**Table A4.8-CGRP-14
Transit Access Program
Community GHG Reduction Program
Richmond, California**

Assumptions	Value	Units	Sources
Monthly Cost per Participating Pass Holder	\$16	\$/month/participating pass holder	Cost data from the T4T Pilot Program conducted in Contra Costa and Alameda Counties. Total program cost was \$225,000 dollars (includes pass costs and administrative costs) for a total of 1,367 program participants. Of the 1,367 participants, 422 received 6-month passes and 945 received 12-month passes. The cost shown here absorbs the cost for pass holders who chose not to participate in the program. T4T Pilot Project Evaluation: http://www.mtc.ca.gov/planning/smart_growth/tod/T4T/TransLink_for_TOD_Pilot_Project_FINAL.pdf (Accessed December 05, 2013).
Proposed Chevron Subsidy	\$8	\$/month/participating pass holder	Assumes a 50% subsidy.

GHG Emissions Reduction

GHG Emissions Reduction per Month per Participating Pass Holder	34.3	lb/month/participating pass holder	Average GHG savings for a T4T Pilot Program participant based on a total annual program reduction of 475,842 pounds with 422 participants who received 6-month passes and 945 participants who received 12-month passes.
GHG Emissions Reduction per Participating Pass Holder	0.19	MT CO2e/year/participating pass holder	Calculated

Cost Effectiveness Calculation

	Value	Units	Sources

Parameters

	Value	Units	Sources
Sequestration Rate (0 - 5 years)	1.56	MT/acre/year	Euliss, N., Jr., et al. "North American Prairie Wetlands Are Important Nonforested Land-Based Carbon Storage Sites." Science of the Total Environment 361(2006):79–188.
Sequestration Rate (5+ years)	0.34	MT/acre/year	Hansen, L.T. 2009. The viability of creating wetlands for the sale of carbon offsets. Journal of Agricultural and Resource Economics. 34(2): 350-365.

Scenario 1: Includes Land Costs

	Value	Units	Sources
Land Costs and Construction	\$300,000	\$ per acre	Estimate for Northern California
Maintenance Costs	5%	% per year	California Stormwater Quality Association (CASQA). 2003. Constructed Wetlands. In: California Stormwater BMP Handbook, New Development and Redevelopment
Assumed Project Lifetime	25	years	Assumption for cost estimation
Total Cost per Acre	\$660,000	\$ / acre	Calculation
GHG Sequestration over Project Lifetime	14.6	MT/acre	Calculation
Cost Effectiveness	\$45,205	\$/MT CO2e	Calculation

Scenario 2: Assumes Land Available for Free

	Value	Units	Sources
Construction	\$29,000	\$ per acre	Brown and Schueler (1997), The Economics of Stormwater BMPs in the Mid-Atlantic Region: An Examination of the Real Cost of Storm Water Control
Maintenance Costs	\$3,000	\$ / acre / year	
Assumed Project Lifetime	25	years	Assumption for cost estimation
Total Cost per Acre	\$101,000	\$ / acre	Calculation
GHG Sequestration over Project Lifetime	14.6	MT/acre	Calculation
Cost Effectiveness	\$6,918	\$/MT CO2e	Calculation

APPENDIX 4.8 - GOP

GOP: Refinery Operational Greenhouse Gas
Emissions

APPENDIX 4.8-GOP

REFINERY OPERATIONAL GREENHOUSE GAS EMISSIONS

This technical appendix describes the methods and data used to estimate greenhouse gas emissions from operations at the Facility. Greenhouse gases at the Facility include carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O) from on-site stationary combustion and process units as well as indirect emissions associated with purchased electricity and water usage. 2008-2010 period, Baseline, and Project emissions from Refinery Operations are evaluated.¹ The emissions estimation methods described in this appendix follow standard methods approved by the California Air Resources Board (CARB) and the Bay Area Air Quality Management District (BAAQMD), and were developed based on extensive consultation with BAAQMD.

This appendix presents the estimated annual greenhouse gas emissions associated with the Facility equipment described in *Appendix 3, Overview of Oil Refining Process*. Greenhouse gas emissions from transportation-related activities including trucking and rail transport are presented in *Appendix 4.3-TRANS*. Emissions from shipping are presented separately in *Appendix 4.3-SHP*. Emissions associated with construction of the Modernization Project are addressed in *Appendix 4.3-CST*.

