-7 show the construction worker and truck (delivery truck, flatbed and haul truck) routes. In general, construction haul trucks travel from Interstate 580 (I-580) or Interstate 80 (I-80) to the Facility via Castro Street or Richmond Parkway. Then, construction haul trucks enter the Facility through Gate 31 and travel north to the new hydrogen plant, sulfur recovery unit, FCC FHT, and hydrogen plant tie-in area where soil excavation occurs or clean fill is imported. Construction haul trucks leave the Facility and travel back to the highways using the same routes. According to Chevron, 80% of the construction haul trucks use highway I-80 via Richmond Parkway to arrive at and depart from the Facility, while the remaining 20% use highway I-580 via Castro Street (Chevron Data Transmittal #360 (Rev #3), 2014).

Similarly, construction delivery trucks travel from highways I-580 or I-80 to the Facility via Castro Street or Richmond Parkway. Then, construction delivery trucks enter the Facility through Gate 31 and travel and travel north then south to

⁵ Construction associated with LED lighting is expected to be negligible. Also the emissions associated with the FCC Cooling Water Tower Motor Upgrade was not quantified due to the short duration of the activity (Chevron Data Transmittal #360 (Rev #3), 2014).

Facility laydown area and unload materials and equipment.⁶ Then, the on-site delivery trucks and flatbeds pick up these materials and equipment, and delivery them to the eight construction areas mentioned above. Construction delivery trucks leave the Facility laydown area and travel back to the highways using the same routes. According to Chevron, 80% of the construction delivery trucks use highway I-80 via Richmond Parkway to arrive at and depart from the Facility, while the remaining 20% use highway I-580 via Castro Street (Chevron Data Transmittal #36O (Rev #3), 2014).

Construction worker commuting vehicles also travel from highways I-580 or I-80 to Facility Gate 91 via Castro Street or Richmond Parkway; however, they will park in a worker parking lot north of Facility Gate 91. Then, workers will be transported to the eight construction areas described above by Facility vehicles including buses, pickups, and cars (collectively called worker transport vehicles in Appendix 4.3-CST and this Appendix 4.3-CHRA). Construction workers leave the Facility and travel back to the highways using the same routes; 50% of the worker commuting trips use highway I-80 via Richmond Parkway, while the other 50% use Highway I-580 via Castro Street (Chevron Data Transmittal #36O (Rev #3), 2014).

Construction emission sources included in the air toxics dispersion model include off-road construction equipment, diesel- and gasoline-fueled on-road vehicles such as construction trucks and worker commuting vehicles. The lists below describe how each Modernization Project source was represented as either a volume or area source in the air dispersion model.

- On-site sources
 - Off-road Construction Equipment – Volume Sources
 - On-road Vehicles (Running and Startup Emissions) – Volume Sources along travel routes
 - On-road Vehicles (Idling Emissions) – Area Sources at discrete locations
- Off-site sources
 - On-road Vehicles (Running Emissions) – Volume Sources

Each source type is discussed in detail below.

⁶ Modeled travel path for the delivery trucks between facility boundary and the laydown area is different from the actual path. In addition, the modeled path is slightly shorter than the actual path. Therefore the TAC emissions were slightly underestimated due to this discrepancy. However, the modeled travel path is much closer to the maximally exposed individual sensitive receptor location than the actual path. Therefore, the impact of this discrepancy is minimal.

1.2.4.1.1 On-Site Sources

1.2.4.1.1.1 Off-Road Equipment

During Modernization Project construction, there may be multiple pieces of diesel off-road equipment operating at different locations within a construction zone at any given time; because of this, emissions were modeled assuming equal distribution of emissions across the construction zone. The eight construction zones were each modeled as series of adjacent volume sources with the sizes and locations shown in Figures A4.3-CHRA-8 and A4.3-CHRA-9. A release height of 5 meters was used, with an initial vertical dimension of 1.4 meters and an initial lateral dimension calculated by dividing the width of the volume source by 4.3.⁷ The widths of the volume sources were 10 meters for the construction Tie-in zone, and 20 meters for the other seven construction zones, based on the recommendation of the South Coast Air Quality Management District Localized Significant Thresholds Methodology.⁸ Emissions were distributed uniformly amongst all volume sources within a given construction zone. Details of the source parameters used are presented in Table A4.3-CHRA-4.

1.2.4.1.1.2 On-Road Vehicles-Running Emissions

On-road vehicle movement was modeled using a set of consecutive volume sources. The sizing of volume sources varies between road segments such that volume sources visually fit the widths of the roads. All volumes were spaced 50 meters apart. The size and location of the sources are shown in Figures A4.3-CHRA-10a to A4.3-CHRA-24b.⁹ Release heights were 4.57 m for construction delivery trucks, flatbeds, and haul trucks, consistent with BAAQMD recommendations for Health Risk Assessments & Land Use (BAAQMD, 2010b). Release heights were 0.6 m for all other construction-related on-road vehicles including cars, pickups, buses, and worker commuting vehicles.¹⁰ The initial vertical dimensions are calculated based on the release height following EPA

⁷ This choice of modeling parameters was made in accordance with guidance provided in Localized Significance Threshold Methodology (SCAQMD, 2008) because the BAAQMD has no similar guidance for Bay Area projects.

⁸ According to the Localized Significance Threshold Methodology, dimension of the volume source was determined based on the size of the construction zone.

⁹ In general, the figures with names ended with an “a” shows the vehicle travel paths and source groups; the figures with names ended with a “b” or a “c” shows the actual modeled volume sources. These volume sources are shown as small squares in the figures. The size of the squares represents the width of the roadway segment while the spacing between the squares represents the spacing between the volume sources.

¹⁰ Consistent with CARB approved methodology (Yuan, 2006), release height of the modeled volume sources representing non-truck on-road vehicles was set to 0.6 meter.

guidance for an elevated source not on or adjacent to a building (EPA, 1995).¹¹ Initial lateral dimensions are also calculated based on volume size divided by 4.3 following EPA guidance for a single volume source (EPA, 1995).¹² Details of the source parameters used are presented in Table A4.3-CHRA-5.

1.2.4.1.1.3 On-Road Vehicles-Idling Emissions

Area sources were used to represent the haul truck, delivery truck, and flatbeds idling areas on the Modernization Project site. As described above, the idling areas are at the Facility gates (i.e., Gate 31), the Facility laydown area, and the designated laydown areas for each construction zone. The size and location of the sources are shown in Figures A4.3-CHRA-16a, 16b, 17a, 17b, 17c, 18a, 18b, 18c, and 23. The release height and initial vertical dimensions are consistent with that used for the construction haul truck movement sources described above. Details of the source parameters used are presented in Table A4.3-CHRA-5.

1.2.4.1.2 Off-Site Sources

1.2.4.1.2.1 On-Road Vehicles-Running Emissions

The source parameters for running emissions from construction-related off-site on-road vehicles are identical to the parameters used for on-site, on-road vehicles. Details of the source parameters used are presented in Table A4.3-CHRA-5.

Construction emissions allocated among source groups for TACs and $PM_{2.5}$ are included in Tables 4.3-CHRA 2a, 2b, and 2c.

1.2.5 Temporal Variation in Emission Rates

To reflect the meteorological conditions (which vary throughout the day) when construction activity is likely to occur, emitting activities from all construction sources were modeled between 6:00 a.m. and 5:00 p.m. Construction emissions were assumed to be emitted continuously during this 11-hour period; however, the intensity of construction activities (and hence emissions) was not assumed to be constant during this period, due to the staggering of worker shifts. According to Chevron, half of the construction workers arrive at 6:00 a.m. for a 10-hour shift ending at 4:00 p.m., and the other half arrive at 7:00 a.m. for a shift ending at 5:00 p.m. Therefore, the intensity of emitting activities between 6:00–7:00 a.m. and 4:00–5:00 p.m. were assumed to be 50% of the activity intensity during

¹¹ Initial vertical dimension of elevated volume sources not on or adjacent to a building is release height divided by 4.3.

¹² Initial lateral dimension of single volume sources is length of side divided by 4.3.

the 7:00 a.m.–4:00 p.m. period. The same temporal profile described above was applied for the off-road equipment and on-road vehicles that operate less than 10 hours a day, because it was not possible to determine when the equipment and vehicles would operate.

1.2.6 Meteorological Data

AERMOD requires a meteorological input file to characterize the transport and dispersion of pollutants in the atmosphere. In order to create this input file, surface and upper air meteorological data inputs, along with surface parameter data describing the land use and surface characteristics near the Facility, are first processed using AERMET, the meteorological preprocessor to AERMOD. The output file generated by AERMET is the meteorological input file required by AERMOD. Details of AERMET and AERMOD meteorological data needs are described in EPA guidance documents (EPA, 2012a; EPA, 2012b). Details of the methodology used for the meteorological data processing for the Modernization Project as well as inputs and outputs of the AERMET runs for both stations can be found in Attachment 2 of *Appendix 4.3-HRA*.

Two surface meteorological stations were found in the vicinity of the Facility: one station is maintained by Chevron and is located just south of the western end of the W. Gertrude Avenue (“Gertrude station”). The other station is a National Climate Data Center station (AWS ID 994036), located on the Refinery Pier just south of Highway 580 (“Wharf station”). Between these two stations lies a mountain ridge that extends in the southeast direction from Point San Pablo. Based on an evaluation of the wind patterns from these two stations, conditions at the Gertrude station are more representative of the majority of the Facility area (north and east of the mountain ridge), while conditions at the Wharf station are more representative of the Facility area to the south and west of the mountain ridge.

Therefore, both datasets were processed using AERMET version 12345. The data from October 1, 2009 to September 30, 2010 for each station were processed to ensure the 90% completeness criteria required by the EPA is met (EPA, 2005).¹³ The two on-site surface air stations, together with the surface pressure and cloud cover data from Oakland International Airport surface station, and upper air data from the Oakland International Airport upper air station, were used in the processing.

¹³ More information on meteorological data processing performed for this analysis is presented in Attachment 2 of Appendix 4.3-CHRA.

Most of the construction activities and related traffic, with a few exceptions, occur to the north of the mountain ridge, and therefore AERMOD-ready meteorological data processed for the Gertrude station was used for the air dispersion modeling of these construction emissions. The exceptions are the existing storage tank domed roof installation project, which occurs to the south of the mountain ridge.¹⁴ As a result, the off-road equipment activities associated with this construction project were modeled using the AERMOD-ready meteorological data processed for the Wharf station. Other activities modeled using the Wharf station data are the on-site delivery truck and flatbed idling activities of the existing storage tank doomed roof installation. Note that although the existing storage tank domed roof installation project occurs to the south of the mountain ridge, the majority of the travel path of the on-site delivery truck and flatbed running from the Facility laydown area to the construction area is to the north of the mountain ridge. As a result, the on-site delivery truck and flatbed running activities of the tank roof installation project was modeled using the Gertrude station data. Similarly, the on-site worker trips associated with the roof installation project was also modeled using the Gertrude station data.

1.2.7 Terrain

AERMOD uses a terrain preprocessor, AERMAP version 11103,¹⁵ to determine elevations of the surrounding landscape. Data from the National Elevation Data (NED) set, available from the United States Geological Survey,¹⁶ was utilized to import the elevation information for sources and receptors. AERMAP was used to extract elevations from the NED dataset. NED 1/3 arc-second data do not provide sufficient resolution in elevations for the mountain ridge area near the Modernization Project site, where some of the modeled worker receptors are located. Although the higher resolution NED 1/9 arc-second data set does provide sufficient resolution for these receptors, it does not have elevation information over water. To ensure sufficient resolution and coverage for receptor elevations for the AERMAP run, NED 1/9 arc-second data were used, supplemented by the 1/3 arc-second data for water areas.

¹⁴ According to Chevron Data Transmittal #31 (Rev #3), 2012, the tank dome installation can occur within a big area. The smaller area close to the Facility boundary and off-site residential receptors as shown in Figure A4.3-CHRA-3 was conservatively selected to represent the dome installation area.

¹⁵ More information on the model and the executable can be found at: http://www.epa.gov/ttn/scram/dispersion_related.htm.

¹⁶ NED data available at: <http://seamless.usgs.gov/website/seamless/viewer.htm>

1.2.7.1 Rural or Urban Boundary Layer Options

An important consideration in an air dispersion modeling analysis is the selection of rural or urban dispersion coefficients, which are influenced by the level of development (i.e., height of buildings and urban heat island effect) in the vicinity of the Modernization Project. Due to the proximity of the project to open water (which has no buildings or any heat generating sources), the models use rural dispersion coefficients, which is consistent with EPA guidance (EPA, 2009).

1.2.8 Model Averaging Periods and Unit Emissions Dispersion Factor Method

Calculation of chemical concentrations for use in exposure analysis requires the selection of appropriate concentration averaging times. In accordance with OEHHA guidance (OEHHA, 2003), annual average concentrations were estimated and used to evaluate cancer risk, chronic non-cancer and $PM_{2.5}$ impacts. Acute non-cancer impacts were estimated using the maximum 1-hour concentration.

Construction emissions were modeled using the unit emissions dispersion factor method, such that emission source groups are input to the model with unit average annual emission rates (i.e., 1 gram per second [g/s]), and the model estimates 1-hour maximum or annual average dispersion factors (with units of micrograms per square meter [$\mu\text{g}/\text{m}^3$]/[g/s]). To calculate annual average ambient air concentrations, the annual average dispersion factors were multiplied by the annual emission rates. Details on the steps taken in the database are also described in Attachment 3 of *Appendix 4.3-HRA*.

For acute non-cancer hazard analyses, the estimated 1-hour maximum dispersion factors for each source group were used. These dispersion factors were multiplied by the maximum 1-hour emission rate to determine the maximum 1-hour concentration for a given source group. Note that because the maximum emissions for each group are not expected to occur during the same hour of the year, summing the maximum 1-hour concentrations across all source groups yields conservative (i.e., overestimates of) total air concentrations. Attachment 3 of the *Appendix 4.3-HRA* contains the database inputs that were used to combine 1-hour maximum dispersion factors and actual emission rates to yield 1-hour air concentrations and to conduct further acute non-cancer hazard calculation.

The dispersion factors by source group for the maximum exposed individuals are presented in Attachment 2.

1.2.9 Model Adjustment Factors

Cal/EPA recommends applying a model adjustment factor (MAF) to air concentrations based on a continuous averaging period (i.e., 24 hours per day, 365 days per year) when the following three things are true: (1) the actual exposure occurs for less than 24 hours per day and/or less than 1 year; (2) emission activities occur for less than 24 hours per day and/or less than 1 year; and (3) exposures are entirely or partially concurrent with emitting activities (OEHHA, 2003). The model averages the emissions over 24 hour per day over a year. The modeling adjustment factor is applied to the modeled annual average concentrations to reflect the fact that the actual exposure concentration the receptor is exposed to is higher than the average annual concentration. The MAFs are presented in Table A4.3-CHRA-6 and discussed below.

For the Modernization Project, actual construction is expected to occur for 11 hours per day between 6:00 a.m. and 5:00 p.m. Therefore, an MAF must be applied to certain populations, as discussed below.

Residents have an exposure time 24 hours per day, 7 days a week. This assumption is consistent with the modeled annual average air concentration (which is averaged over 24 hours per day). Thus, the annual average concentration need not be adjusted for residents.

However, a MAF was applied to populations that are present during the construction activity, but that are not present 24 hours per day, 7 days per week. As stated above, actual Modernization Project construction is expected to occur for 11 hours per day, 5 days per week. As recommended by OEHHA (2003), a MAF of 3.36 was applied to the annual average concentration for the daycare child and school child to account for the differences between construction schedule and the exposure schedule ($([24 \text{ hours}/10 \text{ hours}]^{17} \times [7 \text{ days}/5 \text{ days}]) = 3.36$). These adjusted concentrations represent the theoretical maximum 10-hour concentrations over the operating period to which the off-site daycare children might be exposed.

The exposure point concentrations for the daycare child and school child receptors were calculated using the following equation:

¹⁷ Ten hours was used instead of 11 hours to determine a conservative (overestimated) exposure concentration. Using 11 hours would result in a lower exposure concentration.

$$C_i = C_{i,annual} \times MAF$$

Where:

- C_i = Exposure Point Concentration of Chemical_i (µg/m³)
 $C_{i,annual}$ = Annual Average Concentration of Chemical_i (µg/m³)
 MAF = Modeling adjustment factor (unitless)

1.3 HEALTH EFFECT CHARACTERIZATION METHODS

The following sections discuss the various components required for conducting this risk assessment in detail. Attachment 3 of the *Appendix 4.3-HRA* contains a description of the Microsoft Access databases that were used to calculate air concentrations and to conduct further health risk estimations based on the methodology described below. These databases mimic the calculation method used in the CARB Hotspots Analysis Reporting Program and its On-Ramp extension. Attachment 3 of the *Appendix 4.3-HRA* describes in detail on how these databases works and equivalency tests conducted to prove that these databases and Hotspots Analysis Reporting Program will generate same risk values when using the same inputs.

1.3.1 Exposure Assessment

1.3.1.1 Exposed Populations

As described earlier, the potentially exposed populations¹⁸ evaluated in this assessment are:

- Residents (children and adults);
- School children;
- Daycare children;
- Community center children and adults;
- Patient children and adults;
- Recreational facility children and adults;
- Adult workers.

A maximum exposed individual sensitive receptor (MEISR) is identified as the sensitive receptor (among all of the potential exposed sensitive populations) with the highest estimated cancer risk, chronic non-cancer impact, or acute non-

¹⁸ Although neither recreational adult or children nor workers are sensitive receptors under BAAQMD guidance, these receptors were included for completeness.

cancer health impact. In addition, a MEISR is also identified for the $PM_{2.5}$ concentration. In order to identify the MEISR for each health impact, the impacts were calculated for all receptors in the modeling domain.

In addition, a set of boundary receptors was also included in the model. Note that because no sensitive populations will reside at the boundary receptor locations for long periods, they would not experience chronic exposure; therefore, these boundary receptors were included for acute health impact analysis only.

The exposure parameters used for estimating excess lifetime cancer risks for all potentially exposed populations were obtained using risk assessment guidelines from OEHHA (2003) and BAAQMD (2010a), unless otherwise noted, and are presented in Tables A4.3-CHRA-7a and 7b.

As mentioned above, some Modernization Project construction was completed in 2008-2009. In order to capture the most conservative estimates of cancer risk impacts, two scenarios based on different exposure periods were evaluated: one scenario assumed that the evaluated receptor was present at the start of the completed construction in 2008, and would remain through the end of future construction; and the other scenario assumed the receptor would be present for future construction only.¹⁹ Take residential receptor as an example, the first scenario assumes that a residential child reached third trimester as a fetus in utero at the start of the completed construction, and was exposed to the entire completed construction emissions until the construction ceased. This residential child will continue grow to about 6 years old until the future construction begins and will be exposed to the entire future construction emissions. The second scenario assumes that a residential child reaches third trimester as a fetus in utero at the start of the future construction and will be exposed to the entire future construction, only. The exposure parameters used for estimating excess lifetime cancer risks for all potentially exposed populations under these two scenarios are presented in Tables A4.3-CHRA-7a and A4.3-CHRA-7b, respectively.

¹⁹ The child resident reflects the most conservative exposure among all populations evaluated. To capture the worst case cancer risk estimate, for a resident child, one scenario assumes that the fetus reached its third trimester when the existing construction started in 2008. Therefore the baby will be exposed to both the completed and future construction emissions. The second scenario assumes that the fetus reaches its third trimester when the future construction starts in 2014. Therefore the baby will be exposed to the future construction only. Similarly, other sensitive child receptors such as a daycare child and school child were also evaluated under these two scenarios.

1.3.1.2 Calculation of Intake

The dose estimated for each exposure pathway is a function of the concentration of a chemical and the intake of that chemical.

The intake factor for inhalation, IF_{inh} , can be calculated as follows:

$$IF_{inh} = \frac{DBR * ET * EF * ED * CF}{AT}$$

Where:

IF_{inh}	=	Intake Factor for Inhalation (m ³ /kg-day)
DBR	=	Daily Breathing Rate (L/kg-day)
ET	=	Exposure Time (hours/24 hours)
EF	=	Exposure Frequency (days/year)
ED	=	Exposure Duration (years)
AT	=	Averaging Time (days)
CF	=	Conversion Factor, 0.001 (m ³ /L)

The chemical intake or dose is estimated by multiplying the inhalation intake factor, IF_{inh} , by the chemical concentration in the air, C_i . This calculation is based on the dose algorithm given in OEHHA Hot Spots guidance (OEHHA, 2003).

1.3.2 Toxicity Assessment

The toxicity assessment characterizes the relationship between the magnitude of exposure and the nature and magnitude of adverse health effects that may result from such exposure. For purposes of calculating exposure criteria to be used in risk assessments, adverse health effects are classified into two broad categories – cancer and non-cancer endpoints. Toxicity values used to estimate the likelihood of adverse effects occurring in humans at different exposure levels are identified as part of the toxicity assessment component of a risk assessment.

All chemicals emitted from operations that were identified in the BAAQMD Regulation 2 Rule 5, and for which OEHHA provides quantitative toxicity information were included in this analysis. Diesel exhaust, a complex mixture that includes hundreds of individual constituents, is identified by the State of California as a known carcinogen. Under California regulatory guidelines, DPM is used as a surrogate measure of carcinogen exposure for the mixture of chemicals that make up diesel exhaust as a whole. There is currently no acute non-cancer toxicity value available for DPM. Thus, no acute health impacts were

calculated for diesel equipment operations in this evaluation. Besides DPM, 14 other TACs were also evaluated in this HRA. The chemicals and the toxicity values for the chemicals evaluated in this analysis are summarized in Table A4.3-CHRA-1 and described below.

1.3.3 Construction

Cancer risk and chronic non-cancer hazard associated with construction are based on DPM concentrations from the off-road construction equipment and diesel on-road vehicles, and on speciated gasoline exhaust and evaporative TOGs from the gasoline on-road vehicles.

As discussed in *Appendix 4.3-CST*, off-road equipment emissions were evaluated assuming that all off-road equipment use diesel fuel, even though Chevron has indicated that some off-road equipment may use gasoline or other alternative fuel. This approach is conservative from a health risk analysis standpoint because diesel equipment usually contributes higher health risks for exposed populations than equipment using gasoline or other alternative fuel.

As also discussed in *Appendix 4.3-CST*, on-road delivery truck, flatbeds, and haul truck emissions were evaluated assuming that these trucks are diesel fueled. However, some portion of the on-road cars, buses, and pickups for construction worker commuting and transporting are gasoline fueled. The gasoline exhaust and evaporative TOGs were speciated for cancer risk and chronic non-cancer hazard calculation (BAAQMD, 2012).

The acute non-cancer hazard is based on speciated gasoline exhaust and evaporative TOGs (BAAQMD, 2010a).

1.4 CANCER RISK ADJUSTMENT FACTOR

The BAAQMD recommends estimation of cancer risk using methods from OEHHA's Technical Support Document for Cancer Potency Factors: Methodologies for Derivation, Listing of Available Values, and Adjustment to Allow for Early Life Stage Exposures (Cal/EPA, 2009). The OEHHA Technical Support Document proposes the use of age-specific sensitivity factors to account for an "anticipated sensitivity to carcinogens" of infants and children. Under the revised approach, cancer risk estimates are weighted by a factor of 10 for exposures that occur from the third trimester of pregnancy to 2 years of age and by a factor of 3 for exposures that occur from 2 years to 16 years of age. The cancer risk adjustment factor (CRAF) is the weighted factor over the entire exposure duration.

Cancer risks associated with construction were adjusted using CRAFs for all child receptor types: resident child, daycare child, community center child, school child, patient child, and recreational child. All adult populations were assumed to be over 16 years old; therefore, no weighting factor was applied in the cancer risks estimations for these populations.

As mentioned above, for sensitive child receptors, two exposure scenarios were evaluated. CRAFs were applied accordingly based on the assumed birth year and exposure duration for each receptor population in each scenario. Tables A4.3-CHRA-8a and b shows the CRAFs used for each receptor type in each scenario.

1.5 HEALTH EFFECTS

1.5.1 Estimation of Cancer Risks

Excess lifetime cancer risks are estimated as the upper-bound incremental probability that an individual will develop cancer over a lifetime as a direct result of exposure to potential carcinogens. The estimated risk is expressed as a unitless probability. The cancer risk attributed to a chemical is calculated by multiplying the chemical intake or dose at the human exchange boundaries (e.g., lungs) by the chemical-specific cancer potency factor (CPF).

The equation used to calculate the potential excess lifetime cancer risk for the inhalation pathway is as follows:

$$\text{Risk}_{\text{inh}} = \sum C_i \times CF \times \text{IF}_{\text{inh}} \times \text{CPF}_i \times \text{CRAF}$$

Where:

Risk_{inh}	=	Cancer Risk; the incremental probability of an individual developing cancer as a result of inhalation exposure to a particular potential carcinogen (unitless)
C_i ($\mu\text{g}/\text{m}^3$)	=	Annual Average Air Concentration for Chemical _i
CF	=	Conversion Factor (mg/ μg)
IF_{inh}	=	Intake Factor for Inhalation ($\text{m}^3/\text{kg}\cdot\text{day}$)
CPF_i	=	Cancer Potency Factor for Chemical _i (mg chemical/kg body weight-day) ⁻¹
CRAF	=	Cancer Risk Adjustment Factor (unitless)

1.5.2 Estimation of Chronic Non-Cancer Hazard Quotients/Indices

The potential for exposure to result in chronic non-cancer effects is evaluated by comparing the estimated annual average air concentration (which is equivalent to the average daily air concentration) to the chemical-specific non-cancer chronic reference exposure levels (RELs). When calculated for a single chemical, the comparison yields a ratio termed a hazard quotient (HQ). To evaluate the potential for adverse chronic non-cancer health effects from simultaneous exposure to multiple chemicals, the HQs for all chemicals are summed, yielding an HI.

The equations used to calculate the chemical-specific HQs and the overall HI are:

$$\text{Chronic HQ}_i = C_i / \text{cREL}_i$$

$$\text{Chronic HI} = \sum \text{HQ}_i$$

Where:

Chronic HQ_i = Chronic Hazard Quotient for Chemical_i
(unitless)

Chronic HI = Hazard Index (unitless)

C_i = Annual Average Air Concentration for
Chemical_i (µg/m³)

cREL_i = Chronic Non-cancer Reference Exposure
Level for Chemical_i (µg/m³)

1.5.3 Estimation of Acute Non-Cancer Hazard Quotients/Indices

The potential for exposure to result in acute non-cancer effects is evaluated by comparing the estimated one-hour maximum air concentration to the chemical-specific non-cancer acute RELs. The estimation method for determining the 1-hr maximum concentration was described in the “Air Dispersion Modeling” section. When calculated for a single chemical, the comparison yields a ratio termed a hazard quotient or HQ. To evaluate the potential for adverse acute non-cancer health effects from simultaneous exposure to multiple chemicals, the HQs for all chemicals are summed, yielding an HI.

The equations used to calculate the chemical-specific HQs and the overall HI are:

$$\text{Acute HQ}_i = C_i / \text{aREL}_i$$

$$\text{Acute HI} = \sum \text{HQ}_i$$

Where:

Acute HQ _i	=	Acute Hazard Quotient for Chemical _i (unitless)
Acute HI	=	Hazard Index (unitless)
C _i	=	1-hour Maximum Air Concentration for Chemical _i (µg/m ³)
aREL _i	=	Acute Non-cancer Reference Exposure Level for Chemical _i (µg/m ³)

1.6 SUMMARY OF RESULTS

1.6.1 Construction

Table A4.3-CHRA-9a summarizes the cancer risk, chronic HI, PM_{2.5} concentration, and acute HI at the off-site MEISR for: (1) completed and future construction together; and (2) future construction only. Figure A4.3-CHRA-25a-d shows the cancer risk, chronic HI, acute HI and PM_{2.5} related to future construction activities. All health impacts are below the CEQA significance thresholds, and the acute and chronic noncancer health impacts are far below CEQA significance thresholds. Table A4.3-CHRA-9b shows the chemical breakdown that result in the health impacts. As can be seen from Table A4.3-CHRA-9b, the bulk of the cancer risks results from diesel particulate matter were emitted by offroad construction equipment.

1.7 HEALTH IMPACT FROM CONSTRUCTION OF THE MODERNIZATION PROJECT MITIGATION MEASURES

Chevron May construct a 2-megawatt (MW) ground-mounted photovoltaic solar facility on approximately 13 acres of Chevron property, located adjacent to Castro St. as a GHG mitigation measure (Chevron Data Transmittal #43, 2013). In addition, Chevron may install up to 14 tank domes to offset any potential Modernization Project ROG emissions increases. The section below discusses the methodology used to quantify health impact from the construction of these mitigation measures.

1.7.1 Health Impact from Construction of the 2-MW Solar Facility

Emissions used to evaluate impact from construction of the 2-MW solar facility was presented in *Appendix 4.3-CST*. It was conservatively assumed that the construction of the solar facility starts in January of 2014. The health impact was then quantified using the methodology described in Sections 1.1 and 1.2, The

emissions associated with the construction of the 2-MW solar facility are described in Table 4.3-CST-19. Table A4.3-CHRA-10 presents the health impact from construction of the 2-MW solar facility.

1.7.2 Health Impact from Construction of 14 Tank Domes

Emissions used to evaluate impact from construction of the 14 tank domes was presented in *Appendix 4.3-CST*. The exposure assumption was that the residential child reaches third trimester as a fetus in uterus in January 2014, when the one tank dome is constructed as one of the project design features. The first of the 14 tanks will be constructed in 2016 when the residential child is almost 2 years old, and the construction schedule of the tank domes is one at a time and two per year (Chevron Data Transmittal #36O (Rev #3), 2014). Therefore, it will take approximately 7 years to construct all 14 tank domes. The emissions associated with the construction of the 14 tank domes are described in Table 4.3-CST-21. The locations of sources for the 14 tank domes are shown in Figure A4.3-CHRA-3.²⁰ Table A4.3-CHRA-11a presents the calculated intake factor for this residential child. Table A4.3-CHRA-11b presents the health impact from construction of the 14 tank domes.

²⁰ According to Chevron Data Transmittal #31 (Rev #3, 2012), the tank dome installation can occur within a big area. The smaller area close to the Facility boundary and off-site residential receptors as shown in Figure A4.3-CHRA-3 was conservatively selected to represent the dome installation area.

Construction Off-road Equipment Modeling Source Parameters
Chevron Modernization Project
Richmond, California

Phase	Source Group ¹	Source	Source Type	Source Dimension	Number of Sources	Release Height	Initial Vertical Dimension	Initial Lateral Dimension	Notes
				[m]		[m]	[m]	[m]	
Existing Hydrogen Plant	EXISH2	Construction Offroad Equipment	Volume	20	44	5	1.4	4.7	2,3,4,5,6,7
Hydrogen Plant Tie-In	TI		Volume	10	179	5	1.4	2.3	2,3,4,5,6,7
Hydrogen Plant Replacement (New Hydrogen Plant)	NEWH2		Volume	20	156	5	1.4	4.7	2,3,4,5,6,7
Sulfur Recovery Unit (SRU)	SRU		Volume	20	223	5	1.4	4.7	2,3,4,5,6,7
Fluid Catalytic Cracking Unit Feed Hydrotreater (FCCFHT, or TKC)	TKC		Volume	20	367	5	1.4	4.7	2,3,4,5,6,7
Project Water Reuse	WAT		Volume	20	449	5	1.4	4.7	2,3,4,5,6,7
Existing Storage Tank Domed Roof Installation	TKD		Volume	20	204	5	1.4	4.7	2,3,4,5,6,7

Notes:

1. Source groups are the names used in the air dispersion modeling. Dispersion factors were generated for each of the source groups separately.
2. Due to lack of specific instructions on modeling of construction emissions from BAAQMD, ENVIRON used SCAQMD LST methodology when setting up the model. for construction offroad equipment. According to the LST methodology, construction sources were modeled as adjacent volume sources.
3. For volume sources, source dimensions were determined by area of construction zone for each phase. 20-m volume sources were used for all phases except for Hydrogen Plant tie-in. Since the tie-in construction area is expected to occur on a long and skinny piece of land, ENVIRON used smaller volume sources to better represent the geometry of the construction zone.
4. Number of sources were determined by area of construction zone and source dimensions for the same phase.
5. According to the LST methodology, release height of the modeled volume sources representing construction equipment was set to 5 meters.
6. According to the LST methodology, initial vertical dimension of the modeled volume sources was set to 1.4 meters.
7. According to USEPA ISC3 User's Guide Volume II, initial lateral dimension of single volume sources is length of side divided by 4.3.

Notes:

1. Source groups are the names used in the air dispersion modeling. Dispersion factors were generated for each of the source groups separately.
2. ENVIRON used non-adjacent volume sources to model onroad vehicle running emissions.
3. For volume sources, source dimensions were determined by the roadway width where the source is placed. The volume source is placed such that the roadway width is just covered by the volume source.
4. ENVIRON used 50-m spacing between volume sources. Number of sources were determined by the length of the roadway segment.
5. Consistent with ARB approved methodology (personal communication Gavin Hoch of ENVIRON by telephone with Jing Yuan of ARB on August 24, 2006), release height of the modeled volume sources representing non-truck onroad vehicles was set to 0.6 m.
6. According to USEPA ISC3 User's Guide Volume II, initial vertical dimension of elevated volume sources not on or adjacent to a building is release height divided by 4.3.
7. According to USEPA ISC3 User's Guide Volume II, initial lateral dimension of single volume sources is length of side divided by 4.3.
8. Consistent with BAAQMD recommendations for Health Risk Assessments & Land Use, release height of the modeled volume sources representing truck onroad vehicles was set to 4.57m.
9. ENVIRON used area sources to model onroad vehicle idling emissions.
10. Consistent with BAAQMD recommendations for Health Risk Assessments & Land Use, release height of the modeled area sources representing truck idling was set to 4.57m.
11. According to USEPA ISC3 User's Guide Volume II, initial vertical dimension of elevated area sources is release height divided by 4.3.

Table A4.3-CHRA-6
Modeling Adjustment Factors - Construction
Chevron Modernization Project
Richmond, California

Receptor	Modeling Adjustment Factor (MAF)	Note
Resident Adult	1	a
Resident Child	1	a
Worker	3.4	b
School Child	3.4	b
Day Care Child	3.4	b
Adult Patient	1	a
Child Patient	1	a
Recreational Adult	3.4	b
Recreational Child	3.4	b
Community Center Child	3.4	b

Notes:

- a. Modeling adjustment factor is not needed for residents and patients because they were assumed to be present 24 hours per day, 7 days per week.
- b. A worker, a school child, a daycare child, a recreational user or a community center child was not present 24 hours per day, 7 days per week, but emissions were averaged over 24 hours per day, 7 days per week in the air dispersion model and the construction schedule was 10 hours per day, 5 days per week. Thus, an adjustment factor of 3.4 (equal to $[24 \text{ hours}/10 \text{ hours}] \times [7 \text{ days}/5 \text{ days}]$) was applied to the annual average concentrations to account for the actual exposure concentrations for these receptor types.

Notes:

1. Intake factors were calculated for each single year for the previous construction duration of 2008-2009 and the future construction duration of 2014-2016 to be consistent with air concentration modeling. The construction durations were partial of the year for 2008 and 2009, but to be consistent with the modeled annual average air concentrations, the exposure durations were assumed to be the whole year.
2. Exposure parameters other than exposure duration reflect default values for residents from BAAQMD 2010.
3. Exposure parameters other than exposure duration reflect default values for workers from BAAQMD 2010. The daily breathing rate for a worker corresponds to an hourly breathing rate of 1.3 m³/hour for eight hours.
4. Exposure parameters other than exposure duration reflect default values for students from BAAQMD 2010.
5. Daily breathing rates for day care child receptors reflect default breathing rates for children from BAAQMD 2010. The day care centers were assumed to operate 10 hours per day from 7 AM to 5 PM. The day care child receptor was assumed to be at a day care center while the parents are at work; 245 days reflects the default exposure frequency for a worker from BAAQMD 2010. Usually, the day care centers are assumed to accept children from 6 weeks to 6 years old. Therefore, if a child is assumed to attend the daycare facility at age of 6 weeks in July 2008 (the beginning of the construction), he or she will not be present in the day care center when he or she turns 6 years old in May 2014 and in the entire year of 2015 and 2016.
6. Adult patient was assumed to be 16 years old and above, and stay in hospital for the whole construction period. Daily breathing rate and exposure time for adult patients reflect default values for resident adults from BAAQMD 2010.
7. Child patient was assumed to be in hospital for the whole construction period. Daily breathing rate and exposure time for child patients reflect default values for resident children from BAAQMD 2010.
8. Hourly breathing rates for recreational child and adult receptors reflect recommended mean breathing rates based on moderate activities for short-term exposures for age groups from birth to 9 years and from 16 years to 70 years from USEPA 2011. The recreational child and adult receptors were conservatively assumed to be at a recreational location 1 hours per day, once a week, every week (52 weeks) of the year.
9. For the child receptors at community center, the exposure parameters were conservatively assumed to be the same as those for day care child.

BAAQMD Threshold					10	1.0	0.3	1.0

Notes:

1. The excess lifetime cancer risk assumes that an individual adjacent to the construction activity is exposed to construction emissions from (1) completed and future construction; (2) future construction only. Cancer risks are estimated as the upper-bound incremental probability that an individual will develop cancer over a lifetime as a direct result of exposure to potential carcinogens. The estimated risk is expressed as a unitless probability. The cancer risks attributed to the DPM and gasoline TOG emissions associated with the Project were calculated based on the DPM and TOG exposure point concentration (C), the intake factors presented in Tables 4.3-CHRA-7a and 7b, the CPF presented in Table 4.3-CHRA-1, and the CRAFs presented in Table 4.3-CHRA-8a and 8b.

Calculation:

$Risk_{inh} = \sum(C_i \times MAF \times CF \times IF_{inh} \times CPF_i \times ASF)$
Where:
Risk_{inh} = Cancer Risk; the incremental probability of an individual developing cancer as a result of inhalation exposure to a particular potential carcinogen (unitless)
C_i = Modeled Annual Average Concentration in air for Chemical I (µg/m³)
MAF = Modeling Adjustment Factor
CF = Conversion Factor (mg/µg)
IF_{inh} = Intake Factor for Inhalation (m³/kg-day)
CPF_i = Cancer Potency Factor for Chemical I (mg chemical/kg body weight-day)
ASF = Age Sensitivity Factor

2. The potential for exposure to result in chronic noncancer effects is evaluated by comparing the estimated annual average air concentration (which is equivalent to the average daily air concentration) to the chemical-specific noncancer chronic RELs. When calculated for a single chemical, the comparison yields a ratio termed a hazard quotient. The hazard quotients were then summed for all chemicals to yield the hazard index. The hazard quotients were calculated based on the modeled annual average DPM and TOG concentrations and the chronic REL presented in Table 4.3-CHRA-1.

Calculation:

$HQ_i = C_i / REL_i$; $HI = \sum HQ_i$
Where:
HI = Hazard Index
HQ_i = Hazard Quotient for Chemical I
C = Average Daily Air Concentration for Chemical I (µg/m³)
REL_i = Noncancer Reference Exposure Level for Chemical I (µg/m³)

3. The MEISR is the offsite receptor location with the maximum annual average PM_{2.5} concentration from the modeled construction sources. The PM_{2.5} concentration takes into account emissions from off-road equipment exhaust, on road vehicles exhaust, on road vehicles brake wear and tire wear, and fugitive dust emissions.

4. ENVIRON evaluated the acute hazard indices (HIs) for the maximum hourly construction emissions scenarios. In order to find the maximum hour, ENVIRON calculated emissions by source group by each quarter of the construction year, from (1) completed and future construction; (2) future construction only. Then these emissions were applied to the modeled maximum 1-hour dispersion factors to get concentrations by source group, quarter and year. The concentrations were then summed across all source groups to yield maximum 1-hour concentration by quarter and year. The maximum across all quarters were chosen as the maximum hour. The potential for exposure to result in acute noncancer effects is evaluated by comparing the estimated maximum hourly air concentration to the chemical-specific noncancer acute RELs. When calculated for a single chemical, the comparison yields a ratio termed a hazard quotient. The acute HI is calculated by summing all hazard quotients.

Calculation:

$Acute\ HI = \sum Acute\ HQ_i = \sum C_i / REL_i$
Where:
Acute HI = Acute Hazard Index
Acute HQ_i = Acute Hazard Quotient for Chemical i
C_i = Max hourly Air Concentration for Chemical i (µg/m3)
REL_i = Noncancer Reference Exposure Level for Chemical i (µg/m3)

APPENDIX 4.3 - CST

CST: Construction Criteria Air Pollutant, Toxic Air Contaminant, and Greenhouse Gas Emissions

APPENDIX 4.3-CST

CONSTRUCTION CRITERIA AIR POLLUTANT, TOXIC AIR CONTAMINANT, AND GREENHOUSE GAS EMISSIONS

This appendix describes the methods, data, and assumptions used to estimate criteria air pollutants (CAPs), greenhouse gas (GHG), and toxic air contaminant (TAC) emissions from completed and future construction activities associated with the Modernization Project. Operational refinery emissions are discussed in *Appendix 4.3-OP*. Emissions associated with transporting feedstock to and products from the Facility via ship are considered in *Appendix 4.3-SHP*. Emissions associated material transport by rail and truck to and from the Facility are discussed in *Appendix 4.3-TRANS*.

A detailed discussion of construction phases is presented in Table A4.3-CST-1 and is also summarized in *Chapter 3, Project Description*, of this EIR, and Figures A4.3-CST-1 and A4.3-CST-2 show the locations of the construction phases. The phase names reflect the associated Project component: Hydrogen Plant Replacement (also referred to as new hydrogen plant), existing hydrogen plant dismantling (also referred to as existing hydrogen plant), Sulfur Removal Improvements (previously referred to as “hydrogen purity”), Project Design Features (existing storage tank domed roof installation, Project water reuse, and light emitting diode [LED] lighting)¹ (Chevron Data Transmittal #47A (Rev #6), 2014), and related piping and other ancillary equipment (hydrogen plant tie-in). These construction phases involve emission-generating sources such as off-road construction equipment, delivery trucks, flatbed trucks, haul trucks, worker commuting vehicles, worker transport vehicles, paving and coating activities, and fugitive dust.

¹ Construction associated with LED lighting is expected to be negligible. Also the emissions associated with the Fluid Catalytic Cracker Cooling Water Tower Motor Upgrade was not quantified due to the short duration of the activity (Chevron Data Transmittal #36O (Rev #3), 2014, Attachment 9).

1.1 CONSTRUCTION CRITERIA POLLUTANT EMISSIONS

1.1.1 Source Identification, Physical Scope, and Temporal Scenarios for Construction Emissions

This section discusses the emissions estimation of CAPs and GHGs associated with the construction of the Modernization Project. There are four general types of construction CAP sources:

- Off-road construction equipment
- On-road mobile sources
- Architectural coatings and paving
- Fugitive dust sources

There are two general types of construction GHG sources:

- Off-road construction equipment
- On-road mobile sources

Table A4.3-CST-2 presents examples for each source category, and describes the types and location of CAP and GHG emissions.

1.1.1.1 Definition of On-Site and Off-Site Activity

In this section, any construction activity that occurs within the Facility boundary shown in Figure A4.3-CST-3 is defined as on-site activity. Similarly, any activity that occurs outside of the Facility boundary is defined as off-site activity. “On-site” and “off-site” are terms that refer to the location where emissions occur, are not to be confused with the terms “on-road” and “off-road,” which refer to types of engine emission sources. The location of TAC emissions is important for the health risk assessment (HRA), as will be discussed later in this section.

1.1.1.2 Physical Domain for CAP and GHG Emissions Inventory

To evaluate criteria pollutant and mass emission impacts, the sum of emissions from on-site and off-site activity was compared to the California Environmental Quality Act (CEQA) Significance Thresholds for construction. The GHG emissions were also estimated by summing the emissions from on-site and off-site activity. On-road vehicle travel associated with the construction will occur both on site and off site. For the CAP and GHG emissions inventory, because the actual off-site destinations of these vehicles were unknown, the emissions associated with off-site, on-road vehicle travel were calculated assuming a truck trip length of 20 miles per one-way trip, and a worker trip length of 12.4 miles per one-way trip,

Chevron Refinery Modernization Project EIR
Construction Phases and Areas (2) - Project Design Features

based on CalEEMod™ default values (ENVIRON, 2013). This is a reasonable assumption for evaluating the emissions of criteria pollutants at a regional level.

1.1.1.3 Temporal Scenarios: Completed Construction and Future Construction

Chevron began construction of certain portions of the Modernization Project in 2008, but halted construction in 2009 following an injunction from the California Court of Appeal. This portion of the construction, which is already completed, is referred to as “completed construction” in this appendix.

The remaining part of the Modernization Project to be built will be referred to as “future construction” in this appendix. For this analysis, future construction is assumed to begin in 2014 and continue through 2015 (Chevron Data Transmittal #360 (Rev #3), 2014).² According to Chevron, the existing hydrogen plant dismantling will occur after the new hydrogen plant starts to operate (Chevron Data Transmittal #360 (Rev #3), 2014). Therefore, dismantling of existing hydrogen plant was assumed to occur in 2016. Activity data were provided separately for the “completed construction” and the “future construction” periods. Both construction periods were included in the analysis.

1.1.2 Overview of Construction Emissions Estimation

The California Air Resources Board (CARB) 2011 In-Use Off-Road Equipment Inventory Model (OFFROAD 2011), and EMission FACtor Model (EMFAC2011), together with construction schedule and activity data provided by Chevron were used to calculate emissions. When site-specific data were not available, default assumptions consistent with CalEEMod™ were used. This methodology is consistent with CalEEMod™ and is capable of incorporating the detailed activity data Chevron provided.

Tables A4.3-CST-3a, b, and c show the emission calculation methodologies for construction emission sources. More details regarding emissions estimation of construction CAPs and GHGs are provided below, with a discussion of activity data followed by emission factors.

² Chevron Data Transmittal #360 (Rev#3), 2014 provides equipment data for eight consecutive quarters. Because the exact start date of future construction is uncertain, the emissions analysis conservatively uses emission factors for 2014 for the first four quarters of construction, and 2015 emission factors for the last four quarters of construction. A construction start date later than January 2014 would lead to lower emissions than predicted here as the emissions profile of the construction fleet is cleaner, due to the implementation of regulations requiring lower emissions engines.

1.1.3 On-Site Construction Activity: Emission Sources

1.1.3.1 Off-Road Equipment

1.1.3.1.1 On-Site Off-Road Activity Data

For construction off-road equipment (e.g., excavators, graders, cranes, manlifts, etc.), activity data provided by Chevron included equipment counts by equipment type and construction area, for each quarter/month of each construction year³ (Chevron Data Transmittals #20 (Rev #1), 2013; #36O (Rev #3), 2014). In the absence of site-specific information, equipment load factors and horsepower ratings were based on CalEEMod™ default values. This equipment was assumed to operate for every workday of the quarter/month. In addition, the number of operating hours per work day was also provided by Chevron (Chevron Data Transmittal #20 (Rev #1), 2013; #36O (Rev #3), 2014).

Tables A4.3-CST-4a and b show the equipment list and activity data provided by Chevron for off-road equipment.

1.1.3.1.2 On-Site Off-Road Emission Factors

Emission factors for off-road equipment are based on CARB's OFFROAD 2011, and engine tier standard specified in 13 California Code of Regulations (CCR) 2423(b)(1) (CARB, 2007). The model includes emission factors for oxides of nitrogen (NO_x), particulate matter, carbon monoxide (CO), hydrocarbons, total organic gases (TOGs), nitrous oxide (N₂O), methane (CH₄), and carbon dioxide (CO₂). The particulate matter emission factor is used to estimate particulate matter—both respirable particulates (PM₁₀) and fine particulates (PM_{2.5}), and the hydrocarbon and TOG emission factors are used to estimate reactive organic gas (ROG) emissions. Hydrocarbon emission factors from the United States Environmental Protection Agency (EPA)/CARB tier standards were used to calculate ROG emissions for completed construction, while TOG emission factors were used to calculate ROG emissions for future construction.⁴

Tables A4.3-CST-5a and b summarize the emission factors used for off-road equipment in this analysis. Details on assumptions associated with these emission factors are described below.

³ For the components of the Modernization projects, activity data was provided for each quarter of each construction year. For the project design features, activity data was provided for each month of each construction year.

⁴ The tier standards regulate hydrocarbons rather than TOG, while the OFFROAD 2011 model presents TOG rather than hydrocarbons. Therefore, emission factors were picked in order to calculate ROG emissions.

1.1.3.1.2.1 Fuel Assumptions—Completed and Future Construction

Off-road equipment emissions were evaluated assuming that all off-road equipment uses diesel fuel, even though Chevron has indicated that some off-road equipment may use gasoline or other alternative fuel. This approach is conservative from a HRA standpoint because diesel equipment usually contributes higher health risks for exposed populations than equipment using gasoline or other alternative fuel with the same level of activity. This approach may slightly underestimate ROG emissions to the extent that gasoline is used, and underestimate NO_x emissions to the extent that biodiesel is used. This impact is not expected to be significant, as little alternative fueled equipment is reasonably foreseeable.

1.1.3.1.2.2 Off-Road Engine Tier Assumptions—Completed Construction

Comprehensive engine tier information for construction equipment used during completed construction was not available. A review by Chevron of available equipment data for completed construction, which consisted of records for 132⁵ pieces of off-road equipment used for 2008-2009 construction activities, showed that approximately 9% were Tier 1, 42% were Tier 2, 20% were Tier 3, and 29% were not subject to tier standards, either because they were pre-1996 vintage (i.e., built before tier standards came into effect on January 1, 1996), or less than 100 horsepower (Chevron Data Transmittal #36O (Rev #3), 2014). ENVIRON used this information to calculate weighted emission factors for all equipment types. For the purposes of estimating conservative weighted emission factors, ENVIRON utilized fleet mix data for calendar year 2009 from the OFFROAD 2011 model. ENVIRON assigned the weighting associated with the 29% of engines not subject to tier standards to the weighted emission factors for engines with a model year earlier than 1996 in OFFROAD 2011. These calculations assume that the available tier data are representative of the overall distribution of engine tier levels across all construction equipment used during completed construction. They also assume that the same distribution applies to each equipment category (e.g., excavators, bulldozers, cranes, etc.)

1.1.3.1.2.3 Off-Road Engine Tier Assumptions—Future Construction

Future construction emissions were estimated assuming default emission factors and load factors from the CARB OFFROAD 2011 (CARB, 2011a), or from CalEEMod™ default for years 2014, 2015, and 2016 were used. 2014 is a conservative assumption for the predicted start date for future construction, as a

⁵ Approximately 200 pieces of off-road equipment were used during completed construction, so this comprises approximately two-thirds of all equipment used during the completed construction.

later construction start date would result in incrementally cleaner engines, as new engine requirements are phased in.

1.1.3.1.3 On-Site Off-Road Emissions

Table A4.3-CST-6 summarizes both completed and future CAP and GHG emissions from off-road construction equipment.

1.1.3.2 On-Road Mobile Sources

The following sections describe quantification of on-road mobile source emissions emitted on site; later sections will describe on-road mobile source emissions that are emitted off site.

1.1.3.2.1 On-Site On-Road Activity Data

Activity data used to estimate emissions from on-road vehicles include trip counts, trip lengths, vehicle counts, operating schedule, and vehicle type. Table A4.3-CST-7a shows the on-site on-road vehicle activity data for vehicles that travel exclusively on site, provided by Chevron for completed and future construction (Chevron Data Transmittals #20 (Rev #1), 2013; #36O (Rev #3), 2014). There are four general types of vehicles with exclusive on-site on-road activity:

- On-site cars, pickup trucks, and buses that transport workers from the worker parking lot to the construction areas. Emissions were estimated using vehicle counts and operating schedules. Activity data were provided by Chevron and include vehicle count by vehicle type and construction area for each quarter/month of each construction year.⁶ In addition, the number of operating hours per work day was also provided by Chevron (Chevron Data Transmittals #20 (Rev #1), 2013; #36O (Rev #3), 2014). An on-site speed limit of 25 miles per hour (mph) was conservatively assumed to calculate the travel lengths of these vehicles. This is substantially higher than the Facility speed limit of 15 mph and will result in a conservative estimate of travel lengths.⁷
- On-site delivery trucks and flatbeds that transport equipment and materials within the Facility boundary, e.g., from Facility laydown area to the

⁶ For the components of the Modernization Project, activity data were provided for each quarter of each construction year. For the Project Design Features, activity data were provided for each month of each construction year.

⁷ The daily travel length (in miles per day) is calculated by multiplying the assumed travel speed (in mph) by operating hours per work day (in hours per day). Therefore, for a fixed operating hours per work day, the higher the travel speed, the higher the daily travel length. As a result, using 25-mph speed will increase the daily travel length by 67% compared to that calculated using 15-mph speed.

construction areas. Emissions were estimated using vehicle counts and operating schedules. Activity data were provided by Chevron and include vehicle count by vehicle type and construction area for each quarter/month of each construction year.⁸ In addition, the number of operating hours per work day was also provided by Chevron (Chevron Data Transmittals #20 (Rev #1), 2013; #36O (Rev #3), 2014). An on-site speed limit of 25 mph was conservatively assumed to calculate the travel lengths of these vehicles.

- On-site soil hauling trucks (i.e., dump and belly dump trucks) that collect and transport soil within the Facility boundary. Travel paths for these soil hauling vehicles were not well defined, and therefore were modeled over the same spatial areas as off-road equipment at the construction areas.⁹ Emissions were estimated using truck counts and operating schedules. Activity data were provided by Chevron and include vehicle count by vehicle type and construction area for each quarter/month of each construction year.¹⁰ In addition, the number of operating hours per work day was also provided by Chevron (Chevron Data Transmittals #20 (Rev #1), 2013; #36O (Rev #3), 2014).
- Other types of on-site trucks including utility vehicles and vacuum trucks. Travel paths for utility vehicles, and vacuum vehicles were not well defined, and therefore were modeled together with the off-road equipment at the construction areas. Emissions were estimated using truck counts and operating schedules. Activity data were provided by Chevron and include vehicle count by vehicle type and construction area for each quarter/month of each construction year.¹¹ In addition, the number of operating hours per work day was also provided by Chevron (Chevron Data Transmittals #20 (Rev #1), 2013; #36O (Rev #3), 2014).

In addition, there are three general types of vehicles that have both on-site and off-site on-road activity. The on-site portion of the activity was calculated as described below:¹²

⁸ For the components of the Modernization Project, activity data were provided for each quarter of each construction year. For the Project Design Features, activity data were provided for each month of each construction year.

⁹ As a result, these two truck types are shown in Tables 4.3-CST-4a and 4b.

¹⁰ For the components of the Modernization Project, activity data were provided for each quarter of each construction year. For the Project Design Features, activity data were provided for each month of each construction year.

¹¹ For the components of the Modernization Project, activity data were provided for each quarter of each construction year. For the Project Design Features, activity data were provided for each month of each construction year.

¹² Emissions from off-site activity for these vehicles are discussed later in this section.

- Worker commuting vehicles that travel between the Facility boundary and the worker parking lot: Emissions were estimated based on trip counts and trip lengths. The activity data for the on-site worker commuting trips provided by Chevron included one-way vehicle trip counts for the peak day of each quarter/month of each construction year.¹³ The peak day trips were conservatively assumed for every workday of the quarter/month. On-site trip lengths were measured on an aerial photograph based on the trip routes from the Facility boundary to the worker parking lot.
- Delivery trucks that travel between the Facility boundary and the laydown area, which transport construction materials and equipment from off-site vendors to the Facility: Emissions were estimated based on trip counts and trip lengths. The activity for the on-site portion of the delivery trucks provided by Chevron included one-way vehicle trip counts for the peak day of each quarter/month of each construction year.¹⁴ The peak day trips were conservatively assumed for every workday of the quarter/month. Trip lengths were measured on an aerial photograph based on the trip routes from the Facility boundary to the laydown area.¹⁵
- Soil hauling trucks that travel between the Facility boundary and the construction areas, which haul soil from an external source to the Facility or from the Facility to an off-site disposal location: Emissions were estimated based on trip counts and trip lengths. The activity for the on-site portion of the soil hauling trucks were calculated based on the amount of contaminated soil hauled for off-site site disposal and the amount of clean fill imported from off-site location by construction phase (Chevron Data Transmittal #32, 2012) divided by the amount of fill that is carried in a single truck load of 20 tons.¹⁶ On-site trip lengths were measured from an aerial photograph based on the trip routes from the Facility boundary to the construction areas.

¹³ For the construction of components of the Modernization Project, activity data were provided for each quarter of each construction year. For the construction associated with Project Design Features, activity data were provided for each month of each construction year.

¹⁴ For the construction of components of the Modernization Project, activity data were provided for each quarter of each construction year. For the construction associated with Project Design Features, activity data were provided for each month of each construction year.

¹⁵ Modeled travel path for the delivery trucks between facility boundary and the laydown area is different from the actual path. In addition, the modeled path is slightly shorter than the actual path. However the impact to emissions due to this discrepancy is expected to be very small, because the trip length between the facility boundary and the laydown area is a very small percentage of the total trip length of 20 miles.

¹⁶ The only exception is for the existing hydrogen plant demolition/dismantling, for which the number of hauling trips were provided directly by Chevron (Chevron Data Transmittal #360 (Rev #3), 2014).

Table A4.3-CST-7b shows the on-road vehicle activity data for vehicles that travel both on site and off site, provided by Chevron for future and completed construction (Chevron Data Transmittals #20 (Rev #1), 2013; #32, 2012; #360 (Rev #3), 2014).

1.1.3.2.2 On-Road Idling Emissions

On-road construction trucks including all delivery trucks, flatbeds, and soil haul trucks were assumed to idle for 10 minutes at each of four stopping points along their respective on-site travel routes. Specifically, the delivery trucks that travel both on site and off site were assumed to idle at Facility Gate 31 when entering the Facility; at the entrance to the Facility laydown area; at the exit of the laydown area; and finally at Facility Gate 31 when leaving the Facility. The delivery trucks that travel exclusively on site were assumed to idle at the Facility laydown area; at the staging area of each construction area; at the staging area again; and finally at the Facility laydown area. The soil haul trucks were assumed to idle at Facility Gate 31 when entering the Facility; at the staging area of each construction area; at the staging area again; and finally at Facility Gate 31 when leaving the facility.

This assumption of idling for 10 minutes doubles the maximum allowable¹⁷ idling scenario under CARB's Heavy-Duty Vehicle Idling Emission Reduction Program¹⁸ requirement. This method allows for the exceptions to the idling limit under CARB's rules, such as for actively moving lines. This approach will also yield conservative results as it is unlikely that a construction truck will idle at all four points mentioned above during a round trip.

1.1.3.2.3 On-Site On-Road Emission Factors (Completed and Future Construction)

Table A4.3-CST-8 shows the fleet-mix and fuel-mix assumed for on-road vehicle emission calculations. The emission factors for on-road vehicles were obtained from EMFAC2011. Specifically, the 2008-2016 annual emission rates for EMFAC vehicle classes including Light Duty Automobile, Light Duty Truck 1, Light Duty Truck 2, all other buses, Light Heavy-duty Truck 1, Light Heavy-duty Truck 2, Medium Heavy-duty Truck, and Heavy Heavy-duty Truck were downloaded for Contra Costa County. EMFAC2011 includes emission factors for NO_x, PM₁₀, PM_{2.5},

¹⁷ Exceptions to the idling rule are detailed in 13 CCR Title 13, Chapter 10 Section 2485(d), and include but are not limited to idling periods when: the vehicle is queuing at a distance greater than 100 feet from any zoned residential area with at least one residential unit; the vehicle must remain motionless due to official traffic signals or traffic/weather conditions beyond the control of the driver; and when buses have passengers onboard.

¹⁸ The program requirement is available online at: <http://www.arb.ca.gov/msprog/truck-idling/truck-idling.htm>.

ROG, TOG¹⁹, CO, CH₄, N₂O, and CO₂. All buses, delivery trucks, flatbeds and soil hauling trucks were conservatively assumed to be diesel-fueled vehicles. In addition, all on-site cars were assumed to be gasoline vehicles. All the other vehicles including on-site pickups and worker commuting vehicles used EMFAC2011 default fleet fuel mix. To reflect the variability of travel speeds anticipated, “All Speeds” option was chosen in EMFAC2011 to estimate emission factors. Emission factors for years 2008 and 2009 were used for completed construction. Emission factors for years 2014 and 2015 were used for future construction except for the existing hydrogen plant dismantling.²⁰ According to Chevron, the existing hydrogen plant dismantling will occur after the new hydrogen plant starts to operate (Chevron Data Transmittal #360 (Rev #3), 2014). Therefore, emission factors for year 2016 were used for existing hydrogen plant dismantling.

Tables A4.3-CST-9a and 9b summarize the emission factors used for on-road vehicles in this analysis.

1.1.3.2.4 On-Site On-Road Emissions

Table A4.3-CST-10 summarizes both completed and future CAP and GHG emissions from on-road mobile source emissions, from both on-site and off-site travel.

1.1.3.3 Paving and Architectural Coating

According to Chevron there will be approximately 7.5 acres of new paving at the new Hydrogen Plant, and 1.4 acres of new paving at the Sulfur Recovery Unit to complete construction of the Modernization Project (Chevron Data Transmittal #10, 2011). In addition, minimal touch-up painting is expected for the equipment, piping and structural steel (which come to the Facility pre-painted), if any paint damage occurs during installation. Emissions from both paving and architectural coating were included in the emission inventory for future construction; however, no paving or coating was associated with completed construction. Table A4.3-CST-3c shows the calculation methodology for emissions from paving and coating.

¹⁹ The TOG class includes all organic gases emitted into the atmosphere. The ROG class is same as the EPA’s volatile organic compounds definition, and does not contain compounds that are exempt from regulation. Thus, TOG may contain more hydrocarbons than ROG from the same source.

²⁰ Chevron Data Transmittal #360 (Rev#3), 2014 provides equipment data for eight consecutive quarters. Because the exact start date of future construction is uncertain, the emissions analysis conservatively uses emission factors for 2014 for the first four quarters of construction, and 2015 emission factors for the last four quarters of construction.

1.1.3.3.1 Paving/Coating Activity Data

The number of acres to be paved and the gallons of paint to be used for architectural coating were provided by Chevron (Chevron Data Transmittal #10, 2011). Table A4.3-CST-11 shows the activity data used for the emission estimation for paving and architectural coating.

1.1.3.3.2 Paving/Coating Emission Factors

CalEEMod™ default emission factors for paving and non-residential painting/coating were used. Table A4.3-CST-11 presents the calculated emissions for paving and architectural coating.

1.1.3.3.3 Paving/Coating Emissions

Table A4.3-CST-11 summarizes ROG emissions from paving and coating activities associated with future construction.

Table A4.3-CST-12 summarizes total CAP and GHG emissions during completed and future construction, both on site and off site.

1.1.3.4 On-Site Fugitive Dust Emissions

For both completed and future construction, fugitive dust emissions associated with material movement were estimated for construction grading and truck loading based on the given equipment types and soil movement information, consistent with the CalEEMod™ methodology, as described in Table A4.3-CST-3b. The CalEEMod™ methodology uses emissions factors described in EPA AP-42 and are described in Table A4.3-CST-3b. Similarly, the fugitive dust emissions from mobile sources driving on paved roads were calculated for on-site and off-site vehicles using the CalEEMod™ methodology described in EPA AP-42 and presented in Table A4.3-CST-3b.

Table A4.3-CST-13a, b, and c summarize on-site and off-site fugitive dust emissions during completed and future construction by source category. Table A4.3-CST-14 summarizes total fugitive dust emissions during completed and future construction.

1.1.4 Off-Site Construction Activity: Emission Sources

1.1.4.1 On-Road Mobile Sources

1.1.4.1.1 Off-Site On-Road Activity Data

There are three general types of vehicles with off-site on-road activity:

- Delivery trucks that transport construction materials and equipment from off-site vendors to the Facility: Emissions were estimated based on trip counts

and trip lengths. The activity data provided by Chevron included one-way vehicle trip counts for the peak day of each quarter/month of each construction year.²¹ The peak day trips were conservatively assumed for every workday of the quarter/month. Trip lengths were calculated by subtracting the on-site portion of the delivery truck trip routes from the default one-way total trip length of 20 miles.

- Soil hauling trucks that transport soil from an external source to the Facility or from the Facility to an off-site disposal location: Emissions were estimated based on trip counts and trip lengths. The activity data were calculated based on the amount of contaminated soil hauled for off-site site disposal and the amount of clean fill imported from off-site location by construction phase (Chevron Data Transmittal #32, 2012) divided by the amount of fill that is carried in a single truck load of 20 tons.²² Trip lengths were calculated by subtracting the on-site portion of the delivery truck trip routes from the default one-way total trip length of 20 miles.
- Worker commuting vehicles travel from off site to the Facility: Emissions were estimated based on trip counts and trip lengths. The activity data provided by Chevron included one-way vehicle trip counts for the peak day of each quarter/month of each construction year.²³ The peak day trips were conservatively assumed for every workday of the quarter/month. Trip lengths were calculated by subtracting the on-site portion of the delivery truck trip routes from the one-way total trip length of 12.4 miles.

Table A4.3-CST-7b shows the activity data for off-site on-road construction delivery trucks, soil hauling trucks, and worker commuting vehicles provided by Chevron for future and completed construction.

1.1.4.1.2 Off-Site On-Road Emission Factors

Because the vehicles that travel off site also travel on site, the emission factor values and assumptions used for the on-site on-road mobile source emissions from these vehicles (shown in Tables 4.3-CST-9a and 9b) were also used for their off-site on-road mobile source emissions.

²¹ For the components of the Modernization Project, activity data were provided for each quarter of each construction year. For the Project Design Features, activity data were provided for each month of each construction year.

²² The only exception is for the existing hydrogen plant demolition/dismantling, the number of hauling trips were provided directly by Chevron (Chevron Data Transmittal #36O (Rev #3), 2014).

²³ For the construction of components of the Modernization Project, activity data were provided for each quarter of each construction year. For the construction associated with Project Design Features, activity data were provided for each month of each construction year.

1.1.4.2 Off-Site Fugitive Dust Emissions

As mentioned above, the fugitive dust emissions from mobile sources driving on paved roads were calculated for both on-site and off-site vehicles. The emission factors were calculated using the same factors used in CalEEMod from EPA AP-42 and are described in Table A4.3-CST-3b. Table A4.3-CST-14 summarizes total fugitive dust emissions during completed and future construction.

1.1.5 Total Construction CAP and GHG Emissions

Table A4.3-CST-12 summarizes construction CAP and GHG emissions by year for completed construction (2008-2009), for future construction (2014-2016). It also shows the calculated average daily CAP emission rates for future construction only, and for the sum of completed and future construction activity.

1.2 CONSTRUCTION TOXIC AIR CONTAMINANT EMISSIONS

1.2.1 Source Identification, Physical Scope and Temporal Scenarios for Construction Emissions

This section discusses the emissions estimation of TACs associated with the construction of the Modernization Project. Emissions of TACs are estimated to use in a HRA to assess the health impacts of the construction. This is further described in *Appendix 4.3-CHRA*. Table A4.3-CST-15 summarizes the scope of the TAC emission inventory, the details for which are presented in the subsections below.

There are two general types of construction TAC emission sources:

- Off-road construction equipment , and
- On-road mobile sources.

It was assumed that no TAC emissions are generated from fugitive dust, paving or architectural coating.

1.2.1.1 Physical Domain for TAC Emissions Inventory

Only emissions that are used in the HRA are estimated. Because of this, while the physical domain for the TAC emissions inventory includes all on-site construction TAC sources, the physical extent of off-site TAC emissions included for the HRA is smaller than the extent of off-site emissions included for the criteria pollutant inventory.

As further discussed in *Appendix 4.3-CHRA*, the number of Modernization Project-related construction trucks and worker commuting vehicles on highways is very small relative to highway background traffic; because of this, their

emissions will not have a significant health impact on the sensitive population located along the highways. Accordingly, receptors that are exposed only due to their proximity to a highway that may be used by trucks going to and from the Chevron construction sites were not included in the HRA, and thus the portion of emissions from worker commuting vehicles and construction trucks that occurs on the highways were also not included in the TAC inventory used in the HRA. The TAC inventory does include Modernization Project-related truck and worker commuting emissions associated with travel along Richmond Parkway, Castro Street, and on the highway on- and off-ramps.

1.2.1.2 Temporal Scenarios: Completed Construction and Future Construction

As described in the criteria pollutant emissions section, emission inventories were developed for both completed construction (i.e., completed in 2008-2009) and future construction (2014-2016).

1.2.2 Identification of TACs Generated by the Modernization Project

The TAC emissions inventory includes chemicals emitted from sources that are included for consideration in HRAs consistent with Bay Area Air Quality Management District (BAAQMD) Regulation 2, Rule 5. The TAC emissions inventory for construction is based on diesel particulate matter (DPM) emissions from the off-road construction equipment and the diesel on-road vehicles, and gasoline TOGs from the gasoline on-road vehicles. $PM_{2.5}$ concentrations were also calculated as part of the HRA for comparison to BAAQMD CEQA thresholds for ambient concentrations of $PM_{2.5}$.

Diesel exhaust, a complex mixture that includes hundreds of individual constituents (OEHHA, 1998), is identified by the State of California as a known carcinogen (Cal/EPA, 2011). Under California regulatory guidelines, DPM is used as a surrogate measure of carcinogen exposure for the mixture of chemicals that make up diesel exhaust as a whole. The California Environmental Protection Agency (Cal/EPA) and other proponents of using the surrogate approach to quantifying cancer risks associated with the diesel mixture indicate that this method is preferred over the use of a component-based approach. A component-based approach involves estimating risks for each of the individual components of a mixture. Critics of the component-based approach believe it will underestimate the risks associated with diesel as a whole mixture because the identity of all chemicals in the mixture may not be known and/or exposure and health effects information for all chemicals identified within the mixture may not be available. Furthermore, Cal/EPA has concluded that “potential cancer risk from inhalation exposure to whole diesel exhaust will outweigh the multi-

pathway cancer risk from the speciated components” (OEHHA, 2003). The PM_{10} emissions from the off-road construction equipment and the diesel on-road vehicles were assumed to be equivalent to DPM in the emissions estimation.

TACs from exhaust and evaporative TOGs emissions from gasoline-fueled vehicles were evaluated based on the speciation profiles presented in the BAAQMD guidelines, which include: acetaldehyde, acrolein, benzene, 1,3-butadiene, ethylbenzene, formaldehyde, hexane, methanol, methyl ethyl ketone, naphthalene, propylene, styrene, toluene, and xylenes (BAAQMD, 2012).

1.2.3 TAC Emissions from On-Site Construction Sources

On-site construction sources of TAC emissions are diesel off-road construction equipment, and diesel and gasoline on-road vehicles. These sources do not have emission factors specifically for DPM in their respective emission factor databases (OFFROAD and EMFAC). DPM is a subset of the PM_{10} from diesel exhaust. PM_{10} emissions from on-site diesel off-road equipment and on-road vehicles that were calculated for the CAP inventory for on-site construction sources were used as conservative, surrogate estimates for DPM. The PM_{10} emissions were also used as surrogates for $PM_{2.5}$, when a $PM_{2.5}$ emission factor was not available. Exhaust and evaporative TOG emissions from on-site gasoline-fueled vehicles were estimated using EMFAC2011 TOG emission factors. Refer to the CAP on-site construction inventory section and Tables 4.3-CST-4a, 4b, 5a, 5b, 7a, 7b, 8, 9a, and 9b for details on the emission factors, activity data and assumptions used to estimate PM_{10} , $PM_{2.5}$, and TOG.²⁴

Table A4.3-CST-16 summarizes total off-road construction equipment DPM and $PM_{2.5}$. As discussed earlier, the same emission factor was used to estimate both pollutants; hence, the estimates are numerically equal. Table A4.3-CST-17 summarizes DPM and $PM_{2.5}$ for all on-road vehicles, and TOG emissions from gasoline on-road vehicles for both on-site and off-site activities.

1.2.4 TAC Emissions from Off-Site Construction Sources

Off-site construction sources of TAC emissions are the same as the off-site sources of CAP emissions discussed in the CAP inventory section: delivery trucks, soil hauling trucks, and worker commuting vehicles. As described previously for the on-site construction sources, PM_{10} emissions from on-road vehicles that were

²⁴ Modeled travel path for the delivery trucks between facility boundary and the laydown area is different from the actual path. In addition, the modeled path is slightly shorter than the actual path. Therefore the TAC emissions were slightly underestimated due to this discrepancy. However, the modeled travel path is much closer to the maximally exposed individual sensitive receptor location than the actual path. Therefore, the impact of this discrepancy is minimal.

calculated for the CAP inventory for off-site sources were used as surrogates for DPM and PM_{2.5}. Exhaust and evaporative TOG emissions from gasoline-fueled vehicles are based on EMFAC2011 TOG emission factors. However, for the HRA, only a subset of the off-site emissions estimated for the CAP inventory were included in the TAC inventory. As described previously, for emissions estimation and dispersion modeling of TACs, off-site on-road mobile source emissions were modeled along the off-site segments of Richmond Parkway, Castro Street, and the highway ramps only.

Table A4.3-CST-17 summarizes DPM and PM_{2.5} for all on-road vehicles, and TOG emissions from gasoline on-road vehicles for both on-site and off-site activities.

1.2.5 Calculation of Maximum Hourly Emission Rates for Acute Non-Cancer Hazard Analysis

Maximum hourly TAC emissions were also calculated for acute non-cancer hazard evaluation. Because of the uncertainty of source test methodology for the diesel exhaust speciation, especially for the measurement of acrolein, maximum hourly TAC emissions for gasoline TOGs were included in this estimation.²⁵ As discussed above, gasoline TOGs are generated by on-site and off-site worker trips. Because the activity data for the worker trips provided by Chevron included one-way vehicle trip counts or trip count for the peak day of each quarter/month of each construction year,²⁶ peak day gasoline TOG emissions were calculated for both on-site and off-site worker trips for each quarter of each construction year. Then maximum hourly emissions were calculated by dividing the peak day emissions by 10 hours of construction per day. These peak hour emissions were then used in air dispersion modeling. More details on emissions by modeled source group are provided in *Appendix 4.3-CHRA*.

1.2.6 Conversion of Emission Rate Units for Use in Air Dispersion Modeling

For air dispersion modeling, emissions need to be spatially allocated based on where and how they will be emitted. More details on emissions apportionment is provided in *Appendix 4.3-CHRA*.

²⁵ This methodology was approved by the BAAQMD on August 12, 2013.

²⁶ For the construction of components of the Modernization Project, activity data were provided for each quarter of each construction year. For the construction associated with Project Design Features, activity data were provided for each month of each construction year.