This appendix parallels *Appendix 4.3-OP* in that the methodologies used to calculate greenhouse gas emissions from Project-related activities are based on the same analytical building blocks used to calculate criteria air pollutant (CAP) and toxic air contaminant (TAC) emissions. Specifically, Modernization Project emissions are estimated by scaling Baseline emissions based on outputs of the Unit Rate Model (URM), described in *Appendix 4.3-URM*. There are three exceptions that are specific to GHGs, each made in accordance with direction from BAAQMD:

- The 2008-2010 and Baseline greenhouse gas emissions inventories are based on Chevron's mandatory reporting of greenhouse gas emissions to CARB using CARB-specified methodologies, rather than the BAAQMD Emissions

¹ As described in *Section 4.8, Greenhouse Gases*, actual emissions during the 2008-2010 period are referred to as the "2008-2010 period emissions." The term "Baseline" is used to describe the baseline emissions that are adjusted from the "2008-2010 period" to take into account greenhouse gas rule changes and equipment upgrades and changes scheduled to take effect prior to 2016.

Inventory (EI) greenhouse gas estimates. The CARB greenhouse gas emission reports are subject to a verification process by an independent, certified auditor and are thus currently considered more accurate than the greenhouse gas emission estimation formula used in the BAAQMD EI.

- In the Modernization Project emissions inventory, with the exception of the future hydrogen plant, source emission factors are derived from the emissions reported in the CARB greenhouse gas emission reports and 2008-2010 period activities (throughputs) reported for the BAAQMD EI. To obtain Modernization Project emissions, these emission factors are multiplied by the Modernization Project activities (throughputs) calculated by the URM.² For the future hydrogen plant, process greenhouse gas emissions are estimated using methodologies presented in the American Petroleum Institute (API) Greenhouse Gas Compendium (API, 2009). Combustion greenhouse gas emissions from the future hydrogen plant are estimated using the combustion emission factors and methodologies required under the EPA's Mandatory Reporting Rule (Mandatory Greenhouse Gas Reporting, 2012).
- Modernization Project sources of greenhouse gas emissions are only a subset of CAP and TAC emissions sources. Greenhouse gases are generated primarily from fuel combustion, certain greenhouse gas-generating refinery processes, and leaks, whereas CAPs and TACs are generated from those sources as well as additional sources including cooling towers and process and wharf fugitive sources. In short, fewer sources are included in greenhouse gas emission estimates.
- The remainder of this appendix is structured as follows:
 1. Overview of Facility Greenhouse Gas Emission Sources
 2. Overview of Cases Evaluated: 2008-2010 Period, Baseline, and Project
 3. Estimation of Greenhouse Gas Emissions from On-Site Combustion and Process Sources
 4. Estimation of Greenhouse Gas Emissions from Indirect Sources
 5. Estimation of Greenhouse Gas Reductions from Project Design Features and Mitigation Measures
 6. Summary of Facility Greenhouse Gas Emissions
 7. References

² As with the CAP and TAC emissions calculation methodology, greenhouse gas emissions for a subset of sources would not change between the Baseline and the Project because the emissions are independent of production or feedstock type and would remain at the Baseline levels. These sources are described in more detail later in this appendix.

1.1 OVERVIEW OF FACILITY GREENHOUSE GAS EMISSIONS SOURCES

As described in *Chapter 3, Project Description* and *Appendix 3, Overview of Oil Refining Process*, the Facility is a complex industrial facility that processes crude oil blends, externally sourced gas oils, and natural gas into a number of products including motor gasoline, jet fuel, diesel fuel, lubricant base oils, fuel oils, liquefied petroleum gas, and sulfur. The Facility also produces steam and electricity primarily for its own use, and fuel gas and hydrogen solely for its own use. Over 400 individual permitted sources are operated at the Facility, and many are sources of greenhouse gas emissions. There are three categories of greenhouse gas emissions sources at the Facility:

- On-site stationary combustion sources
- On-site stationary process sources
- On-site stationary fugitive sources
- Indirect sources

These categories of greenhouse gas emissions sources are described in more detail in the sections that follow. Table A4.8-GOP-1, below, summarizes the relationships between the refinery operational steps described in *Chapter 3, Project Description* and *Appendix 3, Overview of Oil Refining Process*, and the major Facility plants. The table also identifies the greenhouse gas emissions source category associated with each plant.