1.3 CONSTRUCTION CRITERIA POLLUTANT AND TOXIC AIR CONTAMINANT EMISSIONS FOR MODERNIZATION PROJECT MITIGATION MEASURES

Chevron has proposed potential construction of a 2 megawatts (mW) ground-mounted photovoltaic solar facility on approximately 13 acres of Chevron property, located adjacent to Castro Street as a greenhouse gas mitigation measure (Chevron Data Transmittal #43, 2013). In addition, Chevron may install up to 14 tank domes to off-site any potential Modernization Project ROG emissions increases. The section below discusses methodology used to quantify emissions from construction of these mitigation measures.

1.3.1 Emissions from Construction of the 2 mW Solar Facility

Activity data provided by Chevron were used to calculate emissions from off-road construction equipment and on-road mobiles for the construction of the 2 mW solar facility (Chevron Data Transmittal #69 (Rev #1), 2014). Methodology used for emissions calculation was consistent with the methodology described in *Section 1.1* and *1.2*. It was conservatively assumed that the construction of the solar facility start in January of 2014. Tables 4.3-CST-18 and 4.3-CST-19 present the criteria pollutants, GHG, and TAC emissions from construction of the solar facility respectively.

1.3.2 Emissions from Construction of 14 Tank Domes

Emissions from construction of the 14 tank domes were assumed to be missions from installation of the one tank dome as one of the Modernization Project Design Features times 14 (Chevron Data Transmittal #36O (Rev #3), 2014). This approach is conservative for two reasons: (1) The Project Design Feature was assumed to be constructed in 2014, while the first of the 14 tanks will be constructed in 2016; and (2) the construction schedule of the tank domes is one at a time and two per year (Chevron Data Transmittal #36O (Rev #3), 2014). Therefore it will take approximately 7 years to construct all 14 tank domes. This approach however did not assume cleaner construction equipment and therefore resulted in conservative emissions. Tables 4.3-CST-20 and 4.3-CST-21 present the criteria pollutants, GHG and TAC emissions from construction of the 14 tank domes respectively.

Table A4.3-CST-1
Modernization Project Components
Chevron Modernization Project
Richmond, California

	Project Component	Construction Complete	Construction Remaining	Equipment Dimensions
Hydrogen Plant Replacement Description				
Replace Existing Hydrogen Plant with a More Efficient Hydrogen Plant That Produces More and Higher Quality ("more pure") Hydrogen	1. Hydrogen Recovery Vessels	Vessels are set in place. Piping, instrumentation, and electrical wiring have been procured and are on site.	Abovegrade ancillary piping, instrumentation, electrical wiring.	60 feet high
	2. Train 1 Steam Reformer Furnace	Furnace is set in place. Piping, instrumentation, and electrical wiring have been procured and are on site.	Abovegrade ancillary piping, instrumentation, electrical wiring.	162 feet high
	3. Train 2 Steam Reformer Furnace	Furnace is set in place. Piping, instrumentation, and electrical wiring have been procured and are on site.	Abovegrade ancillary piping, instrumentation, electrical wiring.	162 feet high
	4. Pressure Swing Adsorption Recovery Unit	Unit is set in place. Piping, instrumentation, and electrical wiring have been procured and are on site.	Abovegrade ancillary piping, instrumentation, electrical wiring.	60 feet high
	5. Flare	Foundation has been installed. The flare, piping, instrumentation, and electrical wiring have been procured and are on site.	Set flare in place; install ancillary piping, instrumentation, and electrical wiring (all above grade).	195 feet high
	6. Cooling Water Tower	Foundation has been installed. The cooling water tower, piping, instrumentation, and electrical wiring have been procured and are on site.	Set cooling water tower in place; install ancillary piping, instrumentation, and electrical wiring (all above grade).	43 feet high
	7. Steam Turbine Generator (provides electric power to the hydrogen plant)	None. The generator, piping, instrumentation, and electrical wiring have been procured and are on site.	Foundation completion. Set equipment in place. Abovegrade piping, instrumentation, and electrical wiring.	17 mW net output
	8. Upgrade Hydrogen Booster Compressors	None. Equipment to upgrade the compressors has been procured and is on site.	Abovegrade modifications to compressors to process higher pressures from new hydrogen plant.	No change in dimensions. Thicker wall to handle higher hydrogen pressure.
	9. Upgrade Richmond Lube Oil Plant Area Compressors	None. Equipment to upgrade the compressors has been procured and is on site.	Abovegrade modifications to compressors to process higher-purity, lower-density hydrogen than present.	No change in dimensions. Thicker wall to handle higher hydrogen pressure.
	10. Upgrade Distillation and Reforming Area Compressors	None. Equipment to upgrade the compressors has been procured and is on site.	Abovegrade modifications to compressors to process higher-purity, lower-density hydrogen than present.	Internal changes only. No change in dimensions.
	11. Upgrade Isomax Area Compressors	35% Complete (FCC FHT area).	Complete turbine and compressor upgrades in remainder of facility. Abovegrade and belowgrade modifications to process higher-purity, lower-density hydrogen than present.	No change in dimensions rotating equipment. New 40-foot-tall structure for lubrication of machinery.
	12. Process Piping And Fittings	Small portion of process piping and fittings. Piping and fittings have been procured and are on site.	Majority of process piping and fittings.	Various lengths and diameters
	13. New Control Room	Control Room building has been constructed.	Interior walls, utility connections, electrical wiring, finish work (walls, floors, décor).	9,450 square feet
	14. Modify/Upgrade Electrical and Communications Infrastructure	None. Transmitters have been procured and are on site.	Smart transmitters for process monitoring.	N/A
Reverse Osmosis Plant Expansion	15. Two Reverse Osmosis Trains, One Pump, One Water Storage Tank, and Piping	None	All	Reverse osmosis trains: 500 gpm each Tank: 20,000 barrels Piping: 1,000 feet
Boiler Feed Water Optimization and Condensate Recovery	16. Piping and Two Pumps	25%	75% – piping installation	Pumps:500 gpm Piping: 2,500 feet
Decommission Existing Hydrogen Plant	17. Dismantle Existing Hydrogen Plant	None	All	N/A
Sulfur Removal Improvements				
Modify and Install Equipment to Remove and Recover Additional Quantities Of Sulfur From the Sour Gas System.	18. Upgrade Sulfur Recovery Units	All equipment has been procured and is on site. Minor process piping and oxygen skid are installed.	Two heat exchanger modifications per unit. Additional piping upgrades and furnace modifications for oxygen injection per unit. Installation of new emissions control and containment equipment (e.g., wet electrostatic precipitator).	475 x 150 feet (existing—no change proposed)
	19. Upgrade Sour Water Concentrator	100%	None	400 gpm
FCC FHT – Modifications	20. Add, Modify, or Replace Four Sumps, Two Vessels, Two Heat Exchanges, and Process Piping to Improve FCC FHT Reliability	100%	None	No change in dimensions
FCC FHT – Feed Rate Increase	21. Add, Replace, or Modify Seven Heat Exchangers, Modify or Replace Nine Pumps, and Modify One Distillation Column Internal Components	None. Heat exchangers and pumps are still in the design phase and have not been procured.	Complete design and procurement of new, replacement, and modified equipment. Install new heat exchangers and modify existing heat exchangers. Install new pumps, and modify existing pumps. Make modifications to distillation column internal components (trays).	N/A; design incomplete
	22. Process Piping and Fittings	None. Piping and fittings have not been procured.	Install process piping and fittings.	N/A; design incomplete
Sulfur Removal – Amine Contractor and Regenerator	23. Recycle Hydrogen Amine Contactor	None. Piping and instrumentation has been procured and are on site.	Set contactor in place; connect ancillary piping, instrumentation, and electrical wiring.	100 feet high 0.3 MM standard cubic feet per minute
	24. Amine Regenerator	None. Piping and instrumentation has been procured and are on site.	Set regenerator in place; connect ancillary piping, instrumentation, and electrical wiring.	120 feet high
	25. Rich Amine Storage Tank	None. Piping, instrumentation and wiring has been procured and is on site.	Set tank in place; connect ancillary piping, instrumentation, and electrical wiring (all above grade).	35 feet diameter x 24 feet high
	26. Fresh Amine Storage Tank	None. Piping and instrumentation has been procured and is on site.	Set tank in place; connect ancillary piping, instrumentation, and electrical wiring (all above grade).	25 feet diameter x 20 feet high
	27. Fresh Caustic Storage Tank	None. Piping and instrumentation has been procured and is on site.	Set tank in place; connect ancillary piping, instrumentation, and electrical wiring (all above grade).	40 feet high
	28. Spent Caustic Storage Tank	None. Piping and instrumentation has been procured and is on site.	Set tank in place; connect ancillary piping, instrumentation, and electrical wiring (all above grade).	40 feet high
	29. Acid Gas Scrubber	None. Scrubber, piping, and instrumentation have been procured and are on site.	Set scrubber in place; connect ancillary piping, instrumentation, and electrical wiring (all above grade).	70 feet high
	30. Liquid Oxygen Storage Tank and Vaporizer	Liquid oxygen tanks and vaporizer have been set in place. Piping and connections have been procured and are on site.	Abovegrade piping and connections.	50 feet high
	31. Process Piping and Fittings	A small portion (5%) of required piping and fittings has been installed. The remainder of piping and fittings has been procured and are on site.	Install remainder of piping and fittings.	D: 2–16 inches L: (see columns to left)
	32. New Power Recovery Turbine	None on mechanical equipment. Foundations for new equipment complete. 10% complete overall.	Complete piping and install mechanical equipment and structural components.	920 recovered horsepower
	33. Low Nitrogen Oxide Burners	None installed. Equipment procured only.	Modify furnaces in TKN and Poly units to handle new burners. Install filters to and equipment.	Replacement of burners: 3 feet x 2 feet per burner
	34. New Truck Loading/ Unloading Rack for Bisulfite, Caustic, and Amine	None. Loading arms and ancillary piping have been procured and are on site.	Complete foundations and install new loading arms and ancillary piping.	20-foot-high arm
Related Piping and Other Ancillary Equipment	35. Off-Plot Interconnecting Piping and Pipe Racks	P and O racks are 100% complete. W, Q, and V racks are 50% complete. Structural steel and piping has been procured and is on site. Approximately 7,000 ft of piping for	Remainder of W, Q, and V racks (above ground with some minor soil excavation for steel support footings. Approximately 41,000 linear feet of piping for P, O, U, V, and W	D: 2–16 inches L: (see columns to left)
Project Design Features				
	36. Marin Clean Energy Participation	N/A	N/A	N/A
	37. Marine Engines Upgrades	None	Upgrade main ship and auxiliary engines to IMO Tier 3 standards.	N/A
	38. LED Lighting	None	Replace existing lighting with LED lights.	N/A
	39. Water Reuse: South Isomax	None	Heat exchanger, process piping, and fittings.	N/A; design incomplete
	40. Water Reuse: Distillation and Reforming	None	Two electric pumps, process piping, and fittings.	N/A; design incomplete
	41. Storage Tank Dome	None	Installation of spherical, geodesic tank dome on T-1491.	D: 90 ft
	42. FCC Cooling Water Tower Motor Upgrade	None	Replace existing constant speed motors and gearbox drive system with adjustable speed direct drive motors and drive system.	N/A; design incomplete

Chevron Modernization Project
Richmond, California

Source Category	Examples	CAP Emitted with CEQA Mass Thresholds GHG Emitted	Emitting Location
Off-road construction equipment (diesel engines)	excavators, bulldozers, cranes	NOx, PM ₁₀ , PM _{2.5} , ROG, N ₂ O, CH ₄ , CO ₂	on site
On-road mobile sources (diesel and gasoline engines)	trucks, cars, pickups, and buses	NOx, PM ₁₀ , PM _{2.5} , ROG, N ₂ O, CH ₄ , CO ₂	on site and off site
Architectural coatings and paving	paints, asphalt	ROG	on site
Fugitive dust	soil movement, mobile source movement	PM ₁₀ , PM _{2.5}	on site and off site

Abbreviations:

CAP = criteria air pollutants
 CEQA = California Environmental Quality Act
 GHG = greenhouse gas
 NOx = oxides of nitrogen
 PM₁₀ = respirable particulates (less than 10 microns in diameter)
 PM_{2.5} = fine particulates (less than 2.5 microns in diameter)
 ROG = reactive organic gas

Table A4.3-CST-3a
Methodology of Emissions Calculations Associated with Construction Activities - Exhaust, Brakewear and Tirewear Emissions
Chevron Modernization Project
Richmond, California

Source	Emission Category	Methodology and Formula	Reference
Off-Road Equipment ¹	Exhaust	$E_c = \sum_i (EF_{Ci} * HP_i * LF_i * Hr_i * C11 * C)$	ARB/USEPA Engine Standards , and ARB In-use Off-road Equipment Inventory Model
On-Road Mobile Sources ²	Exhaust - Running	$E_R = \sum_i (EF_{Ri} * VMT_i * C)$, $VMT_i = \text{Trip Length}_i * \text{Trip Number}_i$ where	EMFAC2011
	Brakewear and Tirewear - Running	$E_w = \sum_i (EF_{wi} * VMT_i * C)$, where $VMT_i = \text{Trip Length}_i * \text{Trip Number}_i$	EMFAC2011
	Exhaust - Startup	$E_s = \sum_i (EF_{Si} * \text{Trip Number}_i)$	EMFAC2011
	Exhaust - Idling	$E_i = \sum_i (EF_{Ii} * \text{Trip Number}_i)$	EMFAC2011

Notes:

1. E_c : off-road equipment exhaust emissions (lb).

EF_{Ci} : emission factor (g/hp-hr) for equipment i.

a. Completed construction: Weighted EF based on engine log for completed construction. See Transmittal #360.

b. Future construction: ARB In-use Off-road Equipment Inventory Model default EF.

HP_i : equipment horsepower for equipment i (hp). CalEEModTM default equipment horsepower that was confirmed by Chevron.

LF_i : equipment load factor for equipment i (unitless). ARB In-use Off-road Equipment Inventory Model default equipment load factor.

Hr_i : equipment hours for equipment i (hr). Provided by Chevron. See Transmittals #20 and #360.

C: unit conversion factor (lb/g).

2. On-road mobile sources include all construction-related onsite and offsite trips. Emissions associated with mobile sources were calculated using the following formulas:

E_R : running exhaust emissions (lb).

EF_{Ri} : running emission factor (g/mile) for vehicle i. From EMFAC2011 online "Emission Rates Database", for all model years of vehicle classes LHD1, LHD2, T6, T7, LDA, LDT1, LDT2, and All Other Buses in Contra Costa County in 2008, 2009, 2014, 2015, and 2016.

Assumed "AllSpeeds"

VMT_i : vehicle miles traveled for vehicle i

The calculation involves the following data and assumptions:

(1) 1) All soil hauling trucks are heavy-heavy duty trucks (EMFAC Category T7). Construction delivery trucks and flatbeds are a mix of LHD1, LHD2, T6, and T7 based on data provided by Chevron. See Transmittals #20 and #360.

(2) Onsite cars are LDA.

(3) Onsite pickups are LDT1.

(4) Onsite buses are All Other Buses.

(5) Worker commuting vehicles are a mix of LDA (50%), LDT1 (25%), and LDT2 (25%). The split is based on CalEEModTM default assumptions for construction workers.

(7) Trip Length: The one-way trip length depends on which construction area the trip serves. For the offsite portion of the trip, a one-way length used for local risk impacts analysis is assumed to be the length of the roadway to the highway ramps, and the one-way length used for criteria pollutant impact analysis is assumed to be 20 miles for trucks and 12.4 miles for worker trips, the CalEEModTM default.

Trip Number: Chevron provided vehicle trip data.

E_w : running brakewear and tirewear emissions (lb).

EF_{wi} : brakewear and tirewear emission factor (g/mile) for vehicle i. From EMFAC2011 online "Emission Rates Database", for all model years of vehicle classes LHD1, LHD2, T6, T7, LDA, LDT1, LDT2, and All Other Buses in Contra Costa County in 2008, 2009, 2014, 2015, and 2016.

Assumed "AllSpeeds"

VMT_i : vehicle miles traveled for vehicle i

The calculation involves the same data and assumptions as used in E_R calculations.

E_s : vehicle startup emissions (lb).

EF_{Si} : vehicle startup emission factor (g/trip) for vehicle i. From EMFAC2011, which reports startup emissions in tons/day. The emission factor (g/trip) is calculated to by dividing the emissions by the total number of trips per day for each vehicle category.

E_i : vehicle idling emissions (lb).

EF_{Ii} : vehicle idling emission factor (g/trip) for vehicle i. From EMFAC2011, which reports emission factors in g/hr-vehicle. The emission factor is calculated to assume an average idling time per trip. It was assumed that a 10-minute idling happens for a one-way trip, at each potential idling point.

C: unit conversion factor (lb/g).

Abbreviations:

ARB: California Air Resources Board

CalEEModTM: California Emissions Estimator Model

DPF: Diesel Particulate Filter

EF: Emission Factor

EMFAC: Emission FACTor Model

g: gram

HP: Horsepower

lb: pound

LF: Load Factor

mi: mile

min: minute

USEPA: United States Environmental Protection Agency

VMT: vehicle miles traveled

Table A4.3-CST-3b
Methodology of Emissions Calculations Associated with Construction Activities - Fugitive Dust Emissions
Chevron Modernization Project
Richmond, California

Source	Emission Category	Methodology and Formula	Reference
Material Movement	Grading ¹	$E_{PM10} = \Sigma(EF_{PM10} * VMT)$, where $EF_{PM10} = 0.051 * (S)^{2.0} * F_{PM10}$	USEPA AP-42
		$E_{PM2.5} = \Sigma(EF_{PM2.5} * VMT)$, where $EF_{PM2.5} = 0.04 * (S)^{2.5} * F_{PM2.5}$	USEPA AP-42
	Truck Loading ²	$E_{PM10} = \Sigma(EF_{PM10} * TP)$, where $EF_{PM10} = k_{PM10} * 0.0032 * (U/5)^{1.3} * [1/((M/2)^{1.4})]$	USEPA AP-42
		$E_{PM2.5} = \Sigma(EF_{PM2.5} * TP)$, where $EF_{PM2.5} = k_{PM2.5} * 0.0032 * (U/5)^{1.3} * [1/((M/2)^{1.4})]$	USEPA AP-42
Mobile Source Driving on Paved Road ³		$E_i = \Sigma(EF_{PM10} * VTM)$, where $EF = [k*(sL)*0.91*(W)*1.02][1-P/(4N)]$	USEPA AP-42
		$E_i = \Sigma(EF_{PM2.5} * VTM)$, where $EF = [k*(sL)*0.91*(W)*1.02][1-P/(4N)]$	USEPA AP-42

Notes:

1. Fugitive dust emissions from grading equipment passes are estimated using the methodology described in Section 11.9, Western Surface Coal Mining, of the USEPA AP-42. Ec: off-road equipment exhaust emissions (lb). AP-42 estimates the emission factor of PM₁₀ applying a scaling factor to that of PM₁₅. Similarly, the emission factor of PM_{2.5} is scaled from that of total suspended particulates (TSP). In this table, ENVIRON combined the PM₁₅ /TSP EF calculation and scaling into a single equation for calculating PM₁₀/PM_{2.5}.

EF: emission factor (lb/VMT)

S: mean vehicle speed in mph. AP-42 default of 7.1 mph was used in the absence of project-specific data.

F: PM scaling factor. The AP-42 default value is 0.031 for PM_{2.5} and 0.6 for PM₁₀.

The grading dust emissions were then calculated by multiplying the emission factors with the total vehicle miles traveled (VMT) for the grading equipment (i.e., grader).

$VMT = As/Wb \times 43,560 \text{ (sqft/acre)} / 5,280 \text{ (ft/mile)}$

Where:

As: the acreage of the grading side. The acres is based on the equipment list and days in grading phase according to the anticipated maximum number of acres a given piece of equipment can pass over in an 8-hour workday. ENVIRON uses 0.5 acres/8-hr day for grader as suggested by SCAQMD.

Wb: Blade width of the grading equipment. ENVIRON uses a default blade width of 12 ft based on Caterpillar's 140 Motor Grader.

2. Processes such as truck dumping on the pile or loading out from the pile to a truck with a front-end loader also cause fugitive dust emissions. ENVIRON calculates the truck loading emissions using the methodology described in Section 13.2.4 of USEPA AP-42. As shown in the formula in the table, the emission factor is based on the material moisture content and mean wind speed:

EF: emission factor (lb/ton)

TP: throughput of load and unload material. From Transmittal #32.

k: particle size multiplier. The AP-42 default value for PM₁₀ is 0.35 and that for PM_{2.5} is 0.053.

U: mean wind speed. Project specific mean wind speed of 8.6 mph was used.

M: material moisture content (%). The moisture content of cover (12%) was used in this calculation.

2. ENVIRON calculates the fugitive dust emissions from mobile source driving on paved road using the methodology described in Section 13.2.1 of USEPA AP-42.

EF: emission factor

k: particle size multiplier (lb/VMT). ENVIRON used the PM₁₀ and PM_{2.5} particle size multiplier from Section 13.2.1-1 of USEPA AP-42.

sL: road surface silt loading (g/m²). ENVIRON used 0.2 g/m² (Ubiquitous Baseline) from AP-42.

W: average weight (tons) of the vehicles traveling the road. Based on ARB's EMFAC model.

P: number of "wet" days with at least 0.01 in of precipitation during the averaging period, ENVIRON used 60 days based on climate data from (<http://www.wrcc.dri.edu/>) for Richmond station (047414)

N: number of days in the averaging period. (365 days)

Abbreviations:

ARB: Air Resources Board

EF: Emission Factor

EMFAC: Emissions FACTor model.

g: gram

PM: Particulate Matter

TP: throughput

TSP: Total Suspended Particulates

USEPA: United States Environmental Protection Agency

VMT: vehicle miles traveled

Table A4.3-CST-3c

**Methodology of Emissions Calculations Associated with Construction Activities - Paving and Architectural Coating
Chevron Modernization Project
Richmond, California**

Source	Emission Category	Methodology and Formula	Reference
Paving ^{1,3}	Off-Gas	$E_p = EF_p \times \text{Acreage of Paving}$	CalEEMod TM
Architectural Coating ^{2,3}	Off-Gas	$E_A = EF_A \times \text{Paint Usage}$	CalEEMod TM

Notes:

1. E_p : paving emissions (lb).
 EF_p : emission factor (lb/acre). CalEEModTM default emission factor for paving is 2.62 lb/acre.
2. E_A : architectural coating emissions (lb).
 EF_A : emission factor (lb/gallon). CalEEModTM default emission factor for non-residential painting/coating is EF_A (lb/gal) = $C_{voc}(g/L) / 454(g/lb) \times 3.785(L/Gal)$. The default VOC content of 250 g/L is ARB's statewide limit as indicated in CalEEModTM User's Guide.
3. The number of acres to be paved and the gallons of paint to be used for architectural coating was provided by Chevron.

	Welding Machines	Other General Industrial Equipment	45	0.3417	9	10/25	66/66	30	129

Notes:

1. This table is developed based on the equipment count by equipment type and construction phase for each quarter of the year , provided by Chevron. See Transmittal #20. For equipment quantities and days of operation separated by "/", their order corresponds with each other. For example "10/3" for equipment quantities and "66/66" for days of operation (as seen for dump truck under the hydrogen plant replacement phase) for year 2008, it means 10 pieces of equipment operate for 66 days followed by 3 pieces of equipment operate for another 66 days.
2. CalEEModTM default equipment horsepower was used.
3. Load factor was from the ARB In-Use Off-Road Equipment Emissions Inventory Model.
4. Chevron did not provide the actual days of operation information. It was conservatively assumed that the equipment operates every workday of the quarter when the construction phase happens., except that all construction ceased by September 1, 2009.

Notes:
1. This table is developed based on the equipment count by equipment type and construction phase for each quarter of the year for the Project components and for each month of the year for the Project Design Features (PDFs), provided by Chevron. See Transmittal #360.
2. CalEEModTM default equipment horsepower was used.
3. Load factor was from the ARB In-Use Off-Road Equipment Emissions Inventory Model.
4. Chevron did not provide the actual days of operation information. It was conservatively assumed that the equipment operates every workday of the quarter for the Project components when the construction phase happens. For the PDFs, the by-month construction count was converted to a quarterly equipment count.
5. Transmittal #360 provides equipment data for 8 consecutive quarters. Because the exact start date of future construction is uncertain, the emissions analysis conservatively uses emission factors for 2014 for the first 4 quarters of construction, and 2015 emission factors for the last 4 quarters of construction.
6. According to Chevron, the existing hydrogen plant dismantling will occur after the new hydrogen plant starts to operate.

Notes:

1. Completed construction occurred in years 2008 and 2009.
2. These equipment types were provided in Transmittal #20.
3. The provided equipment types were mapped to the closest equipment types in the ARB In-use Off-road Equipment Inventory Model.
4. Emission factors from the ARB In-use Off-road Equipment Inventory Model for year 2009 were used.
5. Emission factors were a weighted average of Tier 1, Tier 2, Tier 3, and Tier 0 engines based on the engine log in Transmittal #360 and engine tier standard specified in 13 CCR 2423(b)(1). For Tier 0 engines, the emission factors for engines with a model year earlier than 1996 for year 2009 in the ARB In-use Off-road Equipment Inventory Model were weighted because Tier standard was taken effect on January 1, 1996.
6. ROG emission factors were calculated by multiplying the HC emission factors by 1.053/0.984 based on USEPA conversion factor. TOG emission factors were calculated by multiplying the HC emission factors by 1.07/0.984 based on USEPA conversion factor.
7. PM₁₀ emission factor was conservatively used as a surrogate for PM_{2.5} emission factor.
8. CH₄ emission factor is TOG emission factor multiplied by 0.0774.
9. CalEEMod™, 2011.1.

Abbreviations:

ARB: California Air Resources Board
CO: carbon monoxide
CO₂: carbon dioxide
CH₄: methane
g: gram
hp: horsepower
HC: hydrocarbon
hr: hour
N₂O: nitrous oxide
NOx: nitrogen oxides
PM₁₀: coarse particulate matter
PM_{2.5}: fine particulate matter
ROG: reactive organic gas
USEPA: United States Environmental Protection Agency

Notes:
1. Future construction occurred in years 2014-2016.
2. These equipment types were provided in Transmittal #360.
3. The provided equipment types were mapped to the closest equipment types in the ARB In-use Off-road Equipment Inventory Model.
4. Emission factors from the ARB In-use Off-road Equipment Inventory Model were used.
5. ROG emission factors were calculated by multiplying the TOG emission factors by 1.0531-07 based on USEPA conversion factor.
6. PM₁₀ emission factor was conservatively used as a surrogate for PM_{2.5} emission factor.
7. CH₄ emission factor is TOG emission factor multiplied by 0.0774, based on ARB recommendation.
8. CO₂Eq factor is TOG emission factor multiplied by 0.0774, based on ARB recommendation.

Notes:

1. This table is developed based on the vehicle type and schedule information provided by Chevron. See Transmittals #20 and #36O.
2. As shown in Table 4.3-CST-3a, Vehicle Miles Travelled (VMT) is needed to calculate onroad vehicle emissions. Since Chevron provided the hours of daily use, it was assumed that the VMT per vehicle per day can be calculated by multiplying the daily hours by the onroad vehicle speed (miles/hour). An onsite vehicle speed of 25 miles/hour was used for the calculation.
3. As specified in Table 4.3-CST-3a, emission factors of onroad vehicles were derived from EMFAC2011.
- The calculation involves the following data and assumptions:
- (1) Consturction delivery trucks, and flatbeds are a mix of LHD1, LHD2, T6, and T7 based on data provided by Chevron. See Transmittals #20 and #36O.
- (2) Onsite cars are LDA.
- (3) Onsite pickups are LDT1.
- (4) Onsite buses are All Other Buses.
4. Since emission factors derived from EMFAC2011 vary by construction year, due to fleet renovation, year of construction will have an impact on the onroad vehicle emissions. Therefore total number of working days per construction year are presented in this table.

Abbreviations:

ARB: California Air Resources Board
EMFAC: EMission FACtor Model
VMT: Vehicles Mile Travelled

			Worker	Worker Parking Lot	113,800	0
	2016	Offsite	Soil Hauling Truck	Gate 31	600	10
			Worker	Worker Parking Lot	5,220	0
		Onsite	Soil Hauling Truck	Hydrogen Plant	600	10
			Worker	Worker Parking Lot	5,220	0

Notes:

1. This table is developed based on the vehicle type and schedule information provided by Chevron. See Transmittals #20, #32, and #36O.
2. As specified in Table 4.3-CST-7b emission factors of onroad vehicles were derived from EMFAC2011. The calculation involves the following data and assumptions:
 (1) All soil hauling trucks are heavy-heavy duty trucks (EMFAC Category T7).
 (2) Construction delivery trucks are a mix of LHD1, LHD2, T6, and T7 based on data provided by Chevron. See Transmittals #20 and #36O.
3. Offsite worker vehicles are a mix of LDA (50%), LDT1 (25%), and LDT2 (25%). The split is based on CalEEMod™ default assumptions.
4. Since emission factors derived from EMFAC2011 vary by construction year, due to fleet renovation, year of construction will have an impact on the onroad vehicle emissions. Therefore total number of trips per construction year are presented in this table.
5. ENVIRON assumes that a 10-minute idling happens for a one-way trip, at each potential idling point.

		LDT2	Diesel	0.05%	25%	g
		LDT2	Gasoline	99.95%		g

Notes:
a. Onsite buses were mapped to EMFAC category "All Other Buses" and assumed 100% diesel vehicles to be conservative for the health risk analysis.
b. Information on onsite cars and pickups were provided separately. Onsite cars were assigned to EMFAC category "LDA" and assumed 100% gasoline vehicles. As EMFAC2011 indicates that less than 0.5% of the total vehicle miles travelled (VMT) is made by diesel LDA for the Contra Costa county, assuming 100% gasoline LDA will have minimal impact on the estimated health risks.
c. As suggested by Chevron, it was assumed that onsite delivery trucks are a mix of T6, T7, and LHD1/LHD2. It was further assumed that all vehicles are diesel vehicles to be conservative for the health risk analysis. See Transmittals #20 and #36O.
d. Information on onsite cars and pickups were provided separately. Onsite pickups were assigned to EMFAC category "LDT1" and assumed 98.85% diesel vehicles and 0.15% gasoline vehicles. This fuel split was based on EMFAC2011 run for the Contra Costa county for the construction years. The % diesel vehicles was calculated by dividing the VMT made by diesel LDT1 by total VMT made by all LDT1. The % gasoline vehicles was calculated by subtracting the resulted % diesel vehicles from 100%.
e. As suggested by Chevron, it was assumed that onsite flatbeds are a mix of T6, T7, and LHD1/LHD2. It was further assumed that all vehicles are diesel vehicles to be conservative for the health risk analysis. See Transmittals #20 and #36O.
f. It was assumed that soil hauling trucks that travel both onsite and offsite are heavy-heavy duty trucks (EMFAC Category T7). As suggested by Chevron, it was assumed that delivery trucks that travel both onsite and offsite are a mix of T6, T7, and LHD1/LHD2. It was further assumed that all vehicles are diesel vehicles to be conservative for the health risk analysis. See Transmittals #20 and #36O.
g. It was assumed that worker commuting vehicles are a mix of LDA (50%), LDT1 (25%), and LDT2 (25%). The split is based on CalEEMod™ default assumptions. In addition, the fuel-mix percentage for these three categories were derived the same way as described in notes b and d.
h. EMFAC2011 splits the medium-heavy duty trucks (EMFAC Category T6) and the heavy-heavy duty trucks (EMFAC Category T7) to various sub-categories. However the EMFAC2011 online database has an option of generating emission factors for EMFAC2007 categories where sub-categories are grouped. The emission factors for the T6 and T7 categories used for this analysis were generated by that option.

Notes:

- a. Input include: Contra Costa County; all speed; vehicle categories; fuel type; and calendar year.
b. Emission factor for category LHD is averaged emission factors for LHD1 and LHD2.
c. EMFAC2011 splits the medium-heavy duty trucks (EMFAC Category T6) and the heavy-heavy duty trucks (EMFAC Category T7) to various sub-categories. However the EMFAC2011 online database has an option of generating emission factors for EMFAC2007 categories where sub-categories are grouped. The emission factors for the T6 and T7 categories used for this analysis were generated by that option.
d. CO₂ emission factor incorporates Pavley standards.

Abbreviations:

ARB: California Air Resources Board
EMFAC: Emission Factor Model
CO: carbon monoxide
CO₂: carbon dioxide
CH₄: methane
g: gram
N₂O: nitrous oxide
NOx: nitrogen oxides
PM₁₀: coarse particulate matter
PM_{2.5}: fine particulate matter
ROG: reactive organic gas
TOG: total organic gas

Notes:

a. Input include: Contra Costa County; all speed; vehicle categories; fuel type; and calendar year.

b. Emission factor for category LHD is averaged emission factors for LHD1 and LHD2.

c. EMFAC2011 splits the medium-heavy duty trucks (EMFAC Category T6) and the heavy-heavy duty trucks (EMFAC Category T7) to various sub-categories. However the EMFAC2011 online database has an option of generating emission factors for EMFAC2007 categories where sub-categories are grouped. The emission factors for the T6 and T7 categories used for this analysis were generated by that option.

d. CO2 emission factor incorporates Pavley standards.

Notes:

1. Emissions were estimated using the emissions factor generated with ARB EMFAC2011 and the activity data summarized in Tables 4.3-CST-7a and 4.3-CST-7b. The equations for the calculation are explained in Table 4.3-CST-3a.
2. The emissions presented here also include brakewear and tirewear.
3. Onsite emissions are emissions occurring within the Facility boundary; offsite emissions are emissions occurring outside of Facility boundary.

Abbreviations:

CO - carbon monoxide
lb - pound
CO₂ - carbon dioxide
CO₂e - carbon dioxide equivalent
CH₄ - methane
N₂O - nitrous oxide
NOx - nitrogen oxides
PM₁₀ - coarse particulate matter
PM_{2.5} - fine particulate matter

Table A4.3-CST-11
Architectural Coating Criteria Air Pollutant Emissions
Chevron Modernization Project
Richmond, California

Phase	Year ³	Activity ⁴		ROG Emissions ⁵
		Architectural Coating (Gallons of Paint)	Paving (Acres)	(lb)
Paving ¹ - H2 Plant	2014		7.5	20
Paving ¹ - #6 H2S	2014		1.4	3.7
Architectural Coating/paint ²	2014-2015	50		104

Notes:

1. CalEEMod™ default emission factor for paving is 2.62 lb/acre of ROG.
2. CalEEMod™ default emission factor for non-residential painting/coating is $EF \text{ (lb/gal)} = C_{voc} \text{ (g/L)} / 454 \text{ (g/lb)} \times 3.785 \text{ (L/Gal)}$. The default VOC content of 250 g/L is ARB's statewide limit as indicated in CalEEMod™ User's Guide.
3. The year was based on the usage date of "Tractors/Loaders/Backhoes" for Paving, and based on the usage date of "Air Compressors" for Architectural Coating/paint, provided by Chevron.
4. The number of acres to be paved and the gallons of paint to be used for architectural coating were provided by Chevron.
5. ROG was assumed to be equivalent to VOC, in this calculation.

Abbreviations:

CalEEMod™: California Emissions Estimator Model

g: gram

gal: gallon

H2: Hydrogen Gas

H2S: Hydrogen Sulfide

L: liter

lb: pound

ROG: reactive organic gases

VOC: volatile organic gases

C_{voc}: VOC content in paint

Notes:

- The emissions due to off-road, on-road and off-gassing sources are consistent with the values and methodology described in Tables 4.3-CST-6, 4.3-CST-10, 4.3-CST-11. Note BAAQMD guidelines present the Significant Threshold for PM₁₀ exhaust and PM_{2.5} exhaust only. However PM emissions shown here and compared against thresholds includes emissions from exhaust, brakewear, and tirewear.
- BAAQMD Significance Threshold obtained from their "Adopted Air Quality CEQA Thresholds of Significance" in May 2011. Emissions for the Project are averaged over the total work days in the construction period and work days for the future construction only. Note according to Chevron, completed construction started their third quarter of 2008 and was ceased on September 1st 2009. Therefore total work days were assumed to be 132 days for 2008 and 173 days for year 2009. The other three years, 2014, 2015, and 2016 were assumed to have 261 work days per year.

Abbreviations:

CAP - criteria air pollutants
CO - carbon monoxide
CO₂ - carbon dioxide
CO₂e - carbon dioxide equivalent
CH₄ - methane
N₂O - nitrous oxide
lb - pound
MT - metric tonnes
NO_x - nitrogen oxides
PM₁₀ - coarse particulate matter
PM_{2.5} - fine particulate matter
ROG - reactive organic gas

BAAQMD. 2011. Adopted Air Quality CEQA Thresholds of Significance. May

Table A4.3-CST-13a
Fugitive Dust Emissions from Grading¹
Chevron Modernization Project
Richmond, California

Construction Year ²	Construction Phase ²	Equipment ²	Quantity ²	Daily Use (hours) ²	Days of Operation ²	Acres of Grading	VMT (miles)	PM ₁₀ Emissions (lb)	PM _{2.5} Emissions (lb)
2008	Hydrogen Plant Replacement	Grader	1	4	66	16.5	11	17	2

Notes:

1. Fugitive dust emissions from grading equipment passes are estimated using the methodology described in Table 4.3-CST-3b. The emission factor of PM₁₀ is calculated by applying a scaling factor to that of PM₁₅. Similarly, the emission factor of PM_{2.5} is scaled from that of total suspended particulates (TSP). See Table below for emission factor calculation. S: mean vehicle speed in mph. AP-42 default of 7.1 mph was used in the absence of project-specific data.

F: PM scaling factor. The AP-42 default value is 0.031 for PM_{2.5} and 0.6 for PM₁₀

The grading dust emissions were then calculated by multiplying the emission factors with the total vehicle miles traveled (VMT) for the grading equipment (i.e., grader).

$$\text{VMT} = \text{As/Wb} \times 43,560 \text{ (sqft/acre)} / 5.280 \text{ (ft/mile)}$$

Where:

As: the acreage of the grading side. The acres is based on the equipment list and days in grading phase according to the anticipated maximum number of acres a given piece of equipment can pass over in an 8-hour workday. ENVIRON uses 0.5 acres/8-hr day for grader as suggested by SCAQMD.

Wb: Blade width of the grading equipment. ENVIRON uses a default blade width of 12 ft based on Caterpillar's 140 Motor Grader.

Emission Factor Type	Equation	Emission Factor (lb/VMT)
PM ₁₅	$\text{EF}_{\text{PM15}} = 0.051 * (\text{S})^{2.0}$	2.6
PM ₁₀	$\text{EF}_{\text{PM10}} = \text{EF}_{\text{PM15}} * \text{F}_{\text{PM10}}$	1.5
TSP	$\text{EF}_{\text{TSP}} = 0.04 * (\text{S})^{2.5}$	5.4
PM _{2.5}	$\text{EF}_{\text{PM2.5}} = \text{EF}_{\text{TSP}} * \text{F}_{\text{PM2.5}}$	0.2

2. Activity data was from Chevron Transmittals #20 and #360. Consistent with CalEEMod™, activity associated with graders, crawler tractors, rubber tired dozers, and scrapers were searched.

Abbreviations:

EF: Emission Factor

PM: Particulate Matter

TSP: Total Suspended Particulates

VMT: vehicle miles traveled

Table A4.3-CST-13b
Fugitive Dust Emissions from Truck Loading¹
Chevron Modernization Project
Richmond, California

	Amount of Soil Loaded/Unloaded (tons)	PM ₁₀ Emissions (lb)	PM _{2.5} Emissions (lb)
Completed Construction	307453.35	35791	5420
Future Construction	1000	116	18

Notes:

1. Fugitive dust emissions from trucking loading are estimated using the methodology described in Table 4.3-CST-3b. See Tale below for emission factor calculation.

EF: emission factor (lb/ton)

TP: throughput of load and unload material. From Transmittal #32.

k: particle size multiplier. The AP-42 default value for PM₁₀ is 0.35 and that for PM_{2.5} is 0.053.

U: mean wind speed. Project specific mean wind speed of 8.6 mph was used.

M: material moisture content (%). The moisture content of cover (12%) was used in this calculation.

Emission Factor Type	Equation	Emission Factor (lb/ton)
PM ₁₀	$EF = k_{PM10} * 0.0032 * (U/5)^{1.3} * [1/((M/2)^{1.4})]$	0.12
PM _{2.5}	$EF = k_{PM2.5} * 0.0032 * (U/5)^{1.3} * [1/((M/2)^{1.4})]$	0.02

Abbreviations:

EF: Emission Factor

PM: Particulate Matter

USEPA: United States Environmental Protection Agency

Table A4.3-CST-13c
Fugitive Dust Emissions from On-Road Vehicle Movement¹
Chevron Modernization Project
Richmond, California

	PM ₁₀ Emissions (lb)	PM _{2.5} Emissions (lb)
Completed Construction	42	10
Future Construction	43	10

Notes:

1. Fugitive dust emissions from on-road vehicle movement on paved roads are estimated using the methodology described in Table AQ-CST-1b. See Tale below for emission factor calculation.

EF: emission factor

k: particle size multiplier (lb/VMT). ENVIRON used the PM₁₀ and PM_{2.5} particle size multiplier from Section 13.2.1-1 of USEPA AP-42.

sL: road surface silt loading (g/m²). ENVIRON used 0.2 g/m² (Ubiquitous Baseline) from AP-42.

W: average weight (tons) of the vehicles traveling the road. Based on ARB's EMFAC model.

P: number of "wet" days with at least 0.01 in of precipitation during the averaging period, ENVIRON used 60 days based on climate data from (<http://www.wrcc.dri.edu/>) for Richmond station (047414)

N: number of days in the averaging period. (365 days)

Activity data used for this calculation is presented in Tables AQ-CST-5a and b.

Chevron Modernization Project
Richmond, California

# of Tan Domes	CAP Emissions (lbs) ¹					GHG Emissions (lbs) ¹			
	ROG	NOx	CO	PM ₁₀	PM _{2.5} ²	CH ₄	N ₂ O	CO ₂	CO ₂ e
1	191	1,345	717	57	54	11	9	191,706	194,776
14	2,673	18,829	10,033	804	751	150	129	2,683,878	2,726,870

Notes:

1. The emissions due to off-road, and on-road sources are consistent with the methodology described in Tables 4.3-CST-3a. Note BAAQMD guidelines present the Significant Threshold for PM₁₀ exhaust and PM_{2.5} exhaust only. However PM emissions shown here and compared against thresholds includes emissions from exhaust, brakewear, and tirewear.
2. PM₁₀ emission factor was conservatively used as a surrogate for PM_{2.5} emission factor.

Abbreviations:

CAP - criteria air pollutants
CO - carbon monoxide
CO₂ - carbon dioxide
CH₄- methane
g - gram
GHG - greenhouse gas
lb - pound
N₂O - nitrous oxide
NOx - nitrogen oxides
PM₁₀ - coarse particulate matter
PM_{2.5} - fine particulate matter
ROG - reactive organic gas

BACKGROUND

Chevron Products Co. (Chevron or applicant) has submitted to the Bay Area Air Quality Management District (District or BAAQMD) a permit application for an Authority to Construct/Permit to Operate for the Energy & Hydrogen Renewal Project (Renewal Project or Project) at its Richmond Refinery (Refinery or facility). The Renewal Project is intended to improve the reliability, flexibility, and energy efficiency of the Refinery. The Project does not include an increase in the permitted throughput of crude oil at the Refinery. The Project is comprised of four main components:

- Hydrogen Plant Replacement
- Reformer Replacement
- Power Plant Replacement
- Hydrogen Purity Improvements

HYDROGEN PLANT REPLACEMENT

The existing 40+ year-old two-train Hydrogen Plant (180 million standard cubic feet per day (MMSCFD) total capacity) at the Refinery would be replaced with a new two-train Hydrogen Plant (280 MMSCFD total capacity). As part of the replacement of the Hydrogen Plant, the existing Hydrogen Recovery Unit (50 MMSCFD) would be replaced with a new Hydrogen Recovery Unit (50 MMSCFD). A new Cooling Tower and Flare would also be constructed as part of the Hydrogen Plant replacement.

Hydrogen is essential to produce current cleaner transportation fuels such as California gasoline. For instance, hydrogen is used by refineries for cracking and to remove impurities such as sulfur, which is required by California fuel standards. The existing Hydrogen Plant is energy inefficient, and produces relatively impure hydrogen (95% purity).

The new Hydrogen Plant would be capable of handling several different feeds including refinery process gas (RPG), refinery fuel gas (RFG), natural gas, liquefied petroleum gas (LPG, including propane), and ammonia (NH₃). RPG is gas produced by the refinery at its process units prior to going to the RFG drums where it is mixed/blended and leaves as RFG. Each train would include back-end pressure swing adsorption (PSA) units for hydrogen purification. The tail gas from the PSA units would be used to fuel the Hydrogen Plant Reformer Furnaces. The Hydrogen Plant Reformer Furnaces would normally be fired on a combination of natural gas and PSA tail gas.

During normal operation, Chevron's new Hydrogen Plant would have the capability to use RPG, natural gas, or a combination of the two, as a feedstock to the Hydrogen Plant. Chevron would prefer to start up in most instances using as much RPG as possible as a feedstock from the beginning, but that cannot be confirmed until Chevron has operating experience with the RPG portion. Chevron may instead have to use only natural gas feedstock for startup until satisfactory hydrogen product purity is achieved, and then introduce the RPG. The duration of startup should not be significantly impacted by the feedstock combination.

The feedstock composition would be that of pipeline quality natural gas whenever 100 percent natural gas feedstock is used, and a natural gas and RPG mixture during normal operation, except that the sulfur in both feedstock streams would be removed to less than 100 parts per billion (ppb). The actual use of RPG as part of the feedstock would be contingent upon stable and safe operation of the Reformers. During turndown, the natural gas flow is decreased but the RPG flow usually is not, so the RPG provides a higher percentage of the feedstock flow for that case as compared to normal operation.

Each Hydrogen Plant Reformer Furnace would be abated by Selective Catalytic Reduction (SCR). Each furnace would have a separate SCR unit and defined exhaust point. The two trains of the Hydrogen Plant would share a Cooling Tower and a Flare.

The normal operating temperature of the Hydrogen Plant Reformer Furnace will be in excess of 1,900 degrees Fahrenheit (F). The Hydrogen Plant Reformer Furnace supplier has recommended a target warm-up rate of 90 F/hour. At this rate, it would take slightly more than 20 hours of heating to reach 1,900 F. An additional four hours would be necessary to purge the nitrogen out of the PSA unit, achieve hydrogen purity (@ 99% purity), and fully route the tail gas to the furnace. As a result, a period of 24 continuous hours would be required for startup of the Hydrogen Plant.

The dryout/warmup is a series of steps that gently removes the excess moisture present in castable monolithic refractory linings. This is accomplished by heating the Hydrogen Plant Reformer Furnace at a rate no greater than 35 F/hour. In addition, several temperature hold steps are required. When the furnace temperature reaches one of the hold steps, it is held at that temperature by maintaining a constant firing rate. The hold steps occur at approximately 200 F, 400 F, 750 F, and 1,000 F. The duration of the hold steps can be as long as 24 hours each. The length of the hold step is dependent on the thickness of the castable monolithic refractory linings. After the 1,000 F hold step, the furnace is cooled at a rate of 90 F/hour until it is brought back to ambient temperature. In total, this process can take upwards of 120 hours to ensure the proper dryout of the castable monolithic refractory linings.

The SCR units are not operated during the dryout/warmup period. Dryout/warmup periods are necessary when there are significant refractory changes or refractory replacement. There are two reasons for SCR not being used during dryout/warmup. First, during this period the temperature at the SCR does not reach the minimum required temperature of 500 F in order to inject ammonia for oxides of nitrogen (NO_x) reduction. Second, should there be any dust remaining on the castable monolithic refractory linings from construction, or generated during the dryout/warmup process, it would get trapped in, and blind (or mask), the SCR.

The new Hydrogen Plant will be owned and operated by Praxair, Inc.. However, the Hydrogen Plant will be considered to be part of the Refinery for regulatory purposes including, but not limited to, the flare monitoring and control rule requirements of District Regulations 12-11 and 12-12, and the Major Facility Review requirements of Title V.

New Equipment

The proposed new equipment (i.e., sources) for the Hydrogen Plant Replacement is as follows:

S-4449 Hydrogen Plant Train #1, 140 MMSCFD Hydrogen Produced maximum capacity

S-4450 Hydrogen Plant Train #2, 140 MMSCFD Hydrogen Produced maximum capacity

S-4451 Hydrogen Recovery Unit, 50 MMSCFD Hydrogen Recovered maximum capacity

S-4471 Hydrogen Plant Train #1 Reformer Furnace, 950 million British Thermal Units per hour (MMBtu/hr) maximum firing rate higher heating value (HHV), equipped with Low-NO_x Burners abated by **A-0302** Hydrogen Plant Train #1 SCR [Vented to **P-0302** Hydrogen Plant Train #1 Furnace Exhaust]

S-4472 Hydrogen Plant Train #2 Reformer Furnace, 950 MMBtu/hr maximum firing rate HHV, equipped with Low-NO_x Burners abated by **A-0303** Hydrogen Plant Train #2 SCR [Vented to **P-0303** Hydrogen Plant Train #2 Furnace Exhaust]

S-4465 Hydrogen Plant Cooling Tower, 36,000 gallons/minute maximum capacity [Vented to **P-0304** Hydrogen Plant Cooling Tower Exhaust]

S-6021/A-6021 Hydrogen Plant Flare, 1.6 MMBtu/hr Pilot maximum capacity HHV, [Vented to **P-0305** Hydrogen Plant Flare Exhaust]

Shutdown of Existing Equipment

The following existing equipment would be shutdown as a result of the proposed Hydrogen Plant Replacement:

S-4250 Hydrogen Plant, Trains A and B, (Total Combined Capacity 150 MMSCFD) Train A abated by **A-261** Packed Bed Scrubber De-aerator Vent (Methanol), Exhaust to P-261 and Train B abated by **A-262** Packed Bed Scrubber De-aerator Vent (Methanol), Exhaust to P-262

S-4170 Hydrogen Plant Train A Reformer Furnace F-305 (820 MMBtu/hr), Exhaust to P-126 abated by **A-260** Hydrogen Plant Train A SCR System

S-4171 Hydrogen Plant Train B Reformer Furnace F-355 (820 MMBtu/hr), Exhaust to P-127, P-128, P-129, P-130

S-4348 Hydrogen Recovery Unit (1.1 ton/hour max), Exhaust to S-6039

S-4156 Feed Furnace F-320 (41 MMBtu/hr), Exhaust to P-114

S-4157 Feed Furnace F-330 (41 MMBtu/hr, Multi-fuel), Exhaust to P-115

S-4158 Feed Furnace F-340 (48 MMBtu/hr), Exhaust to P-116

REFORMER REPLACEMENT

Reforming is a refining process that increases the octane of gasoline components. Chevron's two existing naphtha octane Reformers that were originally constructed in the 1960s and 1970s would be replaced with new equipment. The existing units utilize semi-regenerative technology that requires the Reformers to shutdown twice a year to regenerate the catalyst. The existing Reformers have a combined capacity of 71,300 barrels per day (BPD) as listed on the current Refinery Title V permit. A single Reformer would replace the two existing units. The new Reformer would utilize a Continuous Catalyst Regeneration technology that would reduce shutdowns and would operate on a three to five year turnaround cycle. The new Continuous Catalyst Regeneration Reformer (CCRR) would have a capacity of 71,300 BPD. Replacing the two existing Reformers with a single unit would reduce the number of Reformer Furnaces from eight to four. The improved operation of the new CCRR, and improved hydrogen purity, would enable the Refinery to produce more California gasoline.

New Equipment

The proposed Reformer Replacement includes the following new sources and abatement devices:

S-4452 Continuous Catalyst Regeneration Reformer, 71,300 BPD maximum capacity [Vented to **P-0308** CCRR Regeneration Vent]

S-4477 Reformer Furnace #1, 201 MMBtu/hr maximum firing rate HHV, equipped with Low-NO_x Burners abated by **A-0309** SCR

S-4478 Reformer Furnace #2, 402 MMBtu/hr maximum firing rate HHV equipped with Low-NO_x Burners abated by **A-0309** SCR

S-4479 Reformer Furnace #3, 201 MMBtu/hr maximum firing rate HHV equipped with Low-NO_x Burners abated by **A-0309** SCR

S-4480 Reformer Furnace #4, 201 MMBtu/hr maximum firing rate HHV equipped with Low-NO_x Burners abated by **A-0309** SCR

A-0309 SCR for CCRR Furnaces #1 - #4 (S-4477, S-4478, S-4479, S-4480) [Vented to **P-0309** Reformer Furnaces #1 - #4 (S-4477, S-4478, S-4479, S-4480)]

Shutdown of Existing Equipment

The following existing equipment would be shutdown as a result of the proposed Reformer Replacement:

S-4283 No. 4 Catalytic Reformer (40.3 MBPD)

S-4038 No. 4 Rheniformer Furnace, F-3550 (187 MMBtu/hr), Exhaust P-40, P-41

S-4039 No. 4 Rheniformer Furnace, F-3560 (170 MMBtu/hr), Exhaust P-40, P-41

S-4040 No. 4 Rheniformer Furnace, F-3570 (152 MMBtu/hr), Exhaust P-40, P-41

S-4041 No. 4 Rheniformer Furnace, F-3580 (77 MMBtu/hr), Exhaust P-40, P-41

S-4237 No. 5 Catalytic Reformer (31 MBPD)

S-4042 No. 5 Rheniformer Furnace, F550 (198 MMBtu/hr), Exhaust P-42, P-43
Unit Equipped with 36-Ultra Low NO_x Burners

S-4043 No. 5 Rheniformer Furnace, F-560 (133 MMBtu/hr), Exhaust P-42, P-43

S-4044 No. 5 Rheniformer Furnace, F-570 (78 MMBtu/hr), Exhaust P-42, P-43

S-4045 No. 5 Rheniformer Furnace, F-580 (51 MMBtu/hr), Exhaust P-42, P-43

POWER PLANT REPLACEMENT

The Renewal Project includes the shutdown of the five existing Boilers of Power Plant No. 1 that were constructed in the 1930s and 1940s. Each of these Boilers has a maximum firing rate ranging from 233 to 272 MMBtu/hr. These Boilers would be replaced with a new Gas Turbine utilizing Heat Recovery Steam Generation Units with Duct Burners and abated by SCR and Oxidation Catalyst. The Gas Turbine would be fired on either natural gas, or a combination of natural gas and LPG. Aqueous or anhydrous ammonia is injected into the SCR catalyst to control NO_x emissions. The Duct Burners would be fired on RFG or a combination of natural gas and RFG. Chevron currently operates two other Cogeneration Units (S-4350 through S-4353).

New Equipment

The proposed Power Plant Replacement includes the following new sources and abatement devices:

S-4473 3rd Cogeneration Gas Turbine, 550 MMBtu/hr maximum firing rate HHV. Combined Gas Turbine and HRSG equipped with Duct Burners 860 MMBtu/hr firing rate (calendar day). Combined Gas Turbine and HRSG equipped with Duct Burners 840 MMBtu/hr maximum firing rate (annual average)

S-4474 3rd Cogeneration Heat Recovery Steam Generator (HRSG) equipped with Duct Burners, equipped with Low-NO_x Burners, 350 MMBtu/hr Duct Burner maximum firing rate HHV. Combined Gas Turbine and HRSG equipped with Duct Burners 860 MMBtu/hr firing rate (calendar day). Combined Gas Turbine and HRSG with Duct Burners 840 MMBtu/hr maximum firing rate (annual average)

A-74 SCR abating both 3rd Cogeneration Gas Turbine and Heat Recovery Steam Generator

A-75 Oxidation Catalyst abating both 3rd Cogeneration Gas Turbine and Heat Recovery Steam Generator [Vented to **P-0306** 3rd Cogeneration Gas Turbine/Heat Recovery Steam Generator]

Shutdown of Existing Equipment

The following existing equipment would be shutdown as a result of the proposed Power Plant Replacement:

S-4129 Boiler No. 1 (233 MMBtu/hr)

S-4131 Boiler No. 3 (236 MMBtu/hr)

S-4132 Boiler No. 4 (235 MMBtu/hr)

S-4133 Boiler No. 5 (237 MMBtu/hr)

S-4135 Boiler No. 7 (272 MMBtu/hr)

HYDROGEN PURITY IMPROVEMENTS

The Renewal Project includes the modification of existing equipment, and the installation of new process equipment, for improving hydrogen purity. The Hydrogen Purity Improvements would include the installation of new or modified equipment at the Fluidized Catalytic Cracking (FCC) Feed Hydrotreater, Sulfur Recovery Units (SRUs), and the No. 5 H₂S Unit.

New equipment to remove hydrogen sulfide (H₂S) from the FCC Feed Hydrotreater recycle hydrogen stream includes an Amine Contactor, Amine Regenerator, and Amine Storage Tanks. Alterations of the FCC Feed Hydrotreater furnaces and modifications of the FCC Feed Hydrotreater process equipment would also be part of the Hydrogen Purity Improvements. Alterations of the TKN and Poly plant furnaces are being made in order to comply with District Regulation 9, Rule 10. The current capacity of the FCC Feed Hydrotreater (S-4253 TKC Unit) is 65,000 BPD. The proposed modifications to the FCC Feed Hydrotreater would increase the capacity to 96,000 BPD.

Nine hydrogen compressors located throughout the Refinery would be modified as part of the Hydrogen Purity Improvements to preserve the present capacity with purer hydrogen streams.

The SRU modifications include a capacity increase, new process equipment, oxygen storage capability, new Sulfur Degassing Vessel, new Sulfur Loading Rack, and the installation of an additional Acid Gas Scrubber.

Hydrogen is used in several refining processes that remove impurities that naturally occur in crude oil, and in processes that convert oil to blending stocks for transportation fuels. The purity of hydrogen affects the performance of these refinery processes. The replacement of the Hydrogen Plant and Catalytic Reformer would also significantly improve the purity of hydrogen supplied to other processing units. Within these process units, hydrogen is circulated and it removes contaminants, such as nitrogen and sulfur, from the various process streams. These improvements would enhance the Refinery's ability to refine crude oil and other refinery feedstocks, or intermediates, from around the world.

The Hydrogen Purity Improvements consist of installing equipment needed to remove H₂S from the recycle hydrogen stream in the FCC Feed Hydrotreater (S-4253 TKC Unit). The following equipment would be used for this purpose: S-4454 No. 6 H₂S Plant, Recycle Amine Regenerator, and S-4456 Fresh Amine Storage Tank.

The capacity of three existing SRUs, S-4227 through S-4229, would be increased as part of this project. The modifications to the SRUs include adding process equipment and oxygen storage capability to allow oxygen enrichment into the Reaction Furnace.

Chevron would install an Acid Gas Scrubber A-4450 as part of the Hydrogen Purity Improvements. This additional acid gas scrubbing capacity, with existing A-4451, C-840 Emergency Scrubber, along with load shedding of the acid gas, would provide up to 3 hours of emergency scrubbing capacity or result in acid gas generating sources to be shutdown. Chevron would be given a permit condition limiting the acid gas feed to the three SRUs to that of the emergency scrubbing capacity. A-4450 Acid Gas Scrubber would abate #3 H₂S Plant (S-4433), #4 H₂S Plant (S-4434), #5 H₂S Plant (S-4435), Recycle Amine Regenerator (S-4454), and the #8 NH₃-H₂S Plant (S-4429) and #18 NH₃-H₂S Plant (S-4345). The Acid Gas Scrubber (A-4450) would also be used to prevent the release of acid gas during an unscheduled loss of SRU capacity.

Each SRU would be abated by a new dedicated Wet Electrostatic Precipitator (Wet ESP), which would be installed to abate sulfuric acid (H₂SO₄) mist emissions from the SRUs. The installation of the Wet ESPs will keep the H₂SO₄ emissions from the Project from exceeding the Prevention of Significant Deterioration (PSD) trigger level. The Wet ESPs would also ensure that particulate matter (PM₁₀) emissions do not increase above the baseline emissions since the Wet ESPs would reduce the PM₁₀ emissions by 90% or greater by weight. District PM₁₀ Best Available Control Technology (BACT) requirements would be satisfied through the use of the Wet ESPs.

Some other changes proposed by Chevron to improve the performance of the SRUs and to comply with both sulfur dioxide (SO₂) and carbon monoxide (CO) BACT requirements include the following:

- Reduce H₂S bypassing at the thermal oxidizer, which contributes to both SO₂ formed in the stack heater and the CO destruction efficiency;
- Improve scrubbing of SO₂, which should result in more stable operation at the higher sulfur loading; and
- Reduce the number and size of upsets caused by hydrocarbon in the acid gas feed to the

SRUs, which impacts both SO₂ and CO emissions.

New Equipment

The proposed Hydrogen Purity Improvements includes the following new sources and abatement devices:

S-4436 F-2170 Stack Gas Heater No. 1 SRU, 31.9 MMBtu/hr maximum firing rate HHV [vented to **P-0151** SRU Train #1 Exhaust]

S-4437 F-2270 Stack Gas Heater No. 2 SRU, 31.9 MMBtu/hr maximum firing rate HHV [Vented to **P-0152** SRU Train #2 Exhaust]

S-4438 F-2370 Stack Gas Heater No. 3 SRU, 56.1 MMBtu/hr maximum firing rate HHV [Vented to **P-0153** SRU Train #3 Exhaust]

S-4454 #6 H₂S Plant, Recycle Amine Regenerator, 11 MMSCFD maximum capacity

S-4490 Sulfur Loading Rack, 157 LT/hour maximum capacity abated by **A-0310** Sulfur Loading Rack Caustic Scrubber [Vented to **P-0310** Sulfur Loading Rack Caustic Scrubber Exhaust]

A-4450 Acid Gas Scrubber (C-2440), 11 MMSCFD Acid Gas for abatement of: #3 H₂S Plant

(S-4433), #4 H₂S Plant (S-4434), #5 H₂S Plant (S-4435), Recycle Amine Regenerator (S-4454), #8 NH₃-H₂S Plant (S-4429), and #18 NH₃-H₂S Plant (S-4345)

A-4451 Acid Gas Scrubber (C-840), 12.5 MMSCFD Acid Gas for abatement of: #3 H₂S Plant (S-4433), #4 H₂S Plant (S-4434), #5 H₂S Plant (S-4435), Recycle Amine Regenerator (S-4454), the #8 NH₃-H₂S Plant (S-4429), and #18 NH₃-H₂S Plant (S-4345)

S-4456 Fresh Amine Storage Tank, 70,000 gallon maximum capacity

S-3227 Lean Amine Storage Tank, 130,000 gallon maximum capacity

S-3228 Caustic Storage Tank, 200,000 gallon maximum capacity

S-3229 Spent Caustic Storage Tank, 400,000 gallon maximum capacity

Modification of Existing Equipment

The following existing equipment (i.e., sources) would be modified as a result of the proposed Hydrogen Purity Improvements:

S-4253 TKC/FCC Feed Hydrotreater, 96,000 BPD maximum capacity

S-4435 No. 5 H₂S Plant, 9.6 MMSCFD maximum capacity

S-4227 Sulfur Recovery Unit Train #1, 345 LTD maximum capacity, abated by both **A-0020** SRU#1 Tail Gas Unit Thermal Oxidizer, 30.8 MMBtu/hr HHV maximum firing rate and **A-120** Wet Electrostatic Precipitator (ESP)

S-4228 Sulfur Recovery Unit Train #2, 345 LTD maximum capacity, abated by **A-0021** SRU#2 Tail Gas Unit Thermal Oxidizer, 30.8 MMBtu/hr HHV maximum firing rate and **A-121** Wet Electrostatic Precipitator (ESP)

S-4229 Sulfur Recovery Unit Train #3, 570 LTD maximum capacity, abated by **A-0022** SRU#3 Tail Gas Unit Thermal Oxidizer, 45.0 MMBtu/hr HHV maximum firing rate and **A-122** Wet Electrostatic Precipitator (ESP)

Other Altered Equipment

Retrofitting of Existing Furnaces with Low NO_x Burners (Reg. 9-10 Compliance)

S-4161 F-510 TKN Furnace, 61 MMBtu/hr maximum firing rate HHV, equipped with Low-NO_x Burners [Vented to **P-0311** TKN Furnace Exhaust]

S-4162 F-520 TKN Furnace, 61 MMBtu/hr maximum firing rate HHV, equipped with Low-NO_x Burners [Vented to **P-0311** TKN Furnace Exhaust]

S-4163 F-530 TKN Furnace, 61 MMBtu/hr maximum firing rate HHV, equipped with Low-NO_x Burners [Vented to **P-0311** TKN Furnace Exhaust]

S-4188 F-651 Polymer Furnace, 27 MMBtu/hr maximum firing rate HHV, equipped with Low-NO_x Burners [Vented to **P-0312** Polymer Furnace Exhaust]

S-4189 F-661 Polymer Furnace, 15 MMBtu/hr maximum firing rate HHV, equipped with Low-NO_x Burners [Vented to **P-0313** Polymer Furnace Exhaust]

PROJECT EMISSIONS

PLANT CUMULATIVE INCREASE

In general, estimates of criteria pollutant emissions (precursor organic compounds (POC), nitrogen oxides (NO_x), particulate matter (PM₁₀), sulfur dioxide (SO₂), and carbon monoxide (CO)) from the Renewal Project fall into the following categories: Combustion, fugitive components, cooling tower, and process units/miscellaneous.

Project combustion sources, including Furnaces, Cogeneration Units (Gas Turbine/Duct Burner), and Flare

The District uses a number of methodologies to estimate emissions. For combustion sources subject to the District BACT requirements, where NO_x and CO concentrations are limited, emissions are estimated using the permit condition concentration limits and either the maximum, or permitted maximum, exhaust flow rate. For SO_2 emission estimates, the total sulfur concentration contained in the fuel combusted is assumed to convert 100 percent to SO_2 emissions. For the other criteria pollutants (PM_{10} and POC), and sources which are not limited by concentration, emission factors are used to estimate the emissions. These emission factors may be available from either a vendor/manufacturer guarantee or a suitable United States Environmental Protection Agency (EPA) AP-42 emission factor.

Combustion sources in the Renewal Project, with the exception of the flare, would be equipped with continuous emission monitors for both NO_x and CO emissions. For SO_2 emissions, both the total sulfur concentrations contained in the fuel and the fuel flow would be continuously monitored. Periodic source testing will be required for the other criteria pollutants.

Project Fugitive Components

The District performed fugitive emission estimates for this project using the Correlation Equation Method in the “California Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities (February 1999).” The District verified that Chevron’s leak detection and repair program (LDAR) would be using the approved 10,000 parts per million (ppm) pegged leaker emission factor as opposed to the 100,000 ppm emission factor, since the latter was developed using very few data points. The District also reserves the right, in the permit conditions, to approve the calculation methodology to be used in order to demonstrate compliance with emission estimates, offsets, etc. on an ongoing basis. The emission factors used in the emissions estimate are based on Chevron’s LDAR for similar source categories within the Refinery. The emission factors used correspond to an average leak rate much less than the 100 ppm limit in District Regulation 8-18, or current District BACT guidelines. The LDAR program will be used to demonstrate compliance with the emission limits specified in the permit conditions that also correspond to the specific number of components associated with this project. A more detailed description of the fugitive emissions estimate is contained in the BACT section of this document.

Project Cooling Tower

The Hydrogen Plant Cooling Tower PM_{10} emissions calculation is based on a maximum drift rate (as percent of circulation) of 0.0005%. The derivation of the emission factor (0.208 pounds of PM_{10} per million gallons of water circulation rate (lb PM_{10} /MMgal)) used in the Emissions Worksheet is presented in Table 1.

Table 1 – Hydrogen Plant Cooling Tower Emissions Worksheet	
Parameter	Value

Table 1 – Hydrogen Plant Cooling Tower Emissions Worksheet	
Maximum total dissolved solids (TDS) content of circulating water, mg/L or parts per million by weight (ppmw)	5,000
Maximum drift rate, % of circulation rate	0.0005%
Emission factor, lb PM ₁₀ /MMgal circulation rate (0.0005% * 8.33 lb/gal * 5,000 ppmw)	0.208

When this emission factor is used in the Emissions Worksheet with a maximum circulation rate of 36,000 gallons per minute (gpm), the resulting emission rate is:

$$(36,000 \text{ gpm}) * 60 * 24 * 365 / 1,000,000 = 18,922 \text{ MMgal/year}$$

$$18,922 \text{ MMgal/year} * 0.208 \text{ pound (lb) PM}_{10}\text{/MMgal} / 2000 = 1.97 \text{ tons/year PM}_{10}$$

The POC emissions from the Hydrogen Plant Cooling Tower were estimated using an emission factor from EPA AP-42.

Project Process Units/Miscellaneous Units including: Sulfur Recovery Units, CCRR Vent, and Sulfur Loading Rack

Whenever available, the District uses maximum, or permitted maximum, concentrations with maximum, or permitted maximum, exhaust flow rates to determine the respective emissions. In other cases, the District uses either vendor or manufacturer's guarantees, EPA AP-42 emission factors, or other appropriate emission factors or studies. Verification of emissions is to be done either through continuous emission monitors or source testing.

Detailed Emissions Estimates contained in Appendix A

The detailed methodology used to determine the Plant Cumulative Increase/Criteria Pollutant Emissions Estimates is provided in Appendix A. Appendix A contains calculation spreadsheets (or tables) that are organized by criteria pollutant, followed by an explanation of the calculation method for each pollutant, organized by source. Each spreadsheet in Appendix A also includes the basis for the criteria pollutant emission estimates, by source.

Any reductions in emissions presented in Appendix A represent actual emission reductions used for California Environmental Quality Act (CEQA) and Prevention of Significant Deterioration (PSD) purposes only. These reductions have not been Reasonably Available Control Technology (RACT) adjusted or otherwise reviewed for compliance with District banking or offset requirements. Table 2 provides a summary of emission offsets that are required for the Renewal Project.

Table 2 – Plant Cumulative (Criteria Pollutant) Emissions Increase and Offsets required for the Renewal Project				
Pollutant	Project Emission Increases (cumulative, in tons per year)	Project Emission Offsets Required (in tons per year)	Refinery Emission Reduction Credits Available (in tons per year)	Emission Reduction Credits (Banking Certificate #)
POC	69.34	79.74	236.22	TBD
NO _x	141.20	162.38	162.46	TBD
PM ₁₀	47.95	47.95	45.32	TBD
SO ₂	58.50	58.50	134.67	TBD
CO	147.03	Not applicable	Not applicable	Not applicable

Table 2 does not list the specific Emission Reduction Credits (ERCs) that would be used for the Project. Chevron has requested that the District issue the Authority to Construct using its existing banked ERCs, and review at a later date the ERCs from shutdown sources associated with the Renewal Project. Again, the emission reductions identified in Appendix A were used for CEQA and PSD purposes only. ERCs from the shutdown sources will be evaluated in another application to be submitted by Chevron.

For PM₁₀ emissions, Chevron does not have sufficient PM₁₀ ERCs in the District bank. For CEQA and PSD purposes, the Project PM₁₀ reductions are 89.15 tons per year, since the Project increase is 47.95 tons per year, this should be adequate to offset the PM₁₀ emissions increases. The banked PM₁₀ ERCs of 45.32 tons per year and the shutdown of one of the Project's large Hydrogen Plant Furnaces (S-4171) alone should adequately offset the PM₁₀ emissions increases. Additionally, other Project furnaces will be shutdown and Chevron has SO₂ ERCs in the bank that may be used to offset PM₁₀ emissions increases when adjusted by an appropriate offset ratio.

Table 3 provides a summary of PSD Emissions Increases, Contemporaneous Reductions, and Net Emissions

Table 3 – PSD Emissions Increases, Contemporaneous Reductions, and Net Emissions for the Renewal Project				
Pollutant	Project PSD Emission Increases (in tons/year or lb/day)	Contemporaneous Actual Emission Reductions for Netting (in tons/year or lb/day)	Net Emissions (in tons/year or lb/day)	PSD Trigger Levels (in tons/year or lb/day)
POC	69.87	63.09	6.78 tons/year	40 tons/year
NO _x	174.90	220.47	-45.57 tons/year	40 tons/year
PM ₁₀	66.06	89.15	-23.09 tons/year	15 tons/year
SO ₂	116.14	104.65	11.49 tons/year	40 tons/year
CO	278.75	184.39	94.36 tons/year	100 tons/year
H ₂ SO ₄	16.5	18.97	-2.47 tons/year	7 tons/year
H ₂ SO ₄	90.41 lb/day	103.94 lb/day	-13.53 lb/day	38 lb/day
H ₂ S	4.83	n/d*	< 10 tons/year	10 tons/year
H ₂ S	27.12 lb/day	n/d*	< 55 lb/day	55 lb/day

* Note: The Renewal Project H₂S emissions increases alone did not exceed the PSD trigger levels without taking into account any reductions from shutdown sources at the Refinery for netting purposes.

Shakedown Period and PSD Netting

EPA regulations and guidance indicate when to start counting emission increases from a new or replacement unit at a facility for the purpose of determining applicability of PSD requirements.

According to 40 CFR 52.21(b)(3)(viii) the definition of “net emissions increase” specifies that “an increase that results from a physical change at a source occurs when the emissions unit on which construction occurred becomes operational and begins to emit a particular pollutant. Any replacement unit that requires a shakedown becomes operational only after a reasonable shakedown period, not to exceed 180 days.”

The EPA’s October 1990 draft “NSR Manual” (at page A.38) also provides guidance on the issue:

"An increase resulting from a physical change at a source occurs when the new emissions unit becomes operational and begins to emit a pollutant. A replacement that requires a shakedown period becomes operational only after a reasonable shakedown period, not to exceed 180 days. Since the date construction actually will commence is unknown at the time the applicability determination takes place and is simply a scheduled date projected by the source, the contemporaneous period may shift if construction does not commence as scheduled. Many States have developed PSD regulations that allow different time frames for definitions of contemporaneous. Where approved by EPA, the time periods specified in these regulations govern the contemporaneous timeframe."

Similar to EPA regulations, the maximum length of the “shakedown period” allowed under District regulations is 180 days, as specified in Regulation 2-1-411 (note that the District uses the analogous term “start-up period” instead of “shakedown period”). District Regulation 2-2-

410 provides an additional requirement for replacement sources whereby the simultaneous operation of existing and new sources involved in the replacement may not exceed 90 days. Consistent with federal PSD requirements, the District will determine PSD applicability based on emissions starting at the end of the start-up period for a replacement source (subject to the additional District requirement of no more than 90 days of simultaneous operation of the existing and new sources involved in the replacement).

Baseline Period Emissions (For Sources to be Shutdown)

The baseline period for the Renewal Project was established to be the three years prior to the submittal of the District permit application. For new/modified sources, the emission calculation procedure specified in District Regulation 2-2-605 was followed. Regulation 2-2-605 requires that the baselines be RACT-adjusted. RACT is defined differently for sources that will continue to operate or that are being shutdown, as is specified in the definition given below. As was previously indicated, for PSD and CEQA purposes a RACT adjustment is not required and, therefore, was not performed.