1.2 ON-SITE STATIONARY COMBUSTION SOURCES

Combustion occurs when fuel reacts with oxygen in the air to produce energy, usually in the form of heat. CO₂, CH₄, N₂O, and water are byproducts of combustion reactions. In an industrial setting, the heat produced is typically used in the operation of equipment such as furnaces, boilers, process heaters, and engines. These “stationary” combustion sources are differentiated from “mobile” combustion sources such as cars, trucks, and construction vehicles, and equipment.

On-site stationary combustion sources at the Facility include furnaces, boilers, process heaters, internal combustion engines (as part of emergency generators), gas turbines, thermal oxidizers, CAP emission reduction devices, and flares. Furnaces, boilers, and process heaters are devices that provide heat to various liquid or gas streams such as water, process streams (e.g., crude oil), or air. These heating devices all include burner assemblies, where fuel (e.g., natural gas

TABLE A4.8-GOP-1 EMISSIONS ASSOCIATED WITH FACILITY PROCESS STEPS

Process Description	Major Process Unit	Title V Emission Source Categories for Equipment and Components with Air Emissions
Distillation	Crude Atmospheric and Vacuum Distillation Units SDA	Combustion (furnaces) VOC sources (fugitive components) ^c
Treatment to Remove Sulfur and Other Natural Impurities	Hydrotreaters (JHT, NHT, FHT, GHT, DHT) Amine Contactors ^e Amine Regenerators ^e Sour Water Strippers ^e SRU	Combustion (burners, furnaces, thermal oxidizers) Sulfur recovery (hydrogen sulfide plants) Sulfur recovery (Claus Plants [SRU]) Tanks VOC sources (fugitive components) ^c

TABLE A4.8-GOP-1 EMISSIONS ASSOCIATED WITH FACILITY PROCESS STEPS

Process Description	Major Process Unit	Title V Emission Source Categories for Equipment and Components with Air Emissions
	Refinery Fuel Gas System ^b	VOC sources (fugitive components) ^c
	Wastewater Treatment ^c	Wastewater (tanks/API separators, process drains, bioreactor)*
Other Emission Sources	Emergency diesel generators ^c	Internal Combustion Engines ^c
Product Loading ^d	Sulfur loading Wharf loading Marketing rack	Sulfur Recovery (sulfur rack), Loading Terminals (Wharf), Loading Terminals (truck/rail)
Refinery Maintenance Activities	Maintenance Equipment ^e	Cold Cleaners ^c Paint booth ^c

Note: SDA = solvent de-asphalting, JHT = jet hydrotreater, NHT = naphtha hydrotreater, FCC FHT = fluid catalytic cracking feed hydrotreater, GHT = gasoline hydrotreater, DHT = diesel hydrotreater, SRU = sulfur recovery unit, RLOP = Richmond lube oil plant, HNC = heavy neutral hydrocracker, LNC = light neutral hydrocracker, HNF = heavy neutral hydrofinisher, LNF = light neutral hydrofinisher, VOC = volatile organic compound, API = American Petroleum Institute

^a Due to their magnitude, emissions from the boiler plant and cogeneration plant were included in this EIR analysis, despite that there are no anticipated emission increases from these sources resulting from the Modernization Project.

^b Emissions associated with fuel gas system are discussed in the report as furnace combustion emissions.

^c Denotes sources with emissions that are not expected to change as a result of the Modernization Project, and hence were not included in this EIR analysis.

^d Emission reduction devices are used to reduce VOC and carbon monoxide emissions by combusting them to form CO₂. These CO₂ stationary combustion emissions are included in this appendix. Emissions from transportation vehicle exhaust are discussed in *Appendix 4.3-SHP*.

^e Denotes sources that do not generate greenhouse gas emissions, but are included in this table for completeness and consistency with *Appendix 4.3-OP*.

Source: Chevron Title V Permit; Project Description.

or refinery fuel gas) is combusted with oxygen in the air. Internal combustion engines provide mechanical power through the combustion of liquid fuel. Similarly, gas turbines generate electricity through the combustion of gaseous fuel which moves the blades of a turbine, providing mechanical power to operate the electric generator. Thermal oxidizers and the wharf emission reduction devices are used to reduce volatile organic compound (VOC) and carbon monoxide emissions by combusting them to form CO₂.