2-2-243 Reasonably Available Control Technology (RACT): For sources which are to continue operating, RACT is the lowest emission limit that can be achieved by the specific source by the application of control technology taking into account technological feasibility and cost-effectiveness, and the specific design features or extent of necessary modifications to the source. For sources which are or will be shut-down, RACT is the lowest emission limit that can be achieved by the application of control technology to similar, but not necessarily identical categories of sources, taking into account technological feasibility and cost-effectiveness of the application of the control technology to the category of sources only and not to the shut-down source.

TOXIC AIR CONTAMINANT EMISSIONS

The District performed a Regulation 2, Rule 5 Health Risk Screening Analysis (HRSA) as part of the evaluation of the Renewal Project permit application. The toxic air contaminant emissions calculations are shown in Appendix B. The HRSA considers the emissions from new and modified sources, and does not consider reductions in emissions that will result from the shutdown of existing sources. Table 4 includes a summary of the toxic air contaminant emission rates, in both pounds per hour and pounds per year, and the acute and chronic risk screening trigger levels specified in Regulation 2, Rule 5.

Table 4 – Renewal Project Toxic Air Contaminant Summary Table				
Toxic Air Contaminant	Project Wide lb/year	Project Wide lb/hour	Acute Risk Screening Trigger Level (lb/hour)	Chronic Risk Screening Trigger Level (lb/year)

STATEMENT OF COMPLIANCE

This section summarizes the applicable District Rules and Regulations, and describes how the proposed Renewal Project will comply with them.

District Regulation 2, Rule 2: New Source Review

The primary requirements of the District's New Source Review (NSR) rule that apply to the Renewal Project are Regulation 2-2-301: "Best Available Control Technology Requirement," Section 2-2-302: "Offset Requirements, Precursor Organic Compounds and Nitrogen Oxides, NSR," and Section 2-2-303: "Offset Requirements, PM₁₀ and Sulfur Dioxide, NSR." Section 2-2-304: "PSD Air Quality Analysis" is not triggered due to the netting of emissions created by the emission reductions from shutdown sources occurring at the Refinery as a result of the Renewal Project.

Best Available Control Technology Determinations

Pursuant to District Regulation 2-2-206, BACT is defined as the more stringent of:

- (a) "The most effective control device or technique which has been successfully utilized for the type of equipment comprising such a source; or
- (b) The most stringent emission limitation achieved by an emission control device or technique for the type of equipment comprising such a source; or
- (c) Any emission control device or technique determined to be technologically feasible and cost-effective by the APCO; or
- (d) The most effective emission control limitation for the type of equipment comprising such a source which the EPA states, prior to or during the public comment period, is contained in an approved implementation plan of any state, unless the applicant demonstrates to the satisfaction of the APCO that such limitations are not achievable. Under no circumstances shall the emission control required be less stringent than the emission control required by any applicable provision of federal, state or District laws, rules or regulations."

The type of BACT described in definitions (a) and (b) above must have been demonstrated in practice and approved by a local Air Pollution Control District, California Air Resources Board

(CARB), or the EPA, and is referred to as “BACT 2.” This type of BACT is also referred to as "achieved in practice." The BACT category described in definition (c) is referred to as "technologically feasible/cost-effective" and it must be commercially available, demonstrated to be effective and reliable on a full-scale unit, and shown to be cost-effective on the basis of dollars per ton of pollutant abated. This is referred to as “BACT 1.” BACT specifications (for both the "achieved in practice" and “technologically feasible/cost-effective" categories) for various source categories have been compiled in the District’s BACT/Toxics Best Available Control Technology (TBACT) Workbook. The BACT/TBACT Workbook is a guideline document and may not in all cases represent current BACT or the latest information available.

Table 5 indicates the sources in the Renewal Project that are required to use BACT.

Table 5 - Renewal Project Sources subject to BACT

S-4229	Sulfur Recovery Unit No. 3	Yes	No	No	No	Yes	No
S-4438	Stack Gas Heater for SRU No. 3	Yes	No	No	No	Yes	No

Notes: SO₂ Emissions from sources burning Refinery Fuel Gas are limited by permit limits on the sulfur content of the Refinery Fuel Gas System.

CCRR Reformer Furnaces S-4477 through S-4480 share a common exhaust point.

Each SRU and corresponding Stack Gas Heater share a common exhaust point.

Sources being retrofitted with Low NO_x burners to meet District Regulation 9, Rule 10 requirements are exempt from BACT per Regulation 1-115 and are not included in this Table.

BACT for Fugitive Components

The fugitive components (i.e., valves, flanges, pumps, compressors, etc.) to be installed as part of the Renewal Project would satisfy the District BACT requirements.

BACT for petroleum refinery fugitive components per the District's BACT/TBACT Workbook is the following:

- Flanges leak level of 100 ppm as methane (BACT Level 2, Level 1 not determined (n/d)).
- Valves leak level of 100 ppm as methane (BACT Level 2, Level 1 n/d).
- Pumps leak level of 100 ppm as methane (BACT Level 2).
- Compressors leak level of 100 ppm as methane (BACT Level 2).
- Pressure Relief Valves, Emergency releases vented to fuel gas recovery system, furnace, or flare with a recovery/destruction efficiency $\geq 98\%$.

The "Typical Technologies" listed in the BACT/TBACT Workbook for each component type are indicated below:

- Flanges require: graphitic gaskets.
- Valves require: Bellows Valves, Diaphragm Valves, Quarter Turn Valves, Live Loaded Valves, or Other Low-Emission Valves (District Approved).
- Pumps require: Double Mechanical Seals with Barrier Fluid, Magnetically Coupled Pumps, Canned Pumps, Magnetic Fluid Sealing Technology, or Gas Seal System vented to District-approved control device.
- Compressors require: Double Mechanical Seals with Barrier Fluid, oil ring seals with non-VOC seal/barrier fluid, or Gas Seal System vented to District-approved control device.
- District-approved fugitive component inspection and maintenance program.

The District can approve equivalent technologies. The District also requires quarterly inspections for all component types except for flanges and connectors, which require biannual inspections.

For the Renewal Project, BACT for fugitive components in heavy liquid service is defined for materials with a flash point of less than or equal to 250 F. The District's Regulation 8-18 contains a limited exemption for monitoring of fugitive components with a boiling point greater than 302 F. For this project, the District has increased the population of components that is subject to control and monitoring beyond that of Regulation 8-18 to those components in hydrocarbon service up to, and including, a flashpoint of 250 F. This hydrocarbon service definition was based on SCAQMD requirements, and is achieved in practice in that district.

For this project, Chevron proposed using results of its current LDAR program to determine emission factors for each component type. Historically, project fugitive emission estimates have used a less refined method based on the maximum allowable emissions under District Regulation 8-18 (i.e., each component at 100 ppm plus allowable pegged leaker emissions) for the purposes of determining both cumulative increase and offsets. The new approach creates a much lower allowable emissions level for the total project fugitive emissions. Any individual component would still be subject to the 100 ppm BACT limit, but, for the purposes of cumulative increase and/or offsets, the LDAR results were used for the emissions estimate. This lower emissions estimate will be enforced through the LDAR program and a permit condition corresponding to the emissions estimate using this approach for the specified component counts. Chevron must demonstrate compliance with the permitted emissions level on an ongoing basis.

The Renewal Project fugitive components that are in hydrocarbon service with a flash point less than or equal to 250 F, will be subject to permit conditions that require all fugitive components associated with the Renewal Project to meet BACT requirements, including the use of low-emission equipment, individual concentration limits, inspection and maintenance frequencies, and quarterly mass emissions calculations demonstrating compliance with a mass emissions limit corresponding to the permitted component counts.

BACT for Refinery Process Heaters (>50 MMBtu/hr)

The following BACT guidelines were reviewed for determining BACT emission rates for the Renewal Project combustion sources with a firing rate greater than 50 MMBtu/hr: BAAQMD, SCAQMD, CARB BACT Clearinghouse, and the EPA BACT/LAER Clearinghouse. The applicable BACT guidelines, and the required BACT standards for the Renewal Project, are shown in Table 6.

The Renewal Project sources with emission increases that are subject to BACT requirements are: the Hydrogen Plant Reformer Furnaces (S-4471, S-4472) and the Continuous Catalytic Regenerative Reformer Furnaces (S-4477 through S-4480).

Hydrogen Plant Furnaces

S-4471 Hydrogen Plant Train #1 Reformer Furnace (950 MMBtu/hr)

S-4472 Hydrogen Plant Train #2 Reformer Furnace (950 MMBtu/hr)

These Hydrogen Plant Reformer Furnaces will normally be fired on a combination of natural gas and Pressure Swing Absorber tail gas. Each furnace will be abated by an SCR unit and have a separate exhaust stack. The required emission limits for NO_x and CO shown in Table 6 are more stringent than those in the current District BACT/TBACT Workbook, which is being updated as a result of this Project, and are in agreement with other recent District BACT determinations. BACT for POC and PM₁₀ emissions includes utilizing good combustion practice, and the use of natural gas or treated RFG with low sulfur content, rather than a specific numerical emission limit. BACT for SO₂ is the use of low-sulfur natural gas mixed with Pressure Swing Absorber tail gas, which is also low in sulfur. The Hydrogen Plant Furnaces (S-4471, S-4472) will satisfy the BACT requirement of District Regulation 2-2-301.

Continuous Catalytic Regenerative Reformer Furnaces

S-4477 CCRR Reformer Furnace (201 MMBtu/hr)

S-4478 CCRR Reformer Furnace (402 MMBtu/hr)

S-4479 CCRR Reformer Furnace (201 MMBtu/hr)

S-4480 CCRR Reformer Furnace (201 MMBtu/hr)

These CCRR Reformer Furnaces are normally fired on RFG, but would also have the capability to burn natural gas. All four furnaces will share a common exhaust stack and will be abated by a single SCR unit. The proposed emission limits for NO_x and CO (5 and 10 ppm, respectively) shown in Table 6 below meet the current District BACT guidelines. BACT for POC and PM₁₀ emissions includes utilizing good combustion practice, and the use of natural gas or treated RFG with low sulfur content, rather than a specific numerical emission limit. BACT for SO₂ is a refinery-wide permit limit on the sulfur content on the RFG system, including both short-term and long-term total sulfur (TS) and H₂S limits. Short-term (or daily) limits on fuel gas would be: 100 ppm TS and 50 ppm H₂S. Long-term (or annual average) limits on fuel gas would be: 30.85 ppm TS and 18.83 ppm H₂S. The long-term limits on the RFG system will be used to create SO₂ ERCs. The continuous catalyst regeneration reformer furnaces meet the BACT requirement of District Regulation 2-2-301.

BACT for Hydrogen Plant Cooling Tower

Under District NSR requirements, the Hydrogen Plant Cooling Tower S-4465 is subject to BACT for PM₁₀ since emissions of PM₁₀ from this source would be greater than 10 lb/day.

The District's BACT/TBACT Workbook does not specify BACT for PM₁₀ emissions from Wet Cooling Towers. However, the CARB BACT Clearinghouse cites a BACT specification for PM₁₀ emissions for the proposed La Paloma Power Plant Cooling Tower as the use of drift eliminators with a maximum drift rate of 0.0006%. The cooling towers for the Los Medanos Energy Center, Delta Energy Center, and Metcalf Energy Center are equipped with drift eliminators with a guaranteed drift rate of 0.0005%.

The proposed Hydrogen Plant Cooling Tower would also be equipped with drift eliminators with a drift rate of 0.0005%. The Cooling Tower drift rate is based on an equipment vendor guarantee. This technology will satisfy the BACT requirement for PM₁₀ emissions from this source.

BACT for POC from a cooling tower is a combination of monitoring and repair frequency. Praxair/Chevron will be required in the permit conditions to inspect the Cooling Tower riser chamber in the cooling water return line daily for hydrocarbon leaks. The District will not require the installation of a hydrocarbon analyzer at this time since the Hydrogen Plant Cooling Tower would be permitted to only 15 days of hydrocarbon leakage during any consecutive 12-month period. Praxair/Chevron asserts that a hydrocarbon leak is unlikely. Should a hydrocarbon leak be detected, the leak must be repaired within 15 calendar days, which is consistent with other BACT determinations. If it is determined in the future that POC emissions for the Hydrogen Plant Cooling Tower are greater than originally estimated, at either a maximum daily emission rate of 36 lb/day or a maximum annual emission rate of 0.27 ton per year (which corresponds to 15 leaking days), then Chevron must submit a permit application to the District.

BACT for Hydrogen Plant Flare

The Hydrogen Plant Flare S-6021 is subject to BACT since it would emit more than 10 pounds per highest day of NO_x, CO, SO₂, and POC. BACT is not triggered for PM₁₀.

The main purpose of the flare is to dispose of hydrogen (H₂), methane (CH₄) and CO in an emergency, for safety reasons. Hydrogen and methane are not considered pollutants. The Hydrogen Plant Flare will only be used during periods of planned startup/shutdown, and periods of flaring caused by an emergency as allowed in the District-approved Flare Minimization Plan (FMP). This is consistent with BACT2 for refinery flares, which limits the flare operation to periods of emergency plant upset or breakdown. It also requires that routine venting of process gases be routed to a fuel gas recovery system. The process stream of most concern is associated with PSA 3, which handles the RPG received from Chevron. Praxair will operate a process compressor on this stream and will use this same compressor to return RPG to Chevron during most upset conditions. However, Praxair has identified certain instances where a small amount of RPG will need to be flared. These instances will be reviewed in greater detail through the District' FMP process.

The District will be including enforceable, permit condition-like, language into the Praxair FMP that will limit the operation of the flare, since this flare has triggered NSR review.

The District's BACT/TBACT Workbook states that an enclosed ground-level flare with a control efficiency of 98.5% for POC is BACT1. BACT1 for CO is undetermined at this point. The District has determined that an enclosed ground-level flare is not cost-effective for this project. This determination was based on information submitted by Chevron regarding the cost of installing an enclosed ground-level flare.

BACT2 for POC, CO, and NO_x is an elevated flare, steam- or air-assisted, POC destruction efficiency >98% by weight; use of natural gas or LPG as pilot fuel. Praxair has agreed to use steam-assist to satisfy BACT during all flaring events. BACT for SO₂ is not determined in the BACT/TBACT Workbook. However, the flare pilot will be fired exclusively on natural gas, which will minimize SO₂ emissions.

Also, the Hydrogen Plant Flare will be subject to the District's flare monitoring and control regulations, Regulation 12, Rule 11 and 12.

The proposed Hydrogen Plant Flare is expected to achieve a BACT2 level control efficiency of 98% by weight for POC and CO. This 98% control efficiency is based on the EPA AP-42 chapter on industrial flares and a previous determination made by the District's Advisory Council. District Regulation 12-11-401.9 requires that an efficiency of 93% be used when the heating value is less than 300 Btu/scf. However, for the purposes of both the District permit conditions and permitted emission estimates, a 98% destruction efficiency by weight may be used if the owner/operator satisfies the required parameters (H₂ content, tip velocity, and lower heating value) specified in the EPA Emission Standards Division Report ("Basis and Purpose Document on Specifications for Hydrogen-Fueled Flares," dated March 1998) and adequately monitors these required parameters. If there are any problems related to the monitoring of the parameters required to meet the 98% destruction efficiency, then 93% destruction efficiency must be used for both Regulation 12-11-401.9 and the permitted emissions.

The Hydrogen Plant Flare S-6021 will satisfy BACT2 for CO, POC, NO_x, and SO₂ as required by District Regulation 2-2-301.

BACT for Continuous Catalyst Regenerative Reformer

The CCRR S-4452 is subject to BACT since it emits more than 10 pounds per highest day of CO. Chevron has adjusted the emission factors supplied by the equipment vendor due to the uncertainty of the emission values from this unit. Based on the limited emissions information available for this source category, the permitted emissions for PM₁₀, NO_x, POC and SO₂ would not exceed 10 lb/highest day based on the maximum permitted concentrations and flowrate for this source. Chevron has accepted District permit conditions to limit the criteria pollutant emissions below 10 lb/highest day for all criteria pollutants other than CO.

The following BACT guidelines were reviewed for determining BACT emission rates for the CCRR vent: BAAQMD, SCAQMD, CARB BACT Clearinghouse, and the EPA BACT Clearinghouse. No applicable BACT guidelines are available for this source category.

The CCRR CO emissions were calculated using an emission factor supplied by the equipment vendor that was adjusted by Chevron for compliance assurance to 5.48×10^{-4} lb per barrel.

As part of the process design, UOP (the equipment vendor) estimated the CCRR vent gas CO concentration to be 252 parts per million by weight (ppmw) (270 parts per million by volume (ppmv)). CCRR vent gas CO concentrations are not well documented. Further, there are metallurgical limits on the temperature at which the regenerator can be operated, and this limits the amount of CO destruction that can occur in the regenerator. As a result, UOP will not guarantee a maximum CO concentration.

To find a suitable compliance limit, Chevron and its consultants conducted an independent search of existing regulations for limits on CO emissions from catalytic reformers but were unable to find any limits directly relevant to this application. The Refinery maximum available control technology (MACT) II rule¹ however does specify a 500 ppmv (dry basis) standard for CO from Fluid Catalytic Cracking (FCC) regenerator vents.

The District was unable to locate any BACT determinations for CO emissions from a CCRR vent. The District determined that the referenced MACT II limit for FCCs represents an appropriate CO emission limit for the CCRR vent gas. Compliance with the 500 ppmv limit will be confirmed through the periodic source testing requirements specified in Permit Conditions Parts 57, 58, and 59.

Table 7 - CCR Vent CO Emissions - Adjustments from UOP Estimates to Maximums					
Pollutant	UOP Est. Concentration ppmw	UOP Estimated Emissions	Maximum Concentration ppmv	Maximum Emissions lb/yr	Maximum Emissions tons/yr
CO	252	7560 lb/yr 20.71 lb/day	500	13,993	7.0

BACT for Cogeneration Gas Turbine and Heat Recovery Steam Generator with Duct Burners

Nitrogen Oxides (NO_x)

The District BACT/TBACT Workbook specifies BACT Level 1 for NO_x for a combined-cycle Gas Turbine with a power rating ≥ 40 megawatt (MW) as a NO_x concentration not to exceed 2.0 ppmvd @ 15% O₂, averaged over one hour for natural gas firing. This emissions level has been achieved through the use of SCR with ammonia injection in conjunction with combustion modifications. BACT Level 2 is a concentration not to exceed 2.5 ppmvd @ 15% O₂ (averaged over 3 hours) when firing a combination of natural gas and RFG.

¹ 40CFR Part 63 Subpart UUU Table 8; National Emission Standards for Hazardous Air Pollutants for Petroleum Refineries: Catalytic Cracking Units, Catalytic Reforming Units, and Sulfur Recovery Units.

Since there is no published BACT determination for a Gas Turbine fired on natural gas and a combination of natural gas and liquefied petroleum gas (LPG) with HRSG Duct Burners firing RFG or a combination of RFG and natural gas, a case-by-case BACT analysis has been performed. The District has determined that BACT for NO_x for this Project is an SCR system designed to achieve 2.0 parts per million, volumetric dry (ppmvd) @ 15% O₂ (three-hour average) and 2.5 ppmvd @ 15% O₂ (one-hour average). The permit condition is written using the word “and” instead of “or” since using “and” means that both limits must be exceeded to be out of compliance. This determination is based on a review of NO_x continuous emission monitoring (CEM) data that demonstrated that these emissions levels are achieved in practice at the Valero Cogeneration project permitted in 2001 (Application No. 2488 and 2695). Similar to Valero, Chevron will be required to adjust its fuel selection in order to satisfy the NO_x BACT requirement.

Two relatively new technologies are capable, under some conditions, of controlling NO_x emissions from a gas turbine to 2 ppmvd or below. These are: SCONO_x, manufactured by Goal Line Environmental Technologies, and XONON, manufactured by Catalytica, Inc. The District has reviewed these technologies to determine if the technologies are appropriate for this application. SCONO_x is the more established of the two technologies. This system uses a potassium carbonate coated catalyst to remove both NO_x and CO, without the use of a reagent such as ammonia. There are two systems in commercial operation on a Gas Turbine of comparable size to that being used in the Renewal Project. This system has demonstrated that SCONO_x can consistently achieve NO_x levels comparable to those achieved by SCR on medium-sized (~50 MW) turbines. The District considers this technology equivalent to the use of SCR for medium-sized turbines, and would approve a project that proposed its use.

XONON, developed by Catalytica, Inc., is another promising new technology for NO_x emissions control. This technology uses a flameless catalyst located inside the combustion chamber itself, which allows for the combustion reaction to proceed at a lower temperature than in conventional turbines, thus minimizing the formation of NO_x.

At the present time, the commercial availability of XONON technology is extremely limited. To date, District staff is aware of only one application, a 1.5 MW turbine in Santa Clara, California. There is no information available regarding the operation of such a system on a turbine the size of the one to be installed for the Renewal Project, which is over 25 times larger. Based on this information, XONON does not represent a technologically feasible control option for the Renewal Project.

In summary, XONON is not technologically feasible for this project. SCR and SCONO_x are both feasible, and achieve equivalent NO_x reductions. Chevron’s choice of SCR to achieve the NO_x BACT control levels described above are therefore acceptable.

The SCR unit will inject aqueous or anhydrous ammonia into the SCR catalyst to control NO_x emissions. The ammonia slip will be limited by permit condition to 10.0 ppmvd. While some recent projects using natural gas have been approved with ammonia slip at 5.0 ppmvd, the 10 ppmvd level is reasonable for this source because the variability of RFG qualities require some

additional allowance for ammonia slip. SCR for controlling NO_x emissions is a proven control technology that is technologically feasible, cost-effective, and achieved in practice in a wide variety of applications.

Carbon Monoxide (CO)

The District BACT/TBACT Workbook specifies BACT Level 2 for CO, firing natural gas, for a Gas Turbine with a power rating ≥ 40 MW, as CO emissions ≤ 4.0 ppmvd @ 15% O₂, achieved through the use of an oxidation catalyst. CO emissions are also minimized through the use of good combustion practices. BACT Level 1 has not been determined for this source category.

The District has determined that BACT Level 2 for the Gas Turbine firing natural gas with the HRSG Duct Burners firing refinery fuel gas is 6 ppmvd @ 15% O₂. BACT Level 1 has not been determined. This determination is based on the Valero Cogeneration project permitted in 2001 (Application No. 2488 and 2695).

The CO emissions from a Gas Turbine fired on natural gas or LPG and the duct burners fired on RFG would be reduced through the use of an oxidation catalyst to a CO concentration level not to exceed 6.0 ppmvd @ 15% O₂, averaged over any consecutive three-hour period.

In summary, achieved in practice BACT for CO is deemed to be 6.0 ppmvd CO @15% O₂, averaged over any consecutive three-hour period, for the combined exhaust from the Gas Turbine and HRSG Duct Burners during all modes of operation, except startup and shutdown. Chevron will achieve compliance with this limit through the use of good combustion practices and CO Oxidation Catalyst. Furthermore, the Renewal Project's new Cogeneration Unit will be equipped with a CO and O₂ CEM system.

Precursor Organic Compounds (POC)

The District BACT/TBACT Workbook specifies BACT Level 2 for POC, on natural gas, for a Gas Turbine with a power rating ≥ 40 MW, as POC emissions ≤ 2.0 ppmvd @ 15% O₂, achieved through the use of an oxidation catalyst or efficient Dry Low-NO_x Combustors. BACT Level 1 has not been determined. The POC emissions from the Renewal Project Gas Turbine firing natural gas, or a combination of natural gas and LPG, and the HRSG Duct Burners firing RFG, or a combination of RFG and natural gas will be reduced through good combustion practice and the use of an oxidation catalyst to a level not to exceed 2.0 ppmvd POC @ 15% O₂, based on a District-approved source test. This control technology represents BACT for this cogeneration project.

In order to demonstrate compliance with both the POC and PM₁₀ emission estimates, Chevron must conduct an initial source test within 120 days of startup. The POC emission concentration limit is 2.0 ppmvd @ 15% O₂, based on a District-approved source test. After the initial source test, Chevron must conduct three quarterly tests followed by two semi-annual tests, and annual source tests thereafter. The permit conditions have been written to allow the District to require more frequent source testing if any of the test results are greater than or equal to 90% of an emissions estimate or limit.

Sulfur Dioxide (SO₂)

The proposed Cogeneration Unit (S-4473, S-4474) would have the gas turbine fired on natural gas or a combination of natural gas with LPG, and the HRSG Duct Burners fired on RFG/natural gas. The District BACT/TBACT Workbook specifies BACT for SO₂ emissions as the use of PUC quality natural gas with sulfur content not to exceed 1.0 grain/100 scf (Grains are equal to 1/7000 of a pound). A case-by-case BACT analysis was performed. To control SO₂ emissions, the sulfur levels in the RFG would need to be at the lowest achievable level.

The District has determined that in order to avoid triggering BACT for SO₂ emissions increases from existing combustion sources firing on RFG, permit conditions limiting the sulfur levels in the RFG to baseline levels for both H₂S and TS are required. The baseline RFG concentrations are 30.85 ppmvd TS and 18.83 ppmvd H₂S (for any consecutive 365-day period). Based on records provided by Chevron, the Refinery currently routinely achieves these sulfur levels in its RFG. Both blending with natural gas and scrubbing to maintain this level on an ongoing basis are feasible.

The District will also impose a permit condition consistent with other BACT determinations made at other Bay Area refineries with the maximum daily limit for the RFG of a TS concentration at 100 ppmvd (averaged over any calendar day). The maximum daily limit for the RFG is an H₂S concentration of 50 ppmvd (averaged over a calendar day).

The Renewal Project's proposal to handle crude slates with increased sulfur levels require these RFG conditions since the RFG may otherwise experience an increase in sulfur, which would result in increased SO₂ emissions from all combustion sources using RFG. Instead of accepting limits on the total fuel flow at each drum, Chevron requested a limit on the total SO₂ emissions (approximately 53 tons/year) from the RFG system plus the Cogeneration Unit Gas Turbine and Heat Recovery Steam Generator. The mass emissions limit of approximately 49 tons per year of SO₂ combined with the concentration limits creates an implied fuel flow limit.

Particulate Matter (PM₁₀)

The proposed Cogeneration Unit (S-4473, S-4474) would have the Gas Turbine firing natural gas, or a combination of natural gas and liquefied petroleum gas (LPG), and the HRSG Duct Burners firing RFG or a combination of RFG and natural gas. According to the District BACT/TBACT Workbook, PM₁₀ BACT Level 2 for combustion sources, such as the Cogeneration Unit, is firing California Public Utilities Commission (PUC)-quality natural gas with sulfur content not to exceed 1.0 grain/100 scf. PM₁₀ BACT Level 1 has not been determined. The District BACT/TBACT Workbook does not specify a typical technology or PM₁₀ emission limits for this source category. PM₁₀ emissions from the Cogeneration Unit are subject to BACT requirements, and the District reviewed available emissions data to set a permit limit with a reasonable compliance margin.

The District has determined that the BACT Level 2 for the Gas Turbine firing natural gas or a combination of RFG and natural gas with the HRSG Duct Burners firing RFG or a combination

of RFG and natural gas is 0.00574 lb/MMBtu. This BACT determination is based on the Valero Cogeneration project permitted in 2001 (Application Nos. 2488 and 2695), using multiple fuels including RFG and/or natural gas or a combination of the two fuels. Chevron proposes to fire the Refinery's Gas Turbine and Duct Burners on similar multi-fuels. The Valero Cogeneration project has a permit limit of 4.65 lb/hour and a maximum firing rate of 810 MMBtu/hr for the Gas Turbine and HRSG Duct Burners. These values correspond to the 0.00574 lb/MMBtu limit, which is achieved in practice. Compliance with the PM₁₀ emission limit has been consistently demonstrated since 2003 through a District-approved quarterly source testing requirement on the Valero Cogen Gas Turbine. PM₁₀ emissions from the Renewal Project would be controlled by using clean-burning natural gas/treated (low-sulfur) RFG and good combustion practices.

A District permit condition would include a caveat that allows the District to re-review this PM₁₀ limit if source testing demonstrates that the limit cannot be achieved while operating with a fuel selection that satisfies a BACT-level of control. Moreover, the source test policy for combustion sources utilizing SCR allows for the subtraction of ammonium sulfates, which creates a compliance margin. The District anticipates that Chevron will be able to achieve compliance with the PM₁₀ emissions that Valero achieves. However, Chevron will accept permit conditions on the sulfur level in the RFG and be required to conduct source tests to demonstrate compliance with short-term and long-term emission limits.

In addition, the CO CEM will be a good indicator of good combustion practice at each source. Low CO emissions generally correspond to low particulate emissions since each is a product of incomplete combustion.

BACT for Modified Sulfur Recovery Units

As part of the Renewal Project, Chevron is modifying three existing Sulfur Recovery Units S-4227, S-4228, and S-4229 that use Wellman-Lord Tail Gas Units. Each SRU has a corresponding Stack Gas Heater S-4436, S-4437, and S-4438. This BACT determination is for each SRU and Stack Gas Heater combined.

For this application, BACT for the SRU will be triggered for SO₂, NO_x. BACT is not triggered for PM₁₀, CO, or POC. Per Regulation 2-2-301 BACT is required for modified sources with an increase in emissions which have the potential to emit 10 pounds or more per highest day. The requested increase in capacity and/or production rate from all three SRUs from the currently permitted level and the increase in both daily and annual SO₂ emissions make these SRUs modified sources per Regulation 2-1-234.1. PM₁₀ emissions from SRU 1 and SRU 2 and POC emissions from all three SRUs would not exceed 10 pounds per highest day and are not subject to BACT. Chevron has accepted permit conditions to demonstrate that emissions of these pollutants from these sources would remain below 10 pounds per highest day. PM₁₀ emissions from SRU 3 will be greater than 10 pounds per highest day, however there will be no increase in either the daily or annual PM₁₀ emissions from SRU 3. The reduction in PM₁₀ emissions from the three SRUs is due to the installation of the Wet ESPs. Chevron's proposed SRU modifications also include a significant increase in flowrate, which impacts both daily and annual emissions.

The last BACT determination for an SRU made by the District was in 2007 for the ConocoPhillips Clean Fuels Expansion Project. Prior to that, the last BACT determination made by the District for an SRU was in Application 8407 for the Shell Martinez Refinery in 1993. Both of these SRUs have SCOT Tail Gas Units. A summary of the SRU BACT determination for ConocoPhillips follows:

SO₂: 50 ppmv @ 0% O₂ averaged over any consecutive 24-hours (based on Shell Application 8407, 1993 BACT determination)

NO_x: 42.2 ppmv @ 7% O₂ one-hour averaging (based on ConocoPhillips Ferndale Refinery)

CO: 75 ppmv @ 7% O₂ one-hour averaging (based on ConocoPhillips Ferndale Refinery)

SO₂ BACT:

The SO₂ BACT determination for Chevron's SRUs included both an SO₂ emissions limit and technological control measures. This approach was taken since limited information was available on Wellman-Lord SRUs, and the District will keep the limits similar to the known performance of SCOT units. Chevron suggested some of the technological methods of operation and equipment improvements that would result in reductions of SO₂ emissions.

- 50.0 ppmv SO₂ @ 0% O₂, averaged over any calendar day as determined by an SO₂ CEM. (Based on the EPA BACT/LAER Clearinghouse/BAAQMD BACT/TBACT Workbook).
- Reduce H₂S bypassing at the Thermal Oxidizer: Performance tests have detected some H₂S bypassing and breakthrough from the Thermal Oxidizers, which contributes to SO₂ formed in the stack heater. To address this (and CO destruction), Chevron will modify the Thermal Oxidizer internals for better mixing, improve the control of excess O₂ and, if deemed necessary or beneficial by the District based on computational fluid dynamics (CFD) modeling conducted by Chevron, relocate the sulfur pit vent line to the tail gas inlet line. Chevron will be using an engineering firm to perform computational fluid dynamic analysis (flow modeling) of the Thermal Oxidizers to assist in optimizing the performance.
- Improve scrubbing of SO₂: The operation of the SO₂ Absorbers will be improved by increasing the makeup sodium sulfite rate, and upgrading the piping and controls and caustic make-up rate to meet the SO₂ concentration limit specified above. The controls for caustic makeup will also be upgraded for more stable operation.
- Reduce the number and size of upsets caused by hydrocarbon in the acid gas feed to the SRUs: The new 6H₂S Recovery Unit, which generates the largest acid gas feed stream, will follow Best Practice design guidelines for hydrocarbon removal. This includes sizing and internal design of the amine flash drum and carbon filtration of the amine. Improvements will be made in vent gas cooling and separation at the FCC feed hydrotreater by added/upgraded coolers in three locations. This will reduce C3 and C4 carryover into vent gas and acid gas. The PSA tail gas, which currently goes to the RLOP Gas Recovery Unit, will be re-routed to the Hydrogen Plant feed or the refinery

fuel gas system. This will reduce the GRU feedrate and improve cooling and separation at the RLOP GRU.

NO_x BACT:

The NO_x BACT determination for the SRUs presented several issues, the main being the establishment of a short-term limit. As mentioned above, both ConocoPhillips Ferndale and Rodeo have had NO_x BACT determinations made on their SRUs. Arizona Clean Fuels Yuma LLC also had a NO_x BACT determination for a new SRU done in 2005. The Arizona permit proposed a NO_x limit of 0.06 lb/MMBtu. None of these sources utilize the Wellman-Lord tail gas process used on the Chevron SRUs.

BACT determinations are often characterized as either standard or technology driven. This BACT determination is clearly technology driven, as opposed to standard driven, since at the time of issuance it was difficult to determine the extent of the reductions that will be achieved through the use of this technology. A summary of the requirements to satisfy NO_x BACT for each SRU follows:

- 50 ppmv NO_x @ 0% O₂, 3-hour average (condition to install CEM consistent with El Segundo Chevron Refinery SRUs). After reviewing 6 months worth of NO_x CEM data from the El Segundo Refinery, which also uses a Wellman-Lord Tail Gas Unit, it was determined that the highest 3-hour average concentration was 54 ppmv @ 0% O₂, from the lowest NO_x emitting SRU, which is equipped with its original burners from the 1970's. Based on discussions with a burner manufacturer, the District believes that, with the retrofit of ultra Low-NO_x Burners and other technologies listed below, the Thermal Oxidizers and stack gas heaters can achieve NO_x emissions below the 50 ppmv level on a continuous basis.
- Installation of pre-approved ultra Low-NO_x Burners and fuel induced recirculation (FIR) at both the Thermal Oxidizers and Stack Gas Heaters.
- Require the use of oxygen enrichment when operating at levels above original design capacities since this is how Chevron asserts it will achieve no emissions increases beyond original design levels (150 long tons per day (LTD), 150 LTD, 300 LTD). Discussions with the SRU vendor supports Chevron's assertion.
- Installation of NO_x CEMs in order to demonstrate compliance with short-term limits and annual mass emissions limits when used in conjunction with a flowmeter.
- Installation of a flowmeter. The flowmeter shall be installed in order to demonstrate compliance with the mass emissions limits from each SRU.

CO BACT ANALYSIS:

The District determined that BACT for CO was not triggered for each SRU since Chevron agreed to accept permit conditions limiting both daily and annual CO emissions at current operating levels. The daily CO emission limits correspond with the District's estimated actual daily baseline CO emissions for each SRU. The annual CO emission limits will be less than the current estimated annual CO emissions for each SRU.

In order to prevent CO BACT from being triggered, Chevron has agreed to the following requirements for each SRU as follows:

- New (ultra) Low-NO_x Burners with fuel-induced recirculation (FIR) at both the Thermal Oxidizers and Stack Gas Heaters, improved combustion/mixing efficiency, and increased Thermal Oxidizer temperature (to 1,400 F).
- The following daily and annual CO emission limits at each SRU.

SRU #1	222.72 lb/day	28.08 TPY (12 month rolling average)
SRU #2	173.52 lb/day	28.08 TPY (12 month rolling average)
SRU #3	325.44 lb/day	57.64 TPY (12 month rolling average)
- Minimum temperature set point at the Thermal Oxidizer of 1,400 F.
- Install CO CEM and flowmeter in order to demonstrate compliance with daily and annual CO emission limits at each SRU.

Chevron requested annual emissions levels that correspond to lower throughput levels and lower concentration levels than what is currently being requested on the latest data form submittal. There is a direct link between throughput and emissions and the District's emissions inventory relies on throughput in order to determine emissions per throughput for this source category. However, since Chevron will be accepting permit conditions that require both a CO CEM and a flow monitoring device these annual emissions limits shall be enforceable and will assist the District in determining the allowable annual throughput conditions that correspond to compliance with all emissions limits on each SRU.

The permit conditions are written in a manner that allows the District to finalize the throughput condition limits after compliance with all emissions limits is demonstrated. This approach was taken since there is a relationship between throughput and emissions for the three SRUs. Chevron has requested that the District use emissions estimates that correspond to lower annual throughput levels than the levels requested in the permit application. For example, Chevron requested that the Renewal Project emissions estimates be based on the flow rates that corresponds to 225 long tons (LT)/day, 225 LT/day, and 450 LT/day. Chevron recently requested SRU throughputs of 345 LT/day, 345 LT/day, and 570 LT/day. The District determined that an approach to handle Chevron's request is to use compliance with the emissions estimates to determine the corresponding allowable throughput levels. The District has determined that both throughput and emissions limits are warranted for this source category.

The SRUs' baseline CO emissions were not established by using CEM data since the three SRUs currently do not have CO CEMs. The baseline was determined using CO source test data from each of the SRUs. The CO baseline used was not adjusted downward for RACT since it was decided that there was no RACT adjustment to be made for CO emissions from the combined Thermal Oxidizer and Stack Gas Heater. The District was unable to locate any regulations in place that specifically limit the CO emissions from a Wellman-Lord Tail Gas Unit. The analysis was limited to reviewing only Wellman-Lord units operating at 1,350 F. The District staff was unable to accurately determine the reduction in CO emissions caused by raising the Thermal Oxidizer temperature from 1,350 F to 1,400 F and the reductions in CO emissions associated with upgrading the burners from a straight pipe with a pilot to ultra low-NO_x burner technology.

SRU CO emissions are abated by a Thermal Oxidizer. Source tests submitted by Chevron to the District demonstrate that increasing the Thermal Oxidizer temperature results in significant reductions in CO emissions. Chevron stated that historically the Thermal Oxidizer set point was 1,350 F. Both the increased Thermal Oxidizer set point temperature of 1,400 F and the CO CEM with flow monitoring device will help ensure that each modified SRU will comply with both the daily and annual CO emissions limits.

PM₁₀ BACT:

Each SRU will be abated by a dedicated new Wet ESP, which would ensure that PM₁₀ emissions do not increase above the baseline emissions. Wet ESPs typically reduce the PM₁₀ emissions by 90% or greater by weight. Although SRU 3's potential to emit is greater than 10 pounds per highest day, SRU 3 (S-4229) does not trigger BACT since its PM₁₀ emissions will not be increasing. The District is unaware of any Wellman-Lord SRUs being equipped with Wet ESPs. All three SRUs (S-4227 to S-4229) will be abated by Wet ESPs in order to control both PM₁₀ and H₂SO₄ emissions from the SRUs. The installation of the Wet ESPs prevented these three SRUs from triggering BACT.

The District permit conditions have established placeholder-type parametric permit conditions that will ensure compliance with emissions reductions associated with the proper operation of the Wet ESPs. These parameter placeholders were selected based on discussions with Wet ESP vendors and on CARB compliance assistance program reference materials. Some of the identified parameters may include: inlet water flow rate (in gpm), transformer rectifier (TR) set secondary current readings (in milliamps), maximum inlet temperature, and pH of the water system. The District also left an opening to include any new parameters identified by either the Wet ESP manufacturer or the District. Short-term emissions limits for both PM₁₀ and H₂SO₄ will be monitored through periodic source testing. The source test results will be used to demonstrate compliance with annual emission estimates.

POC BACT:

POC emissions do not trigger BACT since the highest days emissions estimate is less than 10 pounds of POC per day. The required increased Thermal Oxidizer temperature of 1,400 F will help to control any POC emissions increase. The new Low-NO_x Burners equipped with fuel induced recirculation (FIR) in both the Thermal Oxidizers and the Stack Gas Heaters of each of the SRUs should also minimize POC emissions due to better mixing and combustion.

Offsets:

Project emission increases from new/modified sources are presented in Table 2. The emission increases will be offset using the appropriate offset ratio per District Regulation 2-2. Chevron intends to use a combination of contemporaneous emission reductions and banked Emission Reduction Credits (ERCs). Contemporaneous emission reductions maintain net emissions below federal major NSR and PSD thresholds. A combination of existing banked ERCs and

contemporaneous emissions reductions would be used to offset any emissions increase associated with the Renewal Project.

Contemporaneous Emission Reductions

Chevron originally requested that the District use the POC emissions factor (0.003 lb/MMBtu) for combustion sources to be shut down that is used in condition #469 Richmond Lube Oil Project (RLOP)/Bubble. In Chevron's efforts to not exceed either the CEQA significance thresholds or PSD triggers, Chevron later requested that the District use the current EPA AP-42 combustion POC emissions factor (0.0054 lb/MMBtu) for the combustion sources to be shutdown. District Regulation 2-2-605.4 describes the process for establishing the baseline for a fully offset source stating that the baseline throughput and emission rate shall be based on levels allowed by the permit condition. Since the sources involved are included in a bubble, the "levels allowed by the permit" are the bubble limit. Providing the incremental offsets for the shutdown sources based on the difference between the emission factors assures that credits are not provided for emissions that have not been previously offset at the correct ratios. The District determined that for the combustion sources that are being shutdown as part of the Renewal Project, Chevron would provide POC offsets at an offset ratio of 1.15 to 1.0 to account for the difference in the two emissions factors.

Contemporaneous emission reductions can be used without a RACT adjustment for both CEQA and PSD purposes. The definition of Emission Reduction Credit per District Regulation 2-2-201.3 clearly states that for PSD purposes emissions are not RACT adjusted. A majority of the contemporaneous emission reductions for this project come from the shutdown of several furnaces.

All emissions reductions are subject to District Regulation 2-2-605 per many sections including: 2-2-201, 302, 303, and 606. District Regulation 2-2-243 defines RACT and the definition is broken into two parts. The first part of the definition discusses sources that would continue to operate (i.e. modified sources) and the second part pertains to closures or shutdown sources. The main difference is that RACT for sources continuing to operate is the lowest achievable emission limit but takes into account the "specific source" whereas for shutdowns RACT is the lowest emission limit that can be achieved by the application of control technology to similar, but not necessarily identical categories of sources, taking into account technological feasibility and cost-effectiveness of the application of the control technology to the category of sources only and not to the shut-down source. This ensures that ERCs given for shutdowns is fairly distributed since it uses the lowest emission rate achievable by similar but not necessarily identical categories of sources and will not penalize the low emitters.

General Requirements

Pursuant to District Regulation 2-2-302, federally enforceable emission offsets are required for POC and NO_x (as NO₂) emission increases from permitted sources at facilities, which will emit 10 tons per year or more on a pollutant-specific basis. For facilities that will emit more than 35 tons per year of NO_x (as NO₂), offsets must be provided by the applicant/permittee at a ratio of 1.15 to 1.0. Pursuant to Regulation 2-2-302.2, POC offsets may be used to offset emission

increases of NO_x.

Pursuant to District Regulation 2-2-303, emission offsets are required (at a ratio of 1.0:1.0) for PM₁₀ and/or SO₂ emission increases from new/modified sources at a Major Facility if emissions of these pollutants will increase by more than 1.0 tons per year. Pursuant to Regulation 2-2-303.1, emission reduction credits of nitrogen oxides or sulfur dioxide may be used to offset PM₁₀ emission increases at offset ratios determined by the District's Air Pollution Control Officer (APCO) to result in a net air quality benefit. This determination is based upon a case-by-case analysis that includes modeling, public notice, opportunity for public comment, and US EPA concurrence.

In the case of POC and NO_x offsets, District regulations do not require consideration of the location of the source of the emission reduction credits relative to the location of the proposed emission increases that will be offset. Chevron will provide offsets for this Project exclusively from offsets created at the Refinery.

Timing for Provision of Offsets

Pursuant to District Regulation 2-2-311, the applicant must provide the required valid emission reduction credits to mitigate the emission increases for the proposed project prior to the issuance of the Authority to Construct. However, District Regulation 2-2-421, allows the applicant to defer providing the offsets until the time of the annual permit renewal provided the applicant has valid Banking Certificates adequate to cover the offset obligation and that the facility does not have a cumulative increase greater than 15 tons per year for the pollutant or pollutants subject to the offset requirement(s). Chevron has provided emissions estimates and Banking Certificate inventories that show these provisions are met.

Offset Requirements by Pollutant

The quantity of offsets required is summarized in Table 2. Chevron has proposed to fully offset the cumulative increases requiring emission reduction credits from this project using its currently banked emission reduction credits. This approach assists the District expediting the issuance of the Authority to Construct since a banking/offsetting analysis, including any necessary RACT adjustments, will not be required prior to issuance. Chevron is planning to apply to bank any remaining reductions from the shutdown equipment. However, both the PSD netting and CEQA analysis used some portion of any available credits consistent with Regulation 2-4-303.2.2, and all emission reduction credits from these shutdowns must comply with the requirements in Regulations 2-4 and 2-2-605.

POC Offsets

Because the Refinery emissions are greater than 35 tons of POC per year, the POC emissions must be offset at a ratio of 1.15 to 1.0 pursuant to District Regulation 2-2-302. The cumulative increase in POC emissions from the Renewal Project is 69.34 tons per year (tpy); using an offset ratio of 1.15:1.0 requires 79.74 tpy of POC offsets.

NO_x Offsets

Because the Refinery emissions are greater than 35 tons per year of NO_x from permitted sources, Chevron must provide ERCs of NO_x at a ratio of 1.15 to 1.0 pursuant to District Regulation 2-2-302. Pursuant to District Regulation 2-2-302.2, Chevron has the option to provide POC ERCs to offset the proposed NO_x emission increases at a ratio of 1.15 to 1.0. The cumulative increase in NO_x emissions from the Renewal Project is 141.20 tpy; using an offset ratio of 1.15:1.0 requires 162.38 tpy of NO_x offsets.

PM₁₀ Offsets

The cumulative increase in PM₁₀ emissions from the Renewal Project is 47.95 tpy; using an offset ratio per District Regulation 2-2-303 of 1.0:1.0 requires 47.95 tpy of PM₁₀ emission reduction credits.

SO₂ Offsets

The cumulative increase in SO₂ emissions from the Renewal Project is 58.50 tpy; using an offset ratio per District Regulation 2-2-303 of 1.0:1.0 requires 58.50 tpy of SO₂ emission reduction credits.

PREVENTION OF SIGNIFICANT DETERIORATION AIR QUALITY IMPACT ANALYSIS

Pursuant to District Regulation 2-2-414.1, Chevron was not required to submit a modeling analysis that estimates the air quality impacts of the Renewal Project.

PSD is not triggered by this application since the net emissions from the Renewal Project do not exceed the PSD trigger levels in Regulation 2, Rule 2. The District's PSD Agreement with EPA Region IX requires that EPA be notified of projects that net out of PSD. A letter informing the EPA that this project will net out of PSD will be sent to EPA Region IX after the Authority to Construct has been issued.

HEALTH RISK SCREENING ANALYSIS

Pursuant to the District Regulation 2, Rule 5, the District conducted a Health Risk Screening Analysis (HRSA) to determine the potential impact on public health resulting from the emissions of toxic air contaminants (TAC) from the Renewal Project's new/modified sources. The detailed HRSA results, health-risk-weighted TAC emissions input, and methodology used are presented in Appendix C of this report. Note that the District Regulation 2-5 HRSA addresses only the increase in health risks from new/modified sources, and not the reductions in health risks associated with the shut-down of existing sources.

Results:

Results of the HRSA indicate that, for this Project, the maximum incremental cancer risk is

estimated at 2 in a million, the chronic hazard index is 0.3, and the acute hazard index is 1.0. In accordance with District Regulation 2, Rule 5, these risk levels are considered acceptable. None of the individual source emissions result in a cancer risk that is greater than one in a million, nor a chronic hazard that is greater than 0.20. At these risk levels, none of the sources trigger the requirement for TBACT (Best Available Control Technology for Toxics). In addition, the Project, with a 30-day maximum lead concentration of $0.0022 \mu\text{g}/\text{m}^3$, is approvable per the ARB Risk Management Guidelines for New, Modified and Existing Sources of Lead.

OTHER APPLICABLE DISTRICT RULES AND REGULATIONS

Regulation 1, Section 301: Public Nuisance

The proposed project's sources of air contaminants are not expected to cause injury, detriment, nuisance, or annoyance to any considerable number of persons with respect to any impacts resulting from the emissions regulated by the District.

Regulation 1, Section 521, 522, 523: CEMS, Parametric Monitoring

The District will require NO_x and CO CEMs for all of the Renewal Project furnaces and cogeneration sources. Additionally, the SRUs will be equipped with SO_2 , NO_x , and CO CEMs. These sources will be subject to the continuous emission monitoring requirements identified in District Regulation 1, Sections 520.4 and 522.

The District will also require many Renewal Project sources to monitor key process parameters that demonstrate compliance with permit limits, such as ammonia injection rate on units that are abated by SCR units. The sources required to install instruments to monitor process information that would be used to demonstrate compliance with permit limits are subject to the parametric monitoring requirements in District Regulation 1-523.

Regulation 2, Rule 1, Sections 301 and 302: Authority to Construct and Permit to Operate

Pursuant to District Regulation 2-1-301 and 2-1-302, Chevron has submitted an application to the District to obtain an Authority to Construct and Permit to Operate for the Renewal Project proposed sources.

Regulation 2, Rule 1, Sections 426: CEQA-Related Information Requirements

As the Lead Agency for the proposed Renewal Project, the City of Richmond is responsible for compliance with CEQA requirements. The draft and final EIR issued by the City for the Project meet the CEQA-information requirements of District Regulation 2-1-426.

Regulation 2, Rule 6: Major Facility Review

Pursuant to District Regulation 2-6-404.1, the owner/operator of the Refinery must submit an application to the District for a major facility review permit modifications prior to commencing operation of the proposed new sources in accordance with District Regulation 2-6-404.3.

Regulation 2, Rule 7: Acid Rain

S-4473 gas turbine and S-4474 heat recovery steam generator with duct burners may be subject to portions of Title IV of the federal Clean Air Act. The requirements of the Acid Rain Program are outlined in 40 Code of Federal Regulations (CFR) Part 72. The specifications for the type and operation of CEMs for pollutants that contribute to the formation of acid rain are given in 40 CFR Part 75.

District Regulation 2, Rule 7 incorporates by reference the provisions of 40 CFR Part 72. Pursuant to 40 CFR Part 72.30(b)(2)(ii), depending on the amount of power sold to the commercial grid, the cogeneration unit may become subject to the Acid Rain permit program. If the Cogeneration unit becomes subject to the Acid Rain permit program provisions, then Chevron must submit an Acid Rain permit application to the District at least 24 months prior to the date on which the unit commences operation. Pursuant to 40 CFR Part 72.2, “commence operation” includes the start-up of the unit’s combustion chamber.

Provisions in §§72.2 through 72.6, and §§72.10 through 72.13 may apply to this facility. The new cogeneration unit is expected to comply with the applicable sections of 40 CFR Part 72, which will be reviewed in the future Acid Rain permit application.

Regulation 6, Rule 1: Particulate Matter and Visible Emissions – General Requirements

The Renewal Project sources are expected to comply with District Regulation 6-1, including Sections 301: Ringelmann No. 1 Limitation, 302: Opacity Limitation, with visible emissions not to exceed 20% opacity, and Section 310: Particulate Weight Limitation, with particulate matter emissions of less than 0.15 grains per dry standard cubic foot (dscf) of exhaust gas volume.

All Renewal Project combustion sources are fueled with gaseous fuels and are expected to comply with the grain loading limit indicated in District Regulation 6-1-310.

The S-4465 Hydrogen Plant Cooling Tower, is also expected to comply with the requirements of Regulation 6-1 since the Cooling Tower PM₁₀ emissions are controlled by the use of a Cooling Water Tower equipped with drift eliminators with a guaranteed drift rate of 0.0005%.

PM₁₀ emissions associated with the construction of the Renewal Project sources are exempt from District permit requirements but are subject to Regulation 6-1. The EIR for the project includes mitigation measures for construction activities that would require the use of water and/or chemical dust suppressants to minimize PM₁₀ emissions and prevent visible particulate emissions.

The Renewal Project turbines, heat recovery steam generators, process heaters, and combustion sources all burn gaseous fuels and are expected to comply with District Regulation 6-1. These sources are subject to Regulations 6-1-301, 6-1-305, and 6-1-310.3. Regulation 6-1-301 is a requirement that visible emissions may not exceed 1.0 Ringelmann for more than 3 minutes/hour. Regulation 6-1-305 is a requirement that a unit may not emit visible particles that

fall outside of the facility's property. Regulation 6-1-310.3 is the grain-loading limit for heat transfer operations of 0.15 grains filterable particulate/dscf @ 6% O₂. The sources burn gaseous fuels and are expected to comply with these requirements.

The SRUs are subject to District Regulations 6-1-301, 6-1-305, 6-1-310, 6-1-311, 6-1-330, and 6-1-501. Regulations 6-1-301 and 6-1-305 were described in the paragraph above. Regulation 6-1-310 is the general grain-loading limit of 0.15 grains filterable particulate/dscf. Regulation 6-1-311 is the process weight limit. Regulation 6-1-330 has a limit of 0.08 grains/dscf of SO₃ or H₂SO₄, or both, expressed as 100% H₂SO₄, exceeding 0.08 grains/dscf of exhaust gas volume. "Filterable particulate" means particulate as measured by District Source Test Method ST-15, Particulate.

The PM₁₀ emissions from each of the SRUs will be abated by Wet ESPs. Therefore the SRUs are expected to comply with Regulations 6-1-301, 6-1-305, 6-1-311, and 6-1-330. The SRUs are not generally sources of visible emissions and testing for the sulfuric acid mist standard in District Regulation 6-1-330 is feasible and will be performed on a periodic basis. It is not feasible to test the existing units for the filterable particulate standards in Regulations 6-1-310 and 6-1-311 at this time because the SRUs do not have the required ports for source testing. The new unit will have the ports and will be tested on an annual basis.

In order to demonstrate compliance with PM₁₀ emission estimates, Chevron must conduct an initial source test within 120 days of startup. After the initial source test, Chevron must conduct three quarterly tests followed by two semi-annual tests and annual source tests thereafter. The permit conditions have been written to allow the District to require more frequent source testing if any of the results are either greater than or equal to 90% of an emissions estimate or limit.

The magnitude of the limit in Section 6-1-311 is determined by the process weight rate of the unit. The facility will be required to perform an initial and annual source test to assure compliance with Sections 6-1-310, 6-1-311, and 6-1-330. At this time, the filterable particulate concentration and mass emissions will be determined. The SRUs are expected to comply with Sections 6-1-310 and 6-1-311, especially because controlled sulfur recovery units generally do not have visible emissions, which are indicators of high particulate emissions.

Therefore, the SRUs are expected to comply with all of the Regulation 6-1 standards.

Regulation 7: Odorous Substances

The purpose of Regulation 7 is the general control of odorous compounds. All of the Renewal Project sources are expected to comply with Regulation 7. Ammonia is mentioned specifically in Regulation 7. H₂S is not specifically mentioned in Regulation 7 other than to direct the reader to Regulation 9, Rule 2. However, Regulation 7-301 and 302 have a general limit on odorous substances and a limit on odorous substances at or beyond the property line that may apply to H₂S emissions.

Ammonia

Regulation 7-302 prohibits the discharge of odorous substances, which remain odorous beyond the facility property line after dilution with four parts odor-free air. Regulation 7-302 limits ammonia emissions to 5,000 ppmvd. Because the ammonia slip emissions from the proposed combustion sources equipped with SCR will be limited by permit condition to 10 ppmvd, the facility is expected to comply with the requirements of Regulation 7.

The Renewal Project includes process heaters with SCR and modifications to SRUs, which are sources of ammonia. Ammonia is used at process heaters with SCR for abatement of NO_x. SRUs burn ammonia that is concentrated in the sour gas. District Regulation 7-303 limits the concentration of ammonia from Type A emission points to 5,000 ppm. A Type A emission point is defined in District Regulation 1-230 as: "An emission point, having sufficiently regular geometry so that both flow volume and contaminant concentrations can be measured and where the nature and extent of air contaminants do not change substantially between a sampling point and the emission point." There is no correction for oxygen concentration. The heaters will comply because the heaters have a limit of 10 ppmv ammonia @ 3% oxygen. It is expected that the SRU will comply because tests for ammonia at the other SRUs have measured concentrations less than 10 ppm @ 15% O₂. The concentration of ammonia in the stacks of both source categories will be measured by source test after construction.

Regulation 8: Organic Compounds

The S-4473 Gas Turbine is exempt from District Regulation 8, Rule 2: "Miscellaneous Operations" per District Regulation 8-2-110 since natural gas and LPG will be fired exclusively at those sources.

The remaining Renewal Project combustion sources are fired on gaseous fuels and are expected to comply with the requirements of Regulation 8, Rule 2.

Cooling towers are exempt from this rule, in accordance with Section 8-2-114, if best modern practices are used. The District has determined best modern practices for cooling towers are as follows: daily visual inspection, water sampling and analysis for indicators of hydrocarbon leaks once per shift. Chevron will use best modern practices.

The use of solvents for cleaning and maintenance at the Renewal Project sources is expected to comply with District Regulation 8, Rule 4, "General Solvent and Surface Coating Operations," Section 302.1 by emitting less than 5 tons per year of volatile organic compounds.

Regulation 8, Rule 10: Process Vessel Depressurization

Process vessels contained in components of the Renewal Project (Hydrogen Plant, Continuous Catalytic Regenerative Reformer, and Hydrogen Purity Improvements) will be subject to Regulation 8, Rule 10. Section 301 of the rule requires that the emissions during depressurizing be controlled by an abatement device or the fuel gas system until the vessel is as close to atmospheric pressure as possible, but at least until the partial pressure of organic compounds in the vessel is less than 4.6 psig. Section 302 requires that no process vessel may be opened to the atmosphere unless the internal concentration of total organic compounds has been reduced prior

to release to the atmosphere to less than 10,000 ppmvd, with the following exception - vessels may be opened when the concentration of total organic compounds is 10,000 ppmvd or greater provided that the total number of such vessels opened with such concentration during any consecutive five year period does not exceed 10% of the total process vessel population, the organic compound emissions from the opening of these vessels does not exceed 15 pounds per day and the vessels are not opened on any day on which the APCO predicts an exceedance of a National Ambient Air Quality Standard for ozone or declares a Spare the Air Day. The Renewal Project sources that are subject to Regulation 8, Rule 10 are expected to comply with these requirements.

Regulation 8, Rule 18: Equipment Leaks

The Renewal Project fugitive components - valves, flanges, pumps, compressors, pressure relief devices - are subject to District Regulation 8, Rule 18. The rule has total organic leak limits of 100 ppmvd for valves and flanges, and 500 ppmvd for pumps, compressors, and pressure relief devices. These are "work-practice" standards. The facility is obligated to test the components for leaks on a periodic basis and to repair the leaks. A small percentage of non-repairable leaks are allowed until the next turnaround or five years, whichever is sooner. The facility has an inspection program for this regulation and is expected to comply with these standards for the new sources because the components will meet BACT, which was defined in Section 3.4 of this evaluation.

Regulation 8, Rule 28: Episodic Releases from Pressure Relief Devices at Petroleum Refineries and Chemical Plants

District Regulation 8, Rule 28 applies to pressure relief devices (PRD) installed on refinery equipment. Regulation 8-28-302 applies to PRDs on new or modified sources. It requires that these PRDs comply with all requirements of Regulation 2, Rule 2, including BACT. BACT Level 1 is currently a rupture disk with a vent to a fuel gas recovery system, furnace, or flare with a recovery/destruction efficiency of 98%. The District has determined that rupture disks may not be feasible where there are a high number of pressure cycles and high temperatures and would require additional maintenance since the rupture disks would have to be replaced/repared if a rupture occurs. The perceived advantage of the rupture disks is that it indicates whether there has been flow to the fuel gas recovery system. If an event occurs associated with flaring, knowing that the vessel was vented to the flare would aid in a causal analysis. District Regulation 12, Rule 11 monitoring and Refinery data will enable the District staff to determine whether venting of the vessel occurred by reviewing the pressure data available for all vessels.

Existing PRDs associated with the Renewal Project's modified process units are also subject to the standard. These PRDs will be subject to BACT Level 2, which is a vent to a fuel gas recovery system, furnace, or flare with a recovery/destruction efficiency of 98%.

The sulfur pits are not subject to Regulation 8, Rule 28, because Section 8-28-101 states that the rule applies to equipment handling gaseous organic compounds at petroleum refineries. The sulfur pits do not handle gaseous organic compounds.

Permit conditions with the BACT requirement will be added to these units. The Refinery is expected to comply with this requirement.

Regulation 9: Inorganic Gaseous Pollutants

Regulation 9, Rule 1: Sulfur Dioxide

Regulation 9, Rule 1 establishes emission limits for sulfur dioxide from all sources and applies to the combustion sources at this facility. Section 301 (Limitations on Ground Level Concentrations) prohibits emissions which would result in ground level SO₂ concentrations in excess of 0.5 ppmvd continuously for 3 consecutive minutes, 0.25 ppmvd averaged over 60 consecutive minutes, or 0.05 ppmvd averaged over 24 hours. Section 302 (General Emission Limitation) prohibits SO₂ emissions in excess of 300 ppmvd (dry). The Renewal Project sources are not expected to cause ground level SO₂ concentrations in excess of the limits specified in Regulation 9-1-301 and should comply with Section 302. The SO₂ emissions from combustion sources will be limited on a refinery-wide basis by permit limits on the refinery fuel gas system. The fuel gas system will be limited to: 50 ppmvd H₂S averaged over a calendar day, 18.83 ppmvd H₂S averaged over any consecutive 365 day period, 100 ppmvd total sulfur averaged over a calendar day, and to 30.85 ppmvd total sulfur over any consecutive 365 day period. It is anticipated that SO₂ emissions at the facility will be decreased due to the implementation of the Renewal Project.

The combustion sources and the modified SRUs are sources of SO₂ emissions. These sources are not subject to the 300-ppm limit in District Regulation 9-1-301 because the refinery complies with the exemption in Regulation 9-1-110. The exemption requires ground level monitoring and compliance with the ground level concentration limit.

The modified SRUs are subject to the limit of 250 ppmv SO₂, dry, at zero percent O₂, in Regulation 9-1-307. The sources will be subject to continuous monitoring by Regulations 1-520, 1-522, and 9-1-502, which will ensure compliance.

Regulation 9, Rule 2, Hydrogen Sulfide

The Refinery is subject to the requirements of District Regulation 9, Rule 2. The Refinery utilizes ground level monitoring of H₂S to ensure compliance with the ground level concentration limits of 0.06 ppmvd averaged over three consecutive minutes or 0.03 ppmvd averaged over any 60 consecutive minutes.

H₂S is very odorous and is one of the compounds generated by various pieces of equipment in the refinery. Most of the H₂S in the refinery is concentrated in sour gas streams that are sent to the SRUs, where H₂S is converted to elemental sulfur. The SRUs are not expected to be a significant source of H₂S because any residual H₂S that exits the SRU will be burned in a stack gas heater.

Many pieces of equipment that are included in the Renewal Project can be sources of fugitive H₂S. After the implementation of the Renewal Project, the Refinery is required to continue to

monitor for H₂S and demonstrate ongoing compliance with Regulation 9, Rule 2. Therefore, the facility is expected to comply with the requirement.

The Sulfur Loading Rack, will handle molten sulfur that contains less than 10 ppmw H₂S. Additionally, the tank and truck rack H₂S emissions will also be controlled by a scrubber.

The District maintains and operates three air monitoring stations that measure ambient H₂S levels in the vicinity of the Refinery located at: (1) Point Richmond, (2) Richmond - 7th Street, and (3) Rodeo. Chevron operates three H₂S ground level monitoring stations. Each is located on Refinery property on the perimeter of the Refinery. One is located at the Castro Street side of the Refinery (Castro Street), the second is located at the Gertrude Street side of the Refinery (Gertrude Street), and the third is located above the Refinery on the bluff where tanks are located (Golden Gate).

Also, Chevron maintains an H₂S monitoring system at the SRUs. This system detects ambient levels of H₂S and, when required, activates an alarm system, which indicates the location and concentration of leaks. When H₂S levels exceed 10 ppm, a panel low alarm sounds in the SRU control house for that location. If levels exceed 20 ppm, a second panel high alarm sounds. Each event activates a field warble horn and a Control Board alarm for initiation of appropriate operational emergency response.

The monitoring system consists of 19 Model S214 and one Model S4000T General Monitors Smart H₂S Sensor Units (Electrical Classification Class I, Division 1) that are strategically located throughout the SRU Complex at the Refinery. Sensor elements within each unit utilize continuous diffusion adsorption type metal oxide semiconductor (MOS) technology to detect H₂S. In 2002, all units were upgraded from Model Type ST200 to Model Type S214. One unit was upgraded to Model S4000T in 2006. MOS sensors elements have a typical lifespan of three to five years. Regardless, because the units are classified as safety devices, Chevron tests and calibrates each sensor element on a monthly schedule. Defective sensor elements, if any, are replaced accordingly.

Regulation 9, Rule 3: Nitrogen Oxides from Heat Transfer Operations

The Renewal Project combustion sources listed below will comply with the Regulation 9-3-303 NO_x limits by complying with more stringent permit limits. This rule only applies to heaters greater than 250 MMBtu/hour.

S-4471 Hydrogen Plant Train #1 Reformer Furnace, 950 MMBtu/hour maximum firing rate higher heating value (HHV), equipped with Low-NO_x Burners abated by **A-0302** Hydrogen Plant Train #1 Selective Catalytic Reduction (SCR) [Vented to **P-0302** Hydrogen Plant Train #1 Furnace Exhaust]

S-4472 Hydrogen Plant Train #2 Reformer Furnace, 950 MMBtu/hour maximum firing rate HHV, equipped with Low-NO_x Burners abated by **A-0303** Hydrogen Plant Train #2 SCR [Vented to **P-0303** Hydrogen Plant Train #2 Furnace Exhaust]

S-4474 3rd Cogeneration Heat Recovery Steam Generator (HRSG) equipped with Duct Burners, equipped with Low-NO_x Burners, 350 MMBtu/hr Duct Burner maximum firing rate HHV. Combined Gas Turbine and HRSG equipped with Duct Burners 860 MMBtu/hr firing rate (calendar day). Combined Gas Turbine and HRSG with Duct Burners 840 MMBtu/hr maximum firing rate (annual average)

S-4478 Reformer Furnace #2, 402 MMBtu/hour maximum firing rate HHV equipped with Low-NO_x Burners abated by **A-0309** SCR

Regulation 9, Rule 7: Nitrogen Oxides and Carbon Monoxide from Industrial, Institutional, and Commercial Boilers, Steam Generators, and Process Heaters

The proposed Renewal Project Heat Recovery Steam Generators are exempt from the standards of Regulation 9, Rule 7, Section 301, which limits NO_x emissions to 30 ppmvd dry @ 3% O₂ and CO emissions to 400 ppmvd dry @ 3% O₂ per Regulation 9-7-110.5.

Regulation 9, Rule 9, Nitrogen Oxides from Stationary Gas Turbines

The proposed combustion Gas Turbine S-4473 will be limited by permit condition to NO_x emissions of 2.5 ppmvd (1-hour average) or 2.0 ppmvd (3-hour average) @ 15% O₂. The Turbine will therefore comply with the less stringent District Regulation 9-9-301.3 NO_x limitation of 9 ppmvd @ 15% O₂.

Regulation 9, Rule 10, Nitrogen Oxides and Carbon Monoxide from Boilers, Steam Generators and Process Heaters in Petroleum Refineries

All new and/or modified process heaters will be subject to current BACT limits for NO_x and CO, which are more stringent, instead of the Regulation 9, Rule 10 limits, which apply to existing process heaters.

Regulation 10: Standards of Performance for New Stationary Sources

District Regulation 10 incorporates by reference the provisions of Title 40 CFR Part 60. The applicable subparts of 40 CFR Part 60 include Subpart A, "General Provisions" and Subpart KKKK, "Standards of Performance for Stationary Combustion Turbines." Subpart KKKK exempts sources subject to it from Subparts Da, Db, Dc, and GG. The proposed Gas Turbines and Heat Recovery Steam Generators comply with all applicable standards and limits prescribed by these regulations. The applicable emission limitations are summarized in Table 8 below:

Table 8			
Source	Requirement	Emission Limitation	Compliance Verification
Gas Turbine and HRSG with Duct Burners S-4473, S-4474	Subpart KKKK	25 ppm NO _x at 15% oxygen on natural gas	Sources limited by permit condition to 2.5 ppmvd NO _x averaged over any 1-hour at 15% O ₂ , dry and 2.0 ppmvd NO _x averaged over any 3-hour period @ 15% O ₂
		74 ppm NO _x at 15% oxygen on other fuels other than natural gas	Sources limited by permit condition to 2.5 ppmvd NO _x averaged over any 1-hour at 15% O ₂ , dry and 2.0 ppmvd NO _x averaged over any 3-hour period @ 15% O ₂
		0.06 lb SO ₂ /MMBtu heat input	Project maximum SO ₂ content in fuel of 0.0019 lb SO ₂ /MMBtu
		0.9 lb SO ₂ /MW-hour	Projected emissions of 0.019 lb SO ₂ /MW-hour from the proposed Renewal Project Gas Turbine alone

Regulation 11, Rule 10: Hexavalent Chromium Emissions from Cooling Towers

The Refinery has not used chromium based water treatment since 1989, and is expected to continue to comply with the requirements of District Regulation 11, Rule 10.

Regulation 11, Rule 12: NESHAP from Benzene Waste Operations

The Refinery is currently subject to the general provision portions of 40 CFR Part 60 Subpart FF. The Refinery will continue to be subject to 40 CFR Part 60 Subpart FF after implementation of the Renewal Project and is expected to comply with this regulation.

Regulation 12, Rule 11, Flare Monitoring at Petroleum Refineries and Regulation 12, Rule 12, Flares at Petroleum Refineries

The new Hydrogen Plant will have a Hydrogen Plant Flare S-6021 that will only flare hydrogen, pressure swing absorption gas, and refinery fuel/process gas during startups and shutdowns, or if there is an emergency upset. District Regulation 12, Rules 11 and 12, applies to petroleum refineries, which are defined for the purposes of the rule as: "A facility that processes petroleum, as defined in the North American Industrial Classification Standard No. 32411 and including any associated sulfur recovery plant."

Since the Hydrogen Plant may handle refinery process gas, the Hydrogen Plant Flare will be subject to BAAQMD Regulation 12, Rules 11 and 12. The flare will be used exclusively to burn hydrogen, pressure swing absorption gas, and refinery process/fuel gas that is generated or

received by the plant, and will fire natural gas exclusively in the pilots for the flare. The process streams and the natural gas pilot both have inherently low sulfur content. The Hydrogen Plant will use refinery process/fuel gas as a feed stream. The Hydrogen Plant Flare will also be subject to the monitoring requirements of District Regulation 12, Rules 11 and 12. Regulation 12-12 requires refineries such as Chevron to reduce emissions from flares by minimizing the frequency and magnitude of flaring. Both Chevron and Praxair have submitted Flare Minimization Plan (FMP) updates for the Renewal Project per Regulation 12-12.

STATE REQUIREMENTS

The Refinery is subject to the Air Toxic “Hot Spots” (ATHS) Program contained in the California Health and Safety Code Section 44300 et seq. Chevron has previously prepared a facility-wide Health Risk Assessment under the ATHS program, and is required to update its toxics emissions inventory on an annual basis. The Renewal Project is not expected to change the facility’s ATHS program status (i.e., “Level 0”).

OTHER FEDERAL REQUIREMENTS

40 CFR Part 60 - Subpart A, NSPS General Provisions

The Refinery is currently subject to the general provision portions of 40 CFR Part 60 Subpart A. According to documents included in the permit application submitted to the District, the Refinery will continue to be subject to 40 CFR Part 60 Subpart A after implementation of the Renewal Project and is expected to continue to comply with this regulation.

40 CFR Part 60 - Subpart J, NSPS for Petroleum Refineries

The following sources are subject to Subpart J: S-4227 Sulfur Plant Claus Unit, S-4228 Sulfur Plant Claus Unit, S-4229 Sulfur Plant Claus Unit, S-4471 Train 1 Hydrogen Plant Furnace, S-4472 Train 2 Hydrogen Plant Furnace, S-4473 Hydrogen Plant Cogeneration Turbine 3, S-4474 Heat Recovery Steam Generation 3, S-4477 CCRR 1 Preheat Furnace, S-4478 CCRR 2 Reheat Furnace, S-4479 CCR 3 Reheat Furnace, S-4480 CCRR 4 Reheat Furnace.

60.104 Standards for Sulfur Oxides.

60.104(a)(1): Fuel gas H₂S limited to 230 mg/dscm (0.10 gr/dscf) except for gas burned as a result of process upset or at flares from relief valve leaks or other emergency malfunctions.

60.104(a)(2)(i): Limit on sulfur dioxide emissions from Claus sulfur recovery plants of 250 ppmv, dry at 0% O₂.

The Refinery’s fuel system and the Claus units are already subject to these respective emission limits and will continue to be subject.

60.105: Monitoring of emissions and operations.

The Refinery's fuel system is already equipped with H₂S CEMs, which will remain in service. Claus units S-4227, S-4228 and S-4229 are already equipped with SO₂ CEMs, which will remain in service.

According to documents included in the permit application submitted to the District, the sulfur content of the pipeline natural gas will be documented using information provided by the gas supplier and will be required to do so by permit condition on a daily basis.

On June 24, 2008, EPA published in the Federal Register final amendments to the current standards of performance for petroleum refineries and separate standards of performance for new, modified, or reconstructed process units at petroleum refineries (New Source Performance Standards, Subparts J and Ja, published at 73 Federal Register 35838). Subpart J provides for an effective date of June 24, 2008 for flare requirements, an effective date of May 14, 2007 for FCC Regenerators, fuel gas combustion devices, and Sulfur Recovery Units. Subpart Ja has an effective date of June 24, 2008 for flare requirements, and an effective date of May 14, 2007 for FCCUs, FCUs/cokers, fuel gas combustion devices, process heaters, and Sulfur Recovery Units. The EPA stayed the effective date of the rule (Subpart Ja) for the newly promulgated standards of performance for new, modified, or reconstructed process units at petroleum refineries. The effective date for the final rule promulgating amendments to the current standards (Subpart J) of performance for petroleum refineries is not changing and remains June 24, 2008. When the EPA stay ends, the District will re-evaluate applicability based on the outcome of the changes.

40 CFR Part 60 - Subpart Kb, NSPS for Volatile Organic Liquid Storage Vessels

The Refinery is currently subject to the general provision portions of 40 CFR Part 60 Subpart Kb. The Refinery will continue to be subject to 40 CFR Part 60 Subpart Kb after implementation of the Renewal Project and according to documents included in the permit application submitted to the District, is expected to continue to comply with this regulation.

40 CFR Part 60 - Subpart GG, NSPS for Stationary Gas Turbines

See Discussion for District Regulation 10.

Equipment Leaks:

40 CFR Part 60 - Subpart VV, NSPS for Leaks of VOC in the Synthetic Organic Chemicals Manufacturing Industry for which Construction, Reconstruction, or Modification Commenced After January 5, 1981, and on or Before November 7, 2006

40 CFR Part 60 - Subpart GGG, NSPS for Equipment Leaks of VOC in Petroleum Refineries

40 CFR Part 61 - Subpart J, NESHAP for Equipment Leaks (Fugitive Emission Sources) of Benzene

40 CFR Part 63 - Subpart H, NESHAP MACT for Equipment Leaks

The Refinery is currently subject to the equipment leak provisions of 40 CFR Parts 60, 61 and 63. The Refinery will continue to be subject to these requirements after implementation of the Renewal Project and according to documents included in the permit application, is expected to continue to comply with this regulation.

40 CFR Part 60 - Subpart QQQ, NSPS for Petroleum Refinery Wastewater Systems

The Refinery is currently subject to the general provision portions of 40 CFR Part 60 Subpart QQQ. The Refinery will continue to be subject to 40 CFR Part 60 Subpart QQQ after implementation of the Renewal Project and according to documents included in the permit application, is expected to continue to comply with this regulation.

40 CFR 60 - Subpart KKKK, NSPS for Stationary Combustion Turbines

See discussion above on District Regulation 10 compliance. The refinery is in compliance with more stringent District requirements.

40 CFR Part 61 - Subpart FF, NESHAP for Hazardous Air Pollutants from Benzene Waste Operations

See District Regulation 11-11 (NESHAP requirements for this source category are incorporated by reference).

40 CFR Part 61 - Subpart V, NESHAP for Equipment Leaks (Fugitive Emission Sources)

See Discussion for District Regulation 11, Rule 7 (Standard incorporated by reference)

40 CFR Part 63 - Subpart Q, NESHAP MACT for Industrial Process Cooling Towers

According to documents included in the permit application submitted to the District, the Refinery has not used chromium based water treatment since 1989 and is expected to continue to comply with the requirements of 40 CFR Part 63 Subpart Q.

40 CFR Part 63, - Subpart CC, NESHAP MACT for Petroleum Refineries

The Refinery is an existing affected source as defined in 63.640(c) and is subject to Subpart CC. Pursuant to 63.648(a), for components containing or contacting hazardous air pollutants (HAPs). According to documents included in the permit application submitted to the District, the Refinery shall continue to comply with the provisions of 40 CFR part 60 subpart VV.

40 CFR Part 63 - Subpart UUU, NESHAP MACT for Hazardous Pollutants for Petroleum Refineries: Catalytic Cracking Units, Catalytic Reforming Units, and Sulfur Recovery Units

S-4227, S-4228 and S-4229, Sulfur Recovery Unit Trains #1, #2 and #3 are subject to 40 CFR

63, Subpart UUU. This standard is essentially equivalent to the SO₂ standard in 40 CFR 60, Subpart J. According to documents included in the permit application submitted to the District, these units will comply with the SO₂ standard and with the requirement for continuous SO₂ monitoring. The CCRR will comply with the requirements for catalytic reforming units.

40 CFR 63 - Subpart DDDDD, NESHAP MACT for Industrial, Commercial, and Institutional Boilers and Process Heaters

S-4471 and S-4472 Reformer Furnaces for Hydrogen Plant Trains #1, and #2; and S-4477, S-4478, S-4479 and S-4480 Reformer Furnaces #1, #2, #3 and #4 are subject to 40 CFR 63, Subpart DDDDD, National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters. The Washington DC Circuit Court vacated this standard on June 8, 2007. Where there is no MACT for a new source and the deadline for promulgation of a standard by the EPA is past, local agencies must determine on a case-by-case basis, MACT for the new source, in accordance with 40 CFR 63.52(a). The emission limit for these sources in the vacated standard was 400 ppm CO. There were no other limits for gaseous-fueled boilers. A CO CEM was not required for units under 100 MMBtu/hour.

The reason that the court gave for vacating the MACT standard was that the EPA had inappropriately classified solid waste incineration units that were subject to Section 129 of the Clean Air Act as solid fuel units that were subject to the MACT standard. This classification greatly increased the number of units subject to the MACT standard and therefore skewed the determination of the MACT floor. The court stated that the "universe of units ... will be far smaller and more homogenous [sic]" after the solid waste units were taken out of the group of units affected. The court expects that the rule will change substantially when the EPA considers the smaller pool of units.

One possible outcome is that the standards may become more stringent because the HAP emissions from the solid waste incineration units are expected to be higher. The MACT "floor" is based on the performance of the top 12 percent of the units in a category.

The EPA had determined that CO was an appropriate surrogate for organic HAPs. The argument was that high CO was indicative of poor combustion and therefore, poor destruction of organic HAPs. This is a reasonable assumption.

The District does not have the resources to survey all industrial, commercial, and institutional boilers and process heaters in the United States and determine the MACT "floor." However, the District notes that the CO BACT limit in the District's BACT workbook for boilers over 50 MMBtu/hr has been 50 ppmv since 2005. For refinery process heaters over 50 MMBtu/hr, the BACT limit has been 50 ppmv since 1994. The South Coast AQMD has had BACT limits for CO of 50 ppm for boilers since 2000.

On page 1680, column 3, second paragraph, of the MACT proposal published on January 13, 2003, the EPA states:

"The approach that we use to calculate the MACT floors for new sources is somewhat

different from the approach that we use to calculate the MACT floors for existing sources. While the MACT floors for existing units are intended to reflect the average performance achieved by a representative group of sources, the MACT floors for new units are meant to reflect the emission control that is achieved in practice by the best-controlled source. Thus, for existing units, we are concerned about estimating the central tendency of a set of multiple units, while for new units, we are concerned about estimating the level of control that is representative of that achieved by a single best controlled source."

Since the District agrees with the EPA that low CO levels indicate low levels of organic HAPs, then lower CO levels are better than higher CO levels. Considering that the "best-controlled sources" have CO levels that are 50 ppm or lower, and the Project will be limited to a CO level of 10 ppm CO at 3% O₂, this level of control will be considered to be the presumptive MACT level for these sources until the EPA re-proposes and re-promulgates MACT.

All these sources will be equipped with NO_x and CO CEMs.

40 CFR 64, Compliance Assurance Monitoring

According to documents included in the permit application submitted to the District, all subject sources shall comply with the requirements of 40 CFR Part 64.

40 CFR 70, Title V, Operating Permits

The Refinery is subject to the Title V program because it is a major facility as defined by BAAQMD Regulation 2-6-206. The date of initial issuance of the Refinery's Title V permit was December 1, 2003. The Title V permit has been revised several times after initial issuance, and an application for the five-year renewal has been submitted.

The changes proposed in this application require a significant revision of the Title V permit because the Renewal Project is subject to the following District regulations:

- 2-6-226.2: The incorporation of a change considered a modification under 40 CFR Parts 60 (NSPS) and 63 (MACT)
- 2-6-226.4: The establishment of or change to a permit term or condition allowing a facility to avoid an applicable requirement
- 2-6-226.5: The establishment of or change to a case-by-case determination of any emission limit or other standard

The required revisions to the Title V permit will be prepared at a later date and are subject to publication and public comment, and EPA review.

40 CFR 72-78, Acid Rain

S-4473 3rd Cogeneration Gas Turbine and S-4474 3rd Cogeneration HRSG with Duct Burners may be subject to the requirements of Title IV of the federal Clean Air Act. The requirements of the Acid Rain Program are outlined in 40 CFR Part 72. The specifications for the type and

operation of continuous emission monitors (CEMs) for pollutants that contribute to the formation of acid rain are given in 40 CFR Part 75. District Regulation 2, Rule 7 incorporates by reference the provisions of 40 CFR Part 72. Pursuant to 40 CFR Part 72.30(b)(2)(ii), should the cogeneration unit become subject to the Acid Rain Program, Chevron must submit an Acid Rain Permit Application to the District at least 24 months prior to the date on which each unit commences operation. Pursuant to 40 CFR Part 72.2, "commence operation" includes the start-up of the unit's combustion chamber.

PUBLIC NOTICE/COMMENTS

Requirements for publication and public comment of preliminary permit decisions are specified in District Regulation 2-2-405. The Renewal Project permit application is not subject to these requirements because: (1) it is not a new major facility, (2) it is not a major modification of an existing major facility as defined in Regulation 2-2-221, (3) it does not require a PSD analysis, and (4) it is not subject to the MACT Requirement as defined in Regulation 2-2-317.

It is clear that this project's net emissions (i.e., emission increases from new, modified sources minus contemporaneous actual emission reductions from sources to be shutdown) do not exceed any of the emissions thresholds that would constitute a major modification under Regulation 2-2-221. These are 40 tons per year of POC, NO_x or SO₂; 100 tons per year of CO; and 15 tons per year of PM₁₀.

The term "PSD Analysis" is not defined in Regulation 2-2, however, "PSD Air Quality Analysis" is defined in Regulation 2-2-414. The District has consistently interpreted that the terms "PSD Analysis" and "PSD Air Quality Analysis" are interchangeable and synonymous. In other words, a PSD Analysis or PSD Air Quality Analysis only occurs when a facility hits a PSD trigger, and does not apply when PSD netting demonstrates that no trigger has been hit.

The term "MACT Requirement" is defined in Regulation 2-2-317. This Section refers to Regulation 2-2-114, which provides a series of exemptions. The MACT Requirement would apply if any of the sources in the Project were subject to case-by-case MACT determination under Clean Air Act Section 112(g). This is not the case.

Although it is not required by regulation, due to the public interest in the Renewal Project, the Executive Officer/Air Pollution Control Officer decided that the District, in collaboration with the City of Richmond Planning Department, should hold a community meeting in Richmond to discuss air quality issues associated with the Renewal Project and the District's permit process. This well-attended community meeting was held on February 13, 2008 in Richmond. District staff also attended numerous public meetings held regarding the City of Richmond's EIR certification and conditional use permit issuance.

Some of the public comments expressed at the meetings concerned air quality issues. In particular, because the Renewal Project would allow Chevron to run a crude oil blend with a higher sulfur content than current blends, many of these comments requested a "Comprehensive Crude Cap" on the Refinery. Under this approach, a Comprehensive Crude Cap would limit the sulfur content of incoming crude and gas oils to that of historical baseline levels. Limits would

also be similarly established for other constituents in these incoming materials to be refined at the facility.

On April 30, 2008, the District met with representatives of Communities for a Better Environment (CBE) to discuss the comprehensive crude cap issue. At the meeting, CBE representatives presented a graph, which asserted that crude sulfur content correlates to flare SO₂ emissions. The District has reviewed the graph, as well as other data provided by CBE, and is not convinced that this correlation is valid. Furthermore, the District is confident that District Regulation 12-12 will continue to identify and implement reductions in flaring events.

The City of Richmond hired Dr. Ranajit Sahu, an environmental engineering consultant, to respond to the “Comprehensive Crude Cap” comments from the public. Appendix D contains Dr. Sahu’s responses to comments from Communities for a Better Environment (CBE). At the June 5th Planning Commission meeting, Dr. Sahu indicated that there is not a clear nexus from crude sulfur content to SO₂ flaring emissions. The District is satisfied that limiting the sulfur content in the refinery fuel gas, and subjecting the modified SRUs to BACT, adequately address the increased sulfur loading from the Renewal Project. Flare SO₂ emissions will be addressed on an ongoing basis through District Regulations 12-11 and 12-12.

District staff was present at the Planning Commission meeting on June 5th, where Dr. Sahu presented his responses to the comments. Dr. Sahu identified the Solvent Deasphalting (SDA) Plant, S-4251, as a bottleneck for the handling of heavier, higher sulfur, crude slates after a thorough review of Chevron’s refining process. Dr. Sahu recommended that a reduced throughput limit at the SDA Plant would limit the Refinery’s ability to handle heavier crudes. The District has determined that the City of Richmond’s Conditional Use Permit conditions and review adequately addressed the comments on this issue. Pursuant to the Use Permit’s Condition C12, Chevron has submitted a permit application for a revision to its Major Facility Review (Title V) Permit to decrease the daily and annual throughput limits of the SDA Plant in the Refinery’s Title V permit. The District received the minor revision permit application on August 15, 2008 (District Permit Application No. 18740).

District staff has worked closely with City of Richmond Planning Division, the preparers of the Environmental Impact Report (EIR) for the Renewal Project, and Dr. Sahu regarding the Renewal Project. District staff has considered public input expressed in recommending a final action on this application. The District is satisfied that the SDA Plant condition in the City of Richmond’s Conditional Use Permit, the permit application to establish a new lowered SDA Plant throughput limit, District-imposed permit conditions on the RFG and SRUs, and numerous other permit conditions that monitor and limit the emissions or various regulated air pollutants adequately address this issue.

CEQA

CEQA requires public agencies to evaluate the potential environmental impacts of certain types of “projects” before approving the project. (Public Resources Code §21080). In accordance with District Regulation 2-1-310.3, the District may not issue an Authority to Construct for this project until final action has been taken by the CEQA Lead Agency.

The City of Richmond is the CEQA Lead Agency for the Renewal Project. A draft EIR for the Project was issued by the City's Planning Department in May 2007. The District, as a CEQA Responsible Agency, provided comments on the draft EIR. These comments, as well as others, were addressed in a Final EIR. An electronic copy of the Final EIR is available for review at the following link: <http://www.ci.richmond.ca.us/index.asp?NID=832>.

The Richmond Planning Commission certified that the Final EIR was prepared in compliance with the California Environmental Quality Act. The Richmond Planning Commission considered the EIR at noticed public hearings on April 10, 2008, and June 5, 2008. The Final EIR was certified on July 17, 2008. The City of Richmond filed a Notice of Determination on August 5, 2008.

Final action by the District will be taken only after careful review and consideration of the information in the Project's certified EIR. As a Responsible Agency, the District has prepared findings for the purposes of CEQA. The findings are attached in Appendix F.

RECOMMENDATIONS

The District recommends that the Chevron Richmond Refinery be issued a Conditional Authority to Construct for the following:

HYDROGEN PLANT REPLACEMENT

New Equipment

S-4449 Hydrogen Plant Train #1, 140 MM SCFD Hydrogen Produced maximum capacity

S-4450 Hydrogen Plant Train #2, 140 MM SCFD Hydrogen Produced maximum capacity

S-4451 Hydrogen Recovery Unit, 50 MM SCFD Hydrogen Recovered maximum capacity

S-4471 Hydrogen Plant Train #1 Reformer Furnace, 950 MMBtu/hr maximum firing rate higher heating value (HHV), equipped with Low-NO_x Burners abated by **A-0302** Hydrogen Plant Train #1 Selective Catalytic Reduction (SCR) [Vented to **P-0302** Hydrogen Plant Train #1 Furnace Exhaust]

S-4472 Hydrogen Plant Train #2 Reformer Furnace, 950 MMBtu/hr maximum firing rate HHV, equipped with Low-NO_x Burners abated by **A-0303** Hydrogen Plant Train #2 SCR [Vented to **P-0303** Hydrogen Plant Train #2 Furnace Exhaust]

S-4465 Hydrogen Plant Cooling Tower, 36,000 gal/min maximum capacity

S-6021/A-6021 Hydrogen Plant Flare, 1.6 MMBtu/hr Pilot maximum capacity HHV, [Vented to **P-0305** Hydrogen Plant Flare Exhaust]

Shutdown of Existing Equipment

S-4250 Hydrogen Plant, Trains A and B, (Total Combined Capacity 150 MMSCFD) Train A abated by: **A-261** Packed Bed Scrubber De-aerator Vent (Methanol), Exhaust to P-261 and Train B abated by: **A-262** Packed Bed Scrubber De-aerator Vent (Methanol), Exhaust to P-262

S-4170 Hydrogen Plant Train A Reformer Furnace F-305 (820 MMBtu/hr) Exhaust to P-123, P-124, P-125, P-126 abated by **A-260** Hydrogen Plant Train A SCR System

S-4171 Hydrogen Plant Train B Reformer Furnace F-355 (820 MMBtu/hr)
Exhaust to P-127, P-128, P-129, P-130

S-4348 Hydrogen Recovery Unit (1.1 ton/hour max), Exhaust to S-6039

S-4156 Feed Furnace F-320 (41 MMBtu/hr), Exhaust to P-114

S-4157 Feed Furnace F-330 (41 MMBtu/hr, Multi-fuel), Exhaust to P-115

S-4158 Feed Furnace F-340 (48 MMBtu/hr), Exhaust to P-116

REFORMER REPLACEMENT

New Equipment

S-4452 Continuous Catalyst Regeneration Reformer, 71,300 BPD maximum capacity
[Vented to **P-0308** CCRR Regeneration Vent]

S-4477 Reformer Furnace #1, 201 MMBtu/hr maximum firing rate HHV, equipped with
Low-NO_x Burners abated by **A-0309** SCR

S-4478 Reformer Furnace #2, 402 MMBtu/hr maximum firing rate HHV equipped with
Low-NO_x Burners abated by **A-0309** SCR

S-4479 Reformer Furnace #3, 201 MMBtu/hr maximum firing rate HHV equipped with
Low-NO_x Burners abated by **A-0309** SCR

S-4480 Reformer Furnace #4, 201 MMBtu/hr maximum firing rate HHV equipped with
Low-NO_x Burners abated by **A-0309** SCR

A-0309 SCR for CCRR Furnaces #1 - #4 (S-4477, S-4478, S-4479, S-4480) [Vented to
P-0309 Reformer Furnaces #1 - #4 (S-4477, S-4478, S-4479, S-4480)]

Shutdown of Existing Equipment

S-4283 No. 4 Catalytic Reformer (28 MBPD)

S-4038 No. 4 Rheniformer Furnace, F-3550 (187 MMBtu/hr), Exhaust P-40, P-41

S-4039 No. 4 Rheniformer Furnace, F-3560 (170 MMBtu/hr), Exhaust P-40, P-41

S-4040 No. 4 Rheniformer Furnace, F-3570 (152 MMBtu/hr), Exhaust P-40, P-41

S-4041 No. 4 Rheniformer Furnace, F-3580 (77 MMBtu/hr), Exhaust P-40, P-41

S-4237 No. 5 Catalytic Reformer (23 MBPD)

S-4042 No. 5 Rheniformer Furnace, F550 (198 MMBtu/hr), Exhaust P-42, P-43
Unit Equipped with 36-Ultra Low NO_x Burners

S-4043 No. 5 Rheniformer Furnace, F-560 (133 MMBtu/hr), Exhaust P-42, P-43

S-4044 No. 5 Rheniformer Furnace, F-570 (78 MMBtu/hr), Exhaust P-42, P-43

S-4045 No. 5 Rheniformer Furnace, F-580 (51 MMBtu/hr), Exhaust P-42, P-43

POWER PLANT REPLACEMENT

New Equipment

S-4473 3rd Cogeneration Gas Turbine, 550 MMBtu/hr maximum firing rate HHV. Combined Gas Turbine and HRSG equipped with Duct Burners 860 MMBtu/hr firing rate (calendar day). Combined Gas Turbine and HRSG equipped with Duct Burners 840 MMBtu/hr maximum firing rate (annual average)

S-4474 3rd Cogeneration Heat Recovery Steam Generator (HRSG) equipped with Duct Burners, equipped with Low-NO_x Burners 350 MMBtu/hr Duct Burner maximum firing rate HHV. Combined Gas Turbine and HRSG equipped with Duct Burners 860 MMBtu/hr firing rate (calendar day). Combined Gas Turbine and HRSG with Duct Burners 840 MMBtu/hr maximum firing rate (annual average)

A-74 SCR abating both 3rd Cogeneration Gas Turbine and Heat Recovery Steam Generator

A-75 Oxidation Catalyst abating both 3rd Cogeneration Gas Turbine and Heat Recovery Steam Generator [Vented to **P-0306** 3rd Cogeneration Gas Turbine/Heat Recovery Steam Generator]

Shutdown of Existing Equipment

S-4129 Boiler No. 1 (233 MMBtu/hr)

S-4131 Boiler No. 3 (236 MMBtu/hr)

S-4132 Boiler No. 4 (235 MMBtu/hr)

S-4133 Boiler No. 5 (237 MMBtu/hr)

S-4135 Boiler No. 7 (272 MMBtu/hr)

HYDROGEN PURITY IMPROVEMENTS

New Equipment

S-4454 #6 H₂S Plant, Recycle Amine Regenerator, 11 MMSCFD maximum capacity

S-4490 Sulfur Loading Rack, 157 LT/hr maximum capacity abated by **A-0310** Sulfur Loading Rack Caustic Scrubber [Vented to **P-0310** Sulfur Loading Rack Caustic Scrubber Exhaust]

A-4450 Acid Gas Scrubber (C-2440), 11 MMSCFD Acid Gas for abatement of: #3 H₂S Plant (S-4433), #4 H₂S Plant (S-4434), #5 H₂S Plant (S-4435), Recycle Amine Regenerator (S-4454), and the #8 NH₃-H₂S Plant (S-4429) and #18 NH₃-H₂S Plant (S-4345)

S-4436 F-2170 Stack Gas Heater No. 1 SRU, 31.9 MMBtu/hr maximum firing rate HHV [vented to **P-0151** SRU Train #1 Exhaust]

S-4437 F-2270 Stack Gas Heater No. 2 SRU, 31.9 MMBtu/hr maximum firing rate HHV [Vented to **P-0152** SRU Train #2 Exhaust]

S-4438 F-2370 Stack Gas Heater No. 3 SRU, 56.1 MMBtu/hr maximum firing rate HHV [Vented to **P-0153** SRU Train #3 Exhaust]

S-4456 Fresh Amine Storage Tank, 70,000 gal maximum capacity

S-3227 Lean Amine Storage Tank, 130,000 gallon maximum capacity

S-3228 Caustic Storage Tank, 200,000 gallon maximum capacity

S-3229 Spent Caustic Storage Tank, 400,000 gallon maximum capacity

Modification of Existing Equipment

S-4253 TKC/FCC Feed Hydrotreater, 96,000 BPD maximum capacity

S-4435 No. 5 H₂S Plant, 9.6 MMSCFD maximum capacity

S-4227 Sulfur Recovery Unit Train #1, 345 LTD maximum capacity abated by both **A-0020** SRU#1 Tail Gas Unit Thermal Oxidizer 30.8 MMBtu/hr HHV maximum firing rate and **A-120** Wet Electrostatic Precipitator (ESP)

S-4228 Sulfur Recovery Unit Train #2, 345 LTD maximum capacity abated by **A-0021** SRU#2 Tail Gas Unit Thermal Oxidizer 30.8 MMBtu/hr HHV maximum firing rate and **A-121** Wet Electrostatic Precipitator (ESP)

S-4229 Sulfur Recovery Unit Train #3, 570 LTD maximum capacity abated by **A-0022** SRU#3 Tail Gas Unit Thermal Oxidizer 45.0 MMBtu/hr HHV maximum firing rate and

A-122 Wet Electrostatic Precipitator (ESP)

The District recommends that the Chevron Richmond Refinery be issued a Conditional Permit to Operate for the following:

A-4451 Acid Gas Scrubber (C-840), 12.5 MMSCFD Acid Gas for abatement of: #3 H₂S Plant (S-4433), #4 H₂S Plant (S-4434), #5 H₂S Plant (S-4435), Recycle Amine Regenerator (S-4454), and the #8 NH₃-H₂S Plant (S-4429) and #18 NH₃-H₂S Plant (S-4345).

OTHER ALTERED EQUIPMENT

Retrofitting of Existing Furnaces with Low NO_x Burners (Reg. 9-10 Compliance)

S-4161 F-510 TKN Furnace, 61 MMBtu/hr maximum firing rate HHV, equipped with Low-NO_x Burners

S-4162 F-520 TKN Furnace, 61 MMBtu/hr maximum firing rate HHV equipped with Low-NO_x Burners

S-4163 F-530 TKN Furnace, 61 MMBtu/hr maximum firing rate HHV equipped with Low-NO_x Burners [Vented to **P-0311** TKN Furnace Exhaust]

S-4188 F-651 Polymer Furnace, 27 MMBtu/hr maximum firing rate HHV equipped with Low-NO_x Burners [Vented to **P-0312** Polymer Furnace Exhaust]

S-4189 F-661 Polymer Furnace, 15 MMBtu/hr maximum firing rate HHV equipped with Low-NO_x Burners [Vented to **P-0313** Polymer Furnace Exhaust]

Chevron Renewal Project
SO2 Shutdown Sources and New Sources
BAAQMD September 2008

RENEWAL Permit Potential SOx

Non Drum SO2 Increases (Must Be Offset)

Sulfur Recovery Unit Increase	29.06
H2 Plant Condition	5.25
CCR Vent	1.00
Total Non Drum SO2	35.31

New Drum SO2 (Accounted for in Bubble)

New RFG at CCRR Furnaces	11.65
New RFG at Cogen Duct Burner	7.46
LPG at Cogen	3.33
Natural Gas at Cogen	0.74
Total New Drum SO2 to be included in Drum SO2 Limit of 53.15 tons/year	23.17

Total Renewal Permit Potential SOx (ton/year)	58.48
--	--------------

Potential RENEWAL Baseline/Shutdown SOx tons/year	47.01
Potential RFG Sources Shutdown	46.95
Potential Other Shutdown (Rheniformer)	0.06

Potential Shutdown Reductions Used to Offset New Non Drum SO2

Potential RENEWAL Baseline/Shutdown SOx tons/year	47.01
Non Drum Increases SO2 Increases	35.31
Potential Leftover Emission Reductions	11.70

New Permit Limit at Refinery Fuel Gas Drums

Potential Baseline Refinery Fuel Gas System All Sources Refinery Wide	101.64
Potential Renewal Shutdown RFG Sources	46.95
Potential Baseline Refinery Fuel Gas System Non Renewal Sources	54.69
Permit Limit at Refinery Fuel Gas Drums	53.15
Potential Reduction at Drums = Potential Baseline Drums non Shutdown - New Drum Limit	1.54

Potential Reduction of SO2 = (Total Shutdown - Non Drum SO2 Increases) + Difference at Drums	13.24
--	-------

Notes:

New Drum SO2 is a potential to emit value and will be included as part of the new 53.15 ton/year permit limit.

Fuel Drum Permit Limit of 53.15 tons/year SO2 is the sum of all three fuel gas drums + Cogen Natural Gas + Cogen

The Refinery will have to lower the sulfur content in the RFG system and/or burn less RFG to manage emissions w

All potential SO2 emissions reductions will need to be evaluated in a future District Banking Application.

Potential Baseline for Refinery Fuel Gas System
SO2 lb/MMBtu for Baseline = (101.64 tons/year x 2000 lb/ton)/(106.87 MMscf/day x 979.26 Btu/scf x 365 day/year) = 0.00532 lb/MMBtu

Permit Potential Using Permit Limit for Total Sulfur for Fuel Gas System
SO2 lb/MMBtu for Future based on future SO2 concentration = 30.85 E-06 x 1/379 dscf/lb-mol x 32 lb/lb-mol x 64 lb/lb-mol/32 lb/lb-mol x 1/979.26 x 1 E06 Btu/MMBtu = 0.00532 lb/MMBtu

Potential Baseline Shutdown Sources	Baseline MMBtu/yr	SO2 ton/yr
S-4170 H2 Plant Furnace	4932983	13.12
S-4171 H2 Plant Furnace	4414649	11.74
S-4156, S-4157, S-4158 H2 Plant Feed Furnaces	291564	0.78

Total Renewal Permit Potential, (tons/year)	116.14
---	--------

RENEWAL Potential Baseline with SRU SO2 tons/year	104.65
RENEWAL Permit Potential with SRU SO2 tons/year	116.14
Difference	11.48

Notes:
Chevron Plans to reduce SO2 emissions from the Refinery by limiting the sulfur content in the Refinery Fuel Gas System.
This will reduce the SO2 emissions from all Refinery Fuel Gas fired sources at the Refinery.
All potential SO2 emissions reductions will need to be evaluated in a future District Banking Application.

APPENDIX B
TAC EMISSIONS CALCULATIONS

1) Simplified Speciation for Permit Potential Case. PERF gas and liquid speciations by plant are used to develop combined conservative speciation by plant. Combined Speciation then applied to final permit potential fugitive estimate. Fugitive in this Spreadsheet were calculated by BAAQMD using PERF speciation data. Where Rev 8 had estimates for compounds not included in the speciation data. The Rev 8 estimates were retained for these compounds. The BAAQMD calculation for xylene fugitives at the H2 plant was lower than Rev 8. The Rev 8 value was retained. As shown in PERF Speciation Permit Potential Fugitive Estimate 083107

2) Cogen Cooling Tower S-4325 Removed for Estimate

3) Hourly H2S Estimate for S-4396 Sulfur Loading Rack revised from 0.00661 lb/hr to 0.0245 lb/hr

4) Source Numbers for Cogen Corrected to S-4473 Turbine, S-4474 HRSG Duct Burner

5) Removed Emission Reduction of Methanol at Bio Reactor S-4393 (Per Rob Johnston conversation 8/29/07)

6) Corrected DEA at TKC and SRU (#6 H2S) Annual and Maximum Hourly, TKC 455 lb/year, SRU 1150 lb/year

7) Chevron's hourly H2S emissions rate from S-4396 from 6.61E-3 #/hr to 3.67E-2 #/hr.

8) Revised SRU H2SO4 emission rates to agree with Chamberlin Email of 9/6/07. Max Hourly 1 and 2 at 345 LT/day abated 90%, 3 at 225 LT/day unabated H2SO4 estimates are calculated in Renewal Project SAM Calculation Spreadsheet dated 091407.

9) The H2SO4 estimate for other RFG fired sources was adjusted from 1413.6 lb/year to 1,680.1 lb/year.

Total RFG = Shutdown Renewal SO2 + Existing SO2 = 101.64 = 46.78 Shutdown + 54.86 Existing

H2SO4 Non Renewal RFG sources = 54.86 tons/year x 2000 x 98/64 x 0.01 = 1680.1 lb/year

H2SO4 Non Renewal RFG sources = 1680.1 lb/year/8760 hr/year = 0.19 lb/hr

10) The annual H2SO4 originally in this file were not adjusted for the 14 days of unabated operation.

	CEQA Run	Corrected	Difference
	lb/year	lb/year	lb/year
SRU 1	-11640	-10860	780
SRU 2	-10240	-9740	500
SRU 3	-15420	-14340	1080

The corrected lb/year values have been entered into this spreadsheet.
The corrected values were calculated in the Chevron Renewal SAM Calculation spreadsheet dated 9/14/07.

Changes on 10/12/07

Cogen Max Hourly Firing Rate was 860 MMBtu/hr now 900 MMBtu/hr

Changes on 2/04/08

- 1) CATEF Emission Factors from RFG Emission Factors spreadsheet
- 2) All Shutdown Sources removed

- 3) All documentation in other documents pulled into R9
- 4) All fugitive emissions based on District PERF spreadsheet, and misc fugitive NH3 sheet

Changes on 2/25/08

- 1) DEA lb/year value removed from H2 Plant Fugitive estimate. No basis.
- 2) H2S and Perc estimates removed from CCR Fugitive estimate. No basis.
- 3) H2 Plant Fugitive NH3 from SCR systems increased from 32.1 lb/year to 42.48 lb/year. Hourly raised to 0.00485 lb/hr.
- 4) Metals added to H2 Plant cooling tower annual estimate.

Changes on 2/26/08

Antimony and Ethylbenzene max hourly added at SRU for completeness. Neither compound has an acute REL.

Changes on 3/3/08

CCR Fugitive lb/hr had a value for H2SO4, This was erroneous and set to zero.

Changes on 3/24/08

Incorporated Final SAM Calc into R9 Final
Revised Dioxin lb/yr and lb/hr based on higher flowrate 44,045 dscfh
Metals at Cooling Tower were based on ppm concentration data. The data was actually ppb and the calculations have been revised.

Changes 3/27/08

SO2 at H2 Plant Flare increased from 0.04 Tons/year to 0.31 Tons/year.
SAM Values corrected to correspond to new SO2 values.

Changes 4/2/08

H2S at SRU Stacks now at 6 ppm

Changes 4/3/08

H2SO4 Annual at Cogen raised from 26,081 lb/year to 30172 lb/year. Due to SO2 from LPG at Cogen 1.67 ton/year.

7/10/2008

H2SO4 at SRUs Now Max Hourly Rates are used to calcuate annual H2SO4 emissions. Permit limit will be corresponding grains/dscf @ 15000 dscfm for 1 and 2 and 30000 for 3.
H2S Now 3 ppm at SRU stack with a flowrate of 15000 for 1 and 2 and 30000 for 3.

CCR Vent Max Hourly Values doubled to account for catalyst burn off issue and a flowrate of 79835 dscf per hour. Annual values use 44045 dscf per hour. Annual values were not doubled.
Hydrogen Plant Cooling Tower Max Hourly Values now correspond to 36,000 gpm which is the value used for the annual estimate.

August-08

H2S at SRU Stacks now 4 ppm

Xylene	3.22E+02			-3

Note:

1: Scale up from North American Refiner, purging operation dependent

2: Scale up from Canadian refiner and General emission data. Feed contaminant level dependent

3: Scale up from European refiner.

4: Calculate from mass balance and US refiner data analysis

5: Calculate from RMACTII parameter limit and regenerated catalyst chloride loading of 1 wt% for permit only. The concentration is higher than normal operation.

6: Scale up from Canadian and European refiners.

CCR Calculation Continued. Attachment 3 contains UOP's process description and emissions estimate for the Chlorsorb™ control system. As presented in the Project Specification page, UOP estimates the following outlet concentrations of chlorine, hydrochloric acid, and dioxins/furans:

Component	Estimated Concentration
Cl ₂	<10 ppmv
HCl	<150 ppmv
PCDD/PCDF	20 ng TEQ/Nm ³

CCR VENT DIOXIN/FURAN ESTIMATE Chevron has selected a different manufacturer to provide residual dioxin control. In place of Gore, CRI Catalyst will provide the dioxin destruction system. This will consist of a stainless steel catalyst module containing a platinum-based catalyst. The dioxin destruction system is a passive control device and does not require any chemical reagent injection to function.

CRI has stated that they will guarantee in writing 90% removal of dioxin. Chevron will submit the guarantee when received. This is the control efficiency currently assumed in the HRSA. Since the HRSA was done, there have been two other changes. First, the control device inlet concentration has increased from 16.36 to 20 ng TEQ/Nm³. Second, the CCR catalyst circulation rate has decreased from 4,500 to 3,000 lb/hr. This reduces vent gas flow rate and mass emissions of dioxin at a given concentration. The data are summarized in the following two tables. As shown the net result is an estimated reduction in dioxin emissions of about 16%. Therefore, the current HRSA is conservative with regard to dioxin emissions.

The corresponding current values are:

Parameter	Value
Inlet concentration, ng TEQ/Nm ³	20
Catalyst circulation rate, lb/hr	3,000
Vent gas flow rate, SCF/hr	79,835 Worst Case Flow
Dioxin to control device, lb/hr	9.97E-08
Control device efficiency, %	90%
Dioxin emissions, lb/hr	9.97E-09

Parameter	Value
Inlet concentration, ng TEQ/Nm ³	20
Catalyst circulation rate, lb/hr	3,000
Vent gas flow rate, SCF/hr	44,045
Dioxin to control device, lb/hr	4.82E-04
Control device efficiency, %	90%
Dioxin emissions, lb/hr	4.82E-05

ToxicsNew R7.xls

CCR Perchloroethylene

Perc MW	165.8	
Perc concentration	0.5 ppmv	For compliance assurance, assume Perc at half of source test detection limit (1 ppm)
Perc Mole rate	5.81E-05 lbmol/hr	= concentration /10e6 X Vt(lb-mole.hr) --see below
Perc Mole rate	5.09E-01 lbmol/yr	
Per Mass rate	8.44E+01 lb/yr	= Mole rate X MW

CCR Regeneration Vent Gas Calculation

Vent Gas (Vt) = Total Combustion Gas (At)+ Nitrogen Makeup to Regeneration Loop (Mt) -- note: Vent Gas MW ~ 30 lb/lbmol

Nitrogen Makeup is a function of Reactor 4 Operating Pressure (75 psig current estimate) + Regeneration Tower Pressure (35 psig)
Based on similar design, nitrogen makeup ~ 80 MSCFD

Combustion Air Usage

To compute the catalyst circulation rate by air usage, use the following formula:

$$\text{CCR (lb/hr)} = (0.0288) \times \left(\frac{100}{X} - 1 \right) \times A_T \times (0.21 - Y)$$

where:

X	=	5 wt%	spent catalyst coke content, wt-% (design 5 wt%)
CCR	=	4500 lb/hr	catalyst circulation rate,(lb/hr - current estimate at 3000 lb/hr)
Y	=	0.008 mol frac	Burn Zone inlet oxygen concentration, mole fraction (design 0.8 mol%, 0.008 mol Fraction)
AT	=	40711.31 SCFH	total combustion air, (SCFH) -- rearrange Eq. 1 to find total combustion air
At	=	107.4177 lbmol/hr	
Mt	=	3333.333 SCFH	Nitrogen make-up to regeneration loop (80,000 SCFD)
Mt	=	8.795075 lbmol/hr	
Vt	=	44044.64 SCFH	
Vt	=	116.2128 lbmol/hr	
Vt	=	1018024 lb-mol/yr	
Vt	=	3.14E+07 lb/yr	MW 30.85

APPENDIX C
HEALTH RISK SCREENING ANALYSIS

INTEROFFICE MEMORANDUM

July 24, 2008

TO: Barry Young/Greg Solomon
FROM: Jane H. Lundquist *JHL*

Via: Scott B. Lutz *SBL*
Daphne Y. Chong *ayc*

SUBJECT: Revised Health Risk Assessment for Chevron Products Company, Richmond,
Plant #10, Application #12842, Energy Plant and Hydrogen Plant Renewal Project

We have completed a revised health risk assessment for the above referenced permit application based on the latest emission estimates provided in the "TAC R10 BAAQMD Final" spreadsheet dated 7/17/2008, the stack parameter changes provided by the applicant in the "Revised Ch Renewal Stack Parameters 7-8-08" spreadsheet (with SRU stack exit velocities adjusted to correspond to the flowrates used in the TAC emission calculations) and the latest health values adopted by OEHHA. The analysis estimates the incremental health risk resulting from toxic air contaminant (TAC) emissions from the Energy Plant and Hydrogen Plant Renewal Project at this facility. Emissions of 39 different TACs from 11 new sources and 8 modified sources were evaluated. Results from the health risk assessment indicate that, for this project, the maximum incremental cancer risk is estimated at **2 in a million**, the chronic hazard index is **0.3**, and the acute hazard index is **0.9**. In accordance with the District's Regulation 2, Rule 5, these risk levels are considered acceptable. None of the individual source emissions result in a cancer risk that is greater than one in a million nor a chronic hazard that is greater than 0.20. At these risk levels, none of the sources trigger the requirement for TBACT. However, the cogen#3 source, with a chronic hazard index of 0.20, is very close to the TBACT trigger. Table 1 shows the estimated chronic health impacts for the project and for each individual source. Table 2 shows the estimated acute health impacts for the project and for each individual source. In addition, the project, with a 30-day maximum lead concentration of $0.0022 \mu\text{g}/\text{m}^3$, is approvable per the ARB Risk Management Guidelines for New, Modified and Existing Sources of Lead.

EMISSIONS: The health risk value weighted emissions were entered into the model so that the modeled results are in terms of cancer risk, chronic hazard index and acute hazard index. The lead emission input to determine the one-month averaged lead concentration is conservatively based on the maximum one-hour average emission rate of lead. The attached tables show the health values and health value weighted emission inputs used in this analysis. Table 3 shows the health values used for each pollutant, Tables 4, 5 and 6 show the annual average health value weighted emission inputs for combustion point sources, non-combustion point sources, and fugitive sources, respectively. The chronic hazard index weighted emission inputs in Tables 4, 5 and 6 are conservatively calculated summing all hazard quotient weighted emissions regardless of the target organ that is affected by the pollutant. Tables 7 and 8 show the maximum hourly average health value weighted emission inputs for point sources and fugitive sources, respectively. As previously requested, emission rates for the hydrogen plant and CCR furnaces have been scaled up by a factor of two to provide a conservative estimate of risks.

MODELING: The ISCST3 atmospheric dispersion model was used to estimate the chronic and acute health risks. Based on an Auer land use analysis, the facility is located in an area considered rural. Rural dispersion coefficients and five years of on-site meteorological data, 1999 through 2003, were used in the model. Complex terrain impacts were also considered with elevation data extracted from USGS digital elevation maps for Richmond and San Quentin. Impacts due to building down wash were evaluated. Stack, area source, and building parameters used in the analysis are those provided by Chevron. Aerial photos were used to assist in determining location of the emission sources and receptors. For the residential receptors, the initial run was made with a coarser receptor grid. A second residential receptor run was made with a finer receptor grid around the high values found with the initial coarse grid run.

HEALTH RISK: The health risk assessment was performed in accordance with the California Office of Environmental Health Hazard Assessment (OEHHA) guidelines. Multipathway substances for which non-inhalation pathway exposures (soil ingestion, dermal exposure, and mother's milk ingestion) were also evaluated are Arsenic, Cadmium, Lead, Mercury, Nickel, Benzo(a)anthracene, Benz(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Chrysene, Dibenz(a,h)anthracene, Indeno(1,2,3-cd)pyrene and polychlorinated dioxins and furans.

Cancer Risk: Estimates of the maximum incremental residential cancer risk are based on the assumption that the resident is exposed to annual average TAC concentrations over a 70-year lifetime. Estimates of the maximum incremental off-site worker cancer risk are based on the assumption that an off-site worker is exposed eight hours per day, 245 days per year for 40 years out of a 70-year lifetime. The cancer risk results are presented in the following table.

Receptor	Location		Cancer Risk in a million
	UTM_E	UTM_N	
Residential	554275	4197050	1.0
Worker	552540	4199105	1.9

Chronic Hazard Index: Estimates of the maximum incremental residential chronic hazard index are based on the assumption that the resident is exposed to annual average TAC concentrations. Estimates of the maximum incremental off-site worker chronic hazard index are based on the assumption that an off-site worker is exposed eight hours per day, 245 days per year. The results for the chronic hazard index are presented below.

Receptor	Location		Chronic Hazard Index
	UTM_E	UTM_N	
Residential	553750	4197625	0.09
Worker	552540	4199105	0.29

Acute Hazard Index: Estimates of acute hazard index are based on the assumption that the receptor is exposed to maximum one-hour average TAC concentrations. The results for the acute hazard index are presented below.

Receptor	Location		Acute Hazard Index
	UTM_E	UTM_N	
Residential	551171	4201595	0.09
Worker	552085	4200131	0.94

Chronic Non-cancer Health Effects for Lead Exposure: In accordance with the OEHHA guidelines, the chronic non-cancer health effects for lead exposure are not based on a hazard index approach. Instead, air concentrations are compared to defined air lead levels associated with specified percentages of children with blood lead levels (BLLs) $\geq 10 \mu\text{g/dL}$. The location of the 30-day maximum lead ambient air concentration for this project is not in a high exposure area and a simplified approach for assessing non-cancer risk may be used. Per Table 5, Recommended Risk Management Levels Using the Simplified Approach, of the *ARB Risk Management Guidelines for New, Modified, and Existing Sources of Lead*; permits for projects with maximum offsite air concentrations $\leq 0.30 \mu\text{g/m}^3$ are approvable. The 30-day maximum lead air concentration for this project is $0.0024 \mu\text{g/m}^3$ and is approvable.

Location		30-day Maximum Lead Concentration $\mu\text{g/m}^3$

1. All TAC emissions, including H2SO4, from the H2 plant and CCR furnaces were scaled up by a factor of 2.

Chevron Energy Plant and Hydrogen Plant Renewal Project, P#10, A#12842

Table 2 - Acute Hazard Index Results

July 24, 2008

Note: The model output for the maximum acute HI due to the emissions from each sources does not necessarily occur at the same hour or location. Simply summing the maximum individual acute HI results in a value that is higher than that found when analyzing the combined source impacts occurring at the same hour and location.

Source(s)	NAD27 UTM_E	NAD27 UTM_N	Acute Hazard Index	Comment

1. The cancer unit risk values include the impacts from other pathways for multipathway TACs. The URV is derived from HARP for each receptor (residential and worker) and includes exposure adjustments based on the continuous operation of the source.
2. The chronic non-cancer hazard quotient for the residential is not adjusted for exposure. For the worker receptor, the chronic non-cancer hazard quotient for TACs with inhalation only pathways is adjusted for exposure (adjustment = 8/24*245/365) and no exposure adjustment is made to the hazard quotient for multipathway TACs.
3. Includes latest health value changes adopted by OEHHHA for Ethylbenzene, Antimony, Bromine and compounds, Copper, Phosphorus and Zinc.

*** MODEL SETUP OPTIONS SUMMARY ***

-- -- -- -- --
**Intermediate Terrain Processing is Selected
**Model Is Setup For Calculation of Average CONCentration Values.
-- SCAVENGING/DEPOSITION LOGIC --
**Model Uses NO DRY DEPLETION. DDPLETE = F
**Model Uses NO WET DEPLETION. WDPLETE = F
**NO WET SCAVENGING Data Provided.
**NO GAS DRY DEPOSITION Data Provided.
**Model Does NOT Use GRIDDED TERRAIN Data for Depletion Calculations
**Model Uses RURAL Dispersion.
**Model Uses Regulatory DEFAULT Options:
1. Final Plume Rise.
2. Stack-tip Downwash.
3. Buoyancy-induced Dispersion.
4. Use Calms Processing Routine.
5. Not Use Missing Data Processing Routine.
6. Default Wind Profile Exponents.
7. Default Vertical Potential Temperature Gradients.
8. "Upper Bound" Values for Supersquat Buildings.
9. No Exponential Decay for RURAL Mode
**Model Accepts Receptors on ELEV Terrain.
**Model Assumes No FLAGPOLE Receptor Heights.
**Model Calculates PERIOD Averages Only
**This Run Includes: 15 Source(s); 26 Source Group(s); and 4832 Receptor(s)
**Misc. Inputs: Anem. Hgt. (m) = 10.00 ; Decay Coef. = 0.000 ; Rot. Angle = 0.0

*** MODEL SETUP OPTIONS SUMMARY

-- -- -- -- --
**Intermediate Terrain Processing is Selected
**Model Is Setup For Calculation of Average CONCentration Values.
-- SCAVENGING/DEPOSITION LOGIC --
**Model Uses NO DRY DEPLETION. DDPLETE = F
**Model Uses NO WET DEPLETION. WDPLETE = F
**NO WET SCAVENGING Data Provided.
**NO GAS DRY DEPOSITION Data Provided.
**Model Does NOT Use GRIDDED TERRAIN Data for Depletion Calculations
**Model Uses RURAL Dispersion.
**Model Uses Regulatory DEFAULT Options:
1. Final Plume Rise.
2. Stack-tip Downwash.
3. Buoyancy-induced Dispersion.
4. Use Calms Processing Routine.
5. Not Use Missing Data Processing Routine.
6. Default Wind Profile Exponents.
7. Default Vertical Potential Temperature Gradients.
8. "Upper Bound" Values for Supersquat Buildings.
9. No Exponential Decay for RURAL Mode
**Model Accepts Receptors on ELEV Terrain.
**Model Assumes No FLAGPOLE Receptor Heights.
**Model Calculates PERIOD Averages Only
**This Run Includes: 19 Source(s); 31 Source Group(s); and 4832 Receptor(s)
**Misc. Inputs: Anem. Hgt. (m) = 10.00 ; Decay Coef. = 0.000 ; Rot. Angle = 0.0

Chevron Renewal Project

Revision Notes:

1. TAC emission changes at SRUs # 1, 2, 3; H2 Plt Cooling tower hourly; CCR Regen Vent hourly
2. Chronic Inhalation REL has since been removed for Antimony, Bromine and Compounds, Copper, Phosphorus, and Zinc. New Inhalation cancer potency factor adopted for ethyl benzene.
3. Stack parameters were changed for the SRUs #1, #2, #3 (height, diameter and flowrates); CCR vent (height); CCR Furnaces (flowrate); H2 Plt Cooling Tower (diameter); and Cogen #3 (flowrate and diameter).
4. Stack exit velocity was adjusted for the lower flow rates at the SRUs
 - SRU #1: 17,000 to 15000 scfm (30000 acfm @ 600°F)
 - SRU #2: 17,000 to 15000 scfm (30000 acfm @ 600°F)
 - SRU #3: 34,000 to 30000 scfm (60000 acfm @ 600°F)
5. Model run Run_07_24_2008res high.bst was used to get a fine receptor grid around the high found in Run_07_23_20008.bst.
6. Changes allow Cogen#3 to be below TBACT trigger without having to refine the analysis to sum only chronic HIs that affect the same target organ.

INTEROFFICE MEMORANDUM

August 28, 2008

SUBJECT: Revised Hazard Index Assessment for Chevron Products Company,
Richmond, Plant #10, Application #12842, Energy Plant and Hydrogen
Plant Renewal Project

At your request, I have completed a revised hazard index assessment for the above referenced permit application addressing the change in H₂S emissions out the three SRU stacks. H₂S emissions out each of the SRU stacks were scaled up by a factor of 1.33 -- the ratio of the proposed 4 ppm H₂S permit condition limit to the 3 ppm concentration used in the calculation of the H₂S emissions out the SRU stacks for the July 24, 2008 health risk assessment (HRA). All other parameters remain the same as those used in the previous HRA. Results from this assessment indicate that there is no significant change to the maximum chronic hazard index of **0.3**, and the maximum acute hazard index increases from 0.9 to **1.0**. In accordance with the District's Regulation 2, Rule 5, these risk levels are considered acceptable.

Health Weighted Emissions Inputs: H₂S is only one of many toxic air contaminants (TAC) emitted out the SRU stacks. Thus, the change in the health weighted emissions input for each SRU stack is not linearly proportional to the H₂S emissions change. The table below shows the change in the health weighted emissions inputs for the maximum chronic hazard index and the acute hazard index.

Modeled Point	Previous Worker Chronic HI Model Input	Current Worker Chronic HI Model Input	% difference
SRU #1 stack	2.03E-02	2.06E-02	1.5
SRU #2 stack	1.33E-02	1.35E-02	1.5
SRU #3 stack	2.40E-02	2.45E-02	2.1

Modeled Point	Previous Worker Acute HI Model Input	Current Worker Acute HI Model Input	% difference
SRU #1 stack	1.46E-03	1.70E-03	16.4
SRU #2 stack	1.20E-03	1.44E-03	20.0
SRU #3 stack	2.30E-03	2.78E-03	20.9

The TAC emissions from the remaining 16 modeled points remain unchanged. Based on previous modeling, H₂S emissions from the SRU fugitives have a larger impact on the acute hazard index than H₂S emissions out the SRU stacks; this is confirmed in the results of this assessment.

Chevron Energy Plant and Hydrogen Plant Renewal Project, P#10, A#12842

Alhambra, CA 91801
Ph: (626) 382 0001
e-mail: sahuron@earthlink.net

To: Lamont Thompson

From: Ranajit (Ron) Sahu

Date: July 15, 2008

Re: Responses to Technical Issues Raised in CBE Letter of July 9, 2008

As you requested, the following are my responses to a letter from the CBE dated July 9, 2008 regarding, among other topics, CBE's proposed oil cap and about my brief summary of then-proposed Conditions C16 and C17 attached to the June 19, 2008 staff report to the Planning Commission. All page numbers cited, below, are to CBE's letter unless otherwise stated.

(1) Type of Analysis Presented on June 19, 2008

CBE misconstrues the intent of what its letter refers to as the "Sahu Report." My June 19 summary was not intended to be a "complete" analysis of the Project or to substitute for the extensive analyses that support the EIR. It was created to describe to the Planning Commission, in summary form, the rationale for the then-proposed Conditions C16 and C17, which were drafted at in response to a request by the Planning Commission at the June 5, 2008 hearing for the staff to explore creating such conditions. The issues raised in CBE's July 9 letter are addressed in my technical memorandum attached to the July 15, 2008 staff report. Similarly, my summary was not designed to "identify the design specifications of the process equipment" as CBE states (page 6). That is properly done as part of the engineering analysis for the Project. As noted in several documents, there is no expansion of the capacity of the Refinery, except for the ability to process higher sulfur feed-stocks. Since the SDA limit properly limits the Refinery to crude-oil feed-stocks that are no different from current feed-stocks, CBE's "oil-switch" premise lacks support. Therefore, all the expected impacts CBE derives from this assumption also lack support

(2) Content of Sahu Analysis

CBE's criticisms on pages 7 through 10 (dealing with Nickel, Vanadium, Mercury limits, etc.) are moot, because they pertain to proposed Conditions C16 and C17, which were not adopted by the Planning Commission.

First, as explained below, even if these criticisms were pertinent, CBE confuses its own proposed limits and actual reported data. It is customary that there be some nominal compliance margin between a

permit limit or condition and actual measured parametric values. Second, CBE's comparisons between concentrations in proposed Condition C17 and that proposed by CBE are also skewed, because CBE's data are based on relatively short time durations. For example, for its proposed Nickel and Vanadium limits, CBE uses actual data from 2007 only. I believe that there is no basis to arbitrarily select one recent year as representative of past performance. In contrast, I used crude oil assay data (upon which crude procurement decisions are made – and which are typically higher than actual constituent data) for the last decade or so in arriving at my earlier proposed limits in C17.

Regarding mercury, I have not been able to verify the various comparisons that CBE had put forth. Nonetheless, the comparisons suffer from the same problem that was noted above. Namely, they compare the Condition C17's proposed limit with recent, actual data. That the two are different is no surprise. Regarding the mass comparisons, CBE assumes that the proposed limit (which will be greater than actual concentrations) is applied against 365-day operation of the Refinery at maximum throughput conditions (i.e., 243,000 bbl/day) in order to arrive at a maximum potential mercury input of 327 kg/year. However, rather than recognizing that this is a maximum, potential mercury input via crude oil, CBE compares this with actual mercury emissions reported for recent time periods. This is like comparing apples to oranges. CBE's proposal also does not discuss the manner in which the actual mercury measurements were made (i.e., what test methods were used). These can also affect the comparisons. For example, the actual measurement methods for measuring crude oil mercury contents and those reported to agencies (which CBE uses) may be different, accounting for the difference in the concentrations. I was not able to investigate these potential issues that can explain the differences in the time available.

(3) Use of Non-Public Data

I have made it clear from the very beginning of my work for the City on this Project that it was not and is not my preference to use non-public data. I asked for and received data that I felt necessary to provide the technical analysis required by the City.

It is my experience, working with all of my clients (industry, government, public interest groups), that proceedings such as permit approvals and the like often require the proper handling of confidential data. Confidentiality is not intended to keep data from stakeholders, as much as from competitors. In the final analysis, I have used very little confidential data in order to support my analysis – namely the SDA limits for Condition C12. To develop this condition, to evaluate CBE's proposed "feedstock limits", and to develop formerly proposed conditions C16 and C17, I reviewed only two documents that were confidential. One document showed the Refinery's SDA throughput level for the past 10 years. The other document was a spreadsheet containing data on the composition of crude oils used at the Refinery. This spreadsheet contained data on the following parameters for blended crude oil, by month, for a period of roughly the last ten years: API gravity, sulfur, acid number, viscosity, nickel, vanadium, selenium, and mercury.

(4) Consideration of Safety Issues

CBE states that its analysis, which I have supposedly “ignored,” is based “among other things” on the tenet of Inherently Safer Systems in the Industrial Safety Ordinance (“ISO”), and “evidence” that the interactions of acids and other oil quality factors could create inherently hazardous conditions (page 9)

First, I have not ignored CBE’s concerns. I do disagree with CBE, but I came to this conclusion after carefully considering CBE’s comments, and after several meeting and telephone calls with Mr. Greg Karras. While CBE may claim that its analysis is based on the tenet of Inherently Safer Systems, it is my opinion, based on numerous discussions with CBE, that its proposal is based on the Precautionary Principle, which is, simply, the idea that if something is not proven to be safe without any margin of error whatsoever, then it should not be implemented. Inherently Safer Systems are not the same as or synonymous with the Precautionary Principle. I have reviewed the ISO as well as federal regulations relating to Process Safety Management (by OSHA) and Risk Management Plans (by USEPA), upon which the ISO is based. Fundamentally, the ISO, taken as a whole, deals with risk management – namely how to understand, analyze, and mitigate potential risks from industrial processes such as the processes at the Refinery. This involves a whole suite of actions, of which designing Inherently Safer Systems is one. Of course, making a system inherently safer is the starting point for achieving an ultimately safer system. But, constraining a system, without any explicit showing of how such constraints reduce risks, is not technically defensible. Even if one were to accept CBE’s unsupported assumption that the Renewal Project will result in higher levels of contaminants in the Refinery’s input feedstock, CBE’s sole focus on these levels as being directly determinant of the resulting risks is overly simplistic. CBE ignores the value of good engineering design, proper operating practices, robust inspections, timely maintenance, careful analysis of “management of change,” and similar factors in minimizing risk, all of which are also part of the ISO.

Lastly, CBE’s belief that simultaneous constraints on the proposed oil quality parameters, without a fundamental understanding of the interactions among the various parameters is alarmist and counterproductive. For instance, CBE uses the TKC expansion as an example of how emissions may increase in the future. Even if CBE’s assumptions were true, CBE’s analysis does not consider that: (a) based on my conversations with catalyst vendors, the type and volume of the TKC catalyst can accommodate the increased loading of contaminants, and can do so in a manner that minimizes the frequency of planned shutdowns of the TKC for catalyst changes; (b) even if there are shut-downs, the volumes of gases generated can be reduced via flare gas management to a minimum level.

(5) CBE’s Claims are Not Supported

In summary, CBE claims that “The Sahu Report does not rebut publicly verified evidence that a comprehensive oil input quality cap is needed to ensure that significant potential impacts resulting from the Project’s expansion of capacity to refine low quality oils will be lessened or avoided” (page 10). This statement is incorrect for the following reasons:

- (a) Even though CBE has submitted voluminous materials into the record (some of it repeatedly), much of it is irrelevant to the Renewal Project (or, at the very least, its relevance to the Renewal Project is

never made clear by CBE). Nor has CBE provided “publicly verified evidence” for its claims. CBE repeatedly cross references its own previous submissions to strengthen its subsequent statements. This is not “evidence,” nor is it “verification.” It is repetition. I note that CBE’s “evidence” includes, among other items: entire copies of textbooks on refining; crude oil production data from California (even though the Richmond Refinery does not and cannot process California crude oil); numerous examples of crude assay data from all over the world (without any explanation as to how these are relevant to the Refinery); flare reports from other refineries in the Bay Area and elsewhere (although the similarity or dissimilarity of crude slates, design, maintenance, and processing between the Refinery and these refineries is not discussed); incorrect and misleading process diagrams; and misleading figures that serve to confuse rather than to illuminate. In spite of this, I have considered all the submitted information.

(b) CBE never explains what it means by “comprehensive” with regard to its proposed oil quality cap. In addition, CBE’s own “comprehensive” cap proposal has undergone transformations during the last few months. For example, some parameters (such as viscosity) that were originally proposed have been dropped, and at least one parameter (Nickel) was added, based on a conversation with me. CBE’s loose collection of parameters, which CBE titles “comprehensive,” is nothing more than a grab-bag of varying conditions without any fundamental technical support. Significantly, CBE has never provided any kind of analysis of the interactions of these parameters, some of which are counterproductive. For example, simultaneously lowering acid number and sulfur content may actually enhance corrosion, as opposed to reducing it. I strongly believe that staff’s proposed conditions, taken as a whole, are more “comprehensive” and address the likely potential impacts of the Project in a more meaningful and technically supportable manner.

(c) CBE’s description of “significant potential impacts” is based on the assumption that the only way to control emissions from the Refinery is to control the characteristics of the inputs to the Refinery. This is not supportable. The Refinery consists of numerous processing facilities that transform input oil quality parameters. That there is a role for process chemistry, design, operations, maintenance, monitoring, and the like, and that all of these, in combination with input quality, together determine output emissions, is not considered by CBE. The staff’s proposed conditions, on the other hand, address critical parameters from input quality, where needed (i.e., at the SDA) to output monitoring (via mass balance and monitoring) in order to ensure that Project emissions are measured and impacts demonstrated to be minimal.

(d) CBE’s assumption that the Project is an “expansion of capacity” is not demonstrated. It rests on the fact, for example, that the TKC will be expanded to 80,000 bbl/day from its current capacity. However, since all of the TKC product feeds into other units (such as the FCC), whose capacities are not proposed for expansion, this increase in the TKC will not translate into an expansion of Refinery capacity.

(e) Finally, CBE’s assumption that the Project is an expansion of capacity to refine “low quality oils” is also not demonstrated, especially given the constraints created by the proposed conditions, such as C12.

CBE's overarching contention appears to be that there are plenty of crudes (and gas oils, although CBE has not provided evidence of this) that Chevron could procure while meeting CBE's proposed oil quality restrictions and implementing the Project. Even if true, this contention is beside the point. The goal of the City's technical analysis is to determine if there are adverse impacts from the Project as proposed. That has not been demonstrated and the proposed conditions, taken as a whole, ensure against it.

Attachment 1 to Staff Report for June 19, 2008

Rationale for Condition C17
by Dr. Ranajit Sahu (June 16, 2008)

I. Parameters for Crude Oil and Gas Oils

(a) CBE's suggestion to include a specific gravity limit for crude oil is based on the following explanation: "Refining heavier (higher-gravity) oil increases pollution by increasing the amounts of non-floating oil components that cause toxic impacts from oil spills during crude shipments to refineries. Heavier crude is also generally higher in pollutants that are not otherwise covered by the proposed cap, such as other metals and polycyclic aromatic hydrocarbons."¹ First, the SDA limit in Condition C12 assures that heavier crudes will not be used in the Refinery. Second, current practices, including the requirement for Chevron to comply with its Spill Prevention Control and Countermeasure (SPCC) Plan, adequately address the potential for future spills during shipping. I reviewed the total quantity of spills in the last five years due to all product transfers at Chevron's Long Wharf, and found that the spill quantity was negligible – and that a significant amount of these spills did not contact water.

(b) CBE's suggestion to include a limit on total acid number (TAN) for crude oil is based on the following explanation: "Refining higher-acidity oils increases pollution because it increases the incidence of malfunctions from corrosion, resulting in more process upsets, flaring, spills, fires and explosions in refineries." The indirect impact of TAN on pollution due to malfunctions is speculative. It assumes that equipment designers are insensitive to materials compatibility issues. It also assumes that it is in Chevron's economic interests to allow additional malfunctions and thereby longer periods of shutdown. Both of these assumptions are incorrect. I could not determine any factual basis for these assumptions.

(c) CBE's suggestion to include limits on nickel and vanadium in crude oil are similar and are based on the following explanation: "Refining higher-vanadium oil increases pollution by increasing the pollution-intensive processing needed to remove this catalyst poison from the oil, by increasing malfunctions that result in upsets, flaring, spills, fires and explosions and by increasing the amounts of toxic gases that are released when these incidents occur." Also, "[r]efining higher-nickel oil increases pollution by increasing the pollution-intensive processing needed to remove this catalyst poison from the oil, by increasing malfunctions that result in upsets, flaring, spills, fires and

¹ This discussion of the rationale for Condition C17, including Parts I (a) through (e) and Part II, below, is intended to apply to both crude oil and gas oils.

explosions and by increasing the amounts of toxic gases that are released when these incidents occur.”

In each case, the rationale provided is indirect or speculative. Nickel and vanadium-containing oils are processed in the same manner as any other oils. These two metals are preferentially partitioned in the heavier fractions during distillation (for crude oils), and generally end up in the heavier product streams or in catalysts (for gas oils). Catalysts designed for use in refineries are specially designed for handling nickel and vanadium and to function in their presence. I could find no basis for the suggestion that there would be more “pollution-intensive processing” nor could I correlate increased nickel and vanadium levels with “increasing malfunctions.” I have also determined that the Refinery currently processes crude oils and gas oils that can have higher levels of nickel and vanadium than is proposed by CBE as the limit for each. I could find no malfunctions have could be correlated to these metals. I have not been able to substantiate that there will be any additional nickel and/or vanadium increases in crude oil or gas oils beyond current levels after imposition of Conditions C12 and C13 and proposed Condition C17(a).

(d) CBE’s suggestion to limit the amount of selenium in crude oil is based on the following explanation: “Refining high-selenium oil increases pollution by increasing the amounts of this toxic pollutant in refinery waste water discharges. Selenium already violates water quality standards in San Francisco Bay.” Based on its properties, most of the selenium entering the Refinery, via either crude oil or gas oils, partitions into the refinery waste water (i.e., sour water) streams, which are then treated to meet RWQCB limits for the Refinery. I have determined that the Refinery is in compliance with its selenium discharge limits to the Bay. In addition, the Refinery has one of the lowest rates of selenium discharge to the Bay for all of the Bay Area refineries. I have not been able to substantiate that there will be any additional selenium increases in crude oil or gas oils beyond current levels after imposition of Conditions C12 and C13 and proposed Condition C17(a). Nonetheless, given the lack of data for selenium in gas oils, implementing Condition C17(b)(i) will help substantiate the fate of selenium at the Refinery. It is my opinion that Condition C17(b)(i) properly accounts for Refinery operating flexibility in addition to environmental considerations.

(e) CBE’s suggestion to limit the amount of mercury in crude oil is based on the following explanation: “Refining high-mercury oil increases pollution by increasing mercury releases to the environment via on site and off site (products combustion) emissions, water and waste discharges; by increasing workers’ exposures in refineries, and by increasing malfunctions in certain process equipment.” I have reviewed the results of sampling conducted pursuant to requirements by the RWQCB for mercury emissions and levels at the Refinery. I have not been able to substantiate that there will be any additional mercury increases in crude oil or gas oils beyond current levels after

imposition of Conditions C12 and C13 and proposed Condition C17(a) nor have I been able to substantiate mercury impacts on worker exposures or increasing malfunctions. Nonetheless, given the lack of data for mercury in gas oils, Staff is proposing Condition C17(b)(ii) in order to substantiate the fate of mercury at the Refinery. It is my opinion that Condition C17(b)(ii) properly accounts for Refinery operating flexibility in addition to environmental considerations.

II. Running Annual Average Throughput Limits for Process Groups

I have reviewed CBE's suggestion for additional limits, beyond proposed Condition C17(a), to further limit the running annual average throughput limits for specified refinery process groups. I could not determine any additional environmental value to these limits, beyond what would be provided by proposed Condition C17.

APPENDIX E
CEQA FINDINGS DOCUMENT

CHEVRON – RICHMOND REFINERY PROPOSED ENERGY AND HYDROGEN RENEWAL PROJECT

FINDINGS AND SUPPORTING FACTS REGARDING THE ENVIRONMENTAL IMPACT REPORT

Chevron Products Co. (Chevron) has proposed to implement the Energy & Hydrogen Renewal Project (Renewal Project) at its Richmond Refinery (the Refinery). The Renewal Project includes new equipment and modifications to existing equipment that would enable the Refinery to increase energy efficiency and increase equipment reliability.

The Renewal Project includes the following four main components: (1) Hydrogen Plant Replacement, (2) Reformer Replacement, (3) Power Plant Replacement, and (4) Hydrogen Purity Improvement.

The City of Richmond (City) acted as Lead Agency under the California Environmental Quality Act (CEQA) for this project. The City prepared and certified an Environmental Impact Report (EIR) pursuant to the provisions of CEQA. As a responsible agency under CEQA, the Bay Area Air Quality Management District (BAAQMD) participated in the EIR process, including reviewing and commenting on the Draft EIR.

The following timeline illustrates the land use permit application's process by the City:

June 15, 2005: the City issued a Notice of Preparation (NOP) that an EIR would be prepared for the Renewal Project. The NOP was filed with the State Clearinghouse and circulated to governmental agencies and the public for 30 days for review and comment. The City extended this review period until August 25, 2005, for a total of 71 days.

June 23, 2005: A public scoping meeting was held at Richmond City Hall. The City received forty comment letters during the public scoping period.

May 11, 2007: The Draft EIR was published for a 45-day public review period. At the request of members of the public, the City extended the review period until July 9, 2007, for a total review period of 59 days. Various governmental agencies, as well as interested individuals and organizations reviewed the Draft EIR. The City received twenty-eight comment letters and numerous "Stop the Chevron Expansion" postcards during the public comment period.

June 7, 2007: A public hearing was held, to which members of the public were invited by formal public notice to submit comments on the Draft EIR. Twenty-four members of the public commented at this hearing.

November 7, 2007: Chevron submitted to the City an application for a Design Review Permit for the Renewal Project.

January 25, 2008: Volumes 3 through 5 of the Final EIR were published.

February 29, 2008 and April 16, 2008: Chevron submitted suggested findings to the City

March 20, 2008, April 10, 2008, and June 5, 2008: Public hearings held, during which the Final EIR was presented to the City's Planning Commission. Responses to twelve additional comment letters received after the close of the comment period were provided in the City's Staff Report. BAAQMD staff participated.

May 23, 2008: The Consolidated Volume (Volume 6) of the Final EIR was published.

June 19, 2008: The City's Planning Commission certified the Final EIR, which was appealed by Communities for a Better Environment, Asian Pacific Environmental Network, West County Toxics Coalition, Richmond Greens, Richmond Progressive Alliance and Atchison Village Environmental Committee, and by Chevron Products Company.

July 15-17, 2008: The City Council denied appeals by Chevron and Communities for a Better Environment et al., and upheld the City's Planning Commission's decision to approve a Conditional Use Permit and Design Review Permit for the Renewal Project. BAAQMD staff participated.

The Final EIR, which consists of six volumes, did not identify any significant and unavoidable adverse impacts. The Final EIR did identify certain significant or potentially significant environmental impacts that could occur as a result of the Renewal Project. The following discussion summarizes the air quality related effects identified in the Final EIR and during BAAQMD's review of the Chevron Renewal Project permit application, makes one or more of the findings required under Section 15091 of the State CEQA Guidelines, and presents facts to support the findings. These impacts are eliminated or reduced to a less-than-significant level by mitigation measures identified in the Final EIR and made conditions of City approval of the Renewal Project. As the Lead Agency, the City determined that the impacts addressed by these mitigation measures would be mitigated to a less-than-significant level or avoided by incorporation of these mitigation measures into the Renewal Project.

Short-Term Construction Emissions

Activities associated with the Renewal Project construction would generate short-term emissions of criteria pollutants, including suspended and inhalable particulate matter and equipment exhaust emissions, during the term of construction. Implementation of Mitigation Measures 4.3-1a, 4.3-1b, and 4.3-1c, set forth in the Final EIR, adopted and made conditions of the Renewal Project approval by the City, would reduce this impact to a less-than-significant level.

2. Operational Emissions

Operational activities associated with the implementation of the Renewal Project could increase air pollutant emissions. Operational emissions from the Renewal Project would be less than significant with the exception of project-related volatile organic compounds (VOC) emissions, which would be significant. After the publication of the Final EIR, BAAQMD staff suggested

changes to Mitigation Measure 4.3-2a. Implementation of Mitigation Measures 4.3-2a and 4.3-2b, set forth in the Final EIR, adopted and made conditions of the Renewal Project approval by the City, would reduce this impact to a less-than-significant level.

3. Temporary Particulate Matter (PM) Emissions

Alternate phasing of the Renewal Project components could lead to temporary increases in PM emissions greater than significance thresholds. Implementation of Mitigation Measure 4.3-3, set forth in the Final EIR, adopted and made a condition of the Renewal Project approval by the City, would reduce this impact to a less-than-significant level.

4. Greenhouse Gas (GHG) Emissions

Operation of the Renewal Project has the potential to increase the Refinery's output of greenhouse gases by 898,000 metric tons per year carbon dioxide equivalent (CO₂e) emissions. Implementation of Mitigation Measures 4.3-5a through 4.3-5g, set forth in the Final EIR, adopted and made conditions of the Renewal Project approval by the City, would reduce this impact to a less-than-significant-level.

5. Cumulative Construction Emissions

Short-term criteria pollutant emissions associated with the construction of the Renewal Project could result in elevated pollutant concentrations when combined with emissions from other construction projects. This impact is potentially significant. Implementation of Mitigation Measures 4.3-1a and 4.3-1b, and 4.3-1c, set forth in the Final EIR, adopted and made conditions of the Renewal Project approval by the City, would reduce this impact to a less-than-significant level.

6. Cumulative Operational VOC Emissions

Operational emissions of Project-related VOC pollutants could be cumulatively significant. Implementation of Mitigation Measures 4.3-2a and 4.3-2b, set forth in the Final EIR, adopted and made conditions of the Renewal Project approval by the City, would reduce this impact to a less-than-significant level.

7. Cumulative Operational GHG Emissions

Operational emissions of GHG from the Renewal Project, in combination with GHG emissions from other projects in the area, would be cumulatively significant. Implementation of Mitigation Measures 4.3-5a through 4.3-5g, set forth in the Final EIR, adopted and made conditions of the Renewal Project approval by the City, would avoid the Renewal Project's contribution to this impact by reducing the Project's net GHG emissions to zero. The Renewal Project would not, therefore, contribute to a cumulatively considerable impact.

As required by the State CEQA Guidelines, BAAQMD, as a Responsible Agency for the Renewal Project, hereby finds that, for each of the impacts identified in the final EIR and

discussed above, changes or alterations have been required in, or incorporated into, the Renewal Project which avoid or substantially lessen the significant environmental effect as identified in the Final EIR. In addition, for those mitigation measures that are identified in the Final EIR to lessen impacts associated with construction activities and vehicle emissions and that are within the responsibility or jurisdiction of another public agency, BAAQMD hereby finds that such measures either have been or can and should be adopted by such other agency.

In accordance with BAAQMD Rules and Regulations, BAAQMD has fully considered the EIR prepared and certified by the City and has incorporated the EIR's analysis into its decision-making process. BAAQMD granted an Authority to Construct for the proposed project on September 19, 2008.

The documents and other materials that constitute the record of proceedings upon which this decision is based are located at the BAAQMD office at 939 Ellis Street, San Francisco, California, and the custodian of the materials is Rochelle Henderson.

A handwritten signature in blue ink, appearing to read "Jack P. Broadbent", is written over a horizontal line.