Finally, Refinery flares are safety devices designed to relieve pressure or to prevent units from over-pressurizing, while at the same time minimizing releases of hydrocarbons directly into the atmosphere. Flares are primarily used for burning off flammable gas released by a relief gas header during either unplanned pressuring of refinery equipment, or during startups and shutdowns. As with other combustion sources, flares produce fuel combustion-related greenhouse gas emissions.

Table A4.8-GOP-2, below, lists the on-site stationary combustion sources included in the Facility greenhouse gas emissions inventories evaluated in this EIR.

^a Source ID corresponds to the ID assigned by the BAAQMD to each emissions source listed on the Facility's current Title V operating permit. For Modernization Project sources not listed in the current Title V operating permit, source IDs from the BAAQMD Authority to Construct permit for the Chevron Hydrogen and Energy Renewal Project (2008 Project) are used.

^b Miscellaneous greenhouse gas sources includes greenhouse gas emissions from the following on-site stationary combustion sources: flares, diesel engines, and miscellaneous natural gas combustion. They also include greenhouse gas emissions from on-site stationary fugitive sources, described in a later section of this appendix.

The methods and data used to estimate greenhouse gas emissions from on-site stationary combustion sources are described later in this appendix.

1.4 ON-SITE STATIONARY PROCESS SOURCES

Certain industrial processes produce greenhouse gas emissions through chemical reactions that do not involve combustion. These emissions are known as process emissions. Examples of industries that generate greenhouse gas process emissions are cement manufacturing, iron and steel production, chemical production, and refineries. On-site stationary process emissions sources at the Facility include the fluid catalytic cracker, sulfur recovery units (SRUs), hydrogen plant, and catalytic reformers (Rheniformers).

In the fluid catalytic cracker unit, the process of catalytic cracking deposits coke byproduct on the fluid catalytic cracker catalyst, which must be removed in order to restore catalytic activity. The catalyst is regenerated by burning off the coke in a controlled combustion process. This process generates CO₂ emissions.

In the sulfur recovery unit, thermal and catalytic processes convert hydrogen sulfide and oxygen into sulfur and water, releasing CO₂ as a by-product.³ Acid gas feed contains some amount of CO₂, and in addition, side reactions convert hydrocarbons into carbonyl sulfide and carbon disulfide intermediates, which are converted to CO₂.

The production of hydrogen from natural gas and/or refinery fuel gas and water involves a series of chemical reactions that produce CO₂ as a by-product. Both the existing hydrogen plant and the future hydrogen plant proposed as part of the Modernization Project are therefore associated with CO₂ process emissions.

Finally, the Rheniformers contain vessels with catalyst that accumulate coke as hydrocarbons are passed over them. This coke must be burned off periodically to regenerate the catalyst, which produces CO₂ emissions.

Table A4.8-GOP-3, below, lists the on-site stationary process emissions sources included in the Facility greenhouse gas emissions inventories evaluated in this EIR.

The methods and data used to estimate greenhouse gas emissions from on-site stationary process sources are described later in this appendix.

³ Some Claus sulfur recovery units have supplementary processes that generate CH₄ emissions; however, per Chevron, the SRU Claus units at the Facility do not have a reboiler vent, and therefore do not release CH₄ emissions.

1.5 ON-SITE STATIONARY FUGITIVE SOURCES

Fugitive greenhouse gas emissions are those that are not discharged to atmosphere in a confined flow stream. Typical fugitive greenhouse gas sources at refineries are leaks from valves, flanges, connectors, pumps, and seals on various equipment storing or processing CH₄-containing materials. Other fugitive greenhouse gas sources are oil/water separators, which may release small amounts of CH₄ from separated oils, and the on-site aerobic treatment of wastewater, which produces small amounts of N₂O.

In this EIR, fugitive greenhouse gas emissions sources are accounted for under Source ID 9998 “Greenhouse Gases from Miscellaneous Storage Tanks” and Source ID 9999 “Miscellaneous Greenhouse Gas Sources,” as shown below in Table A4.8-GOP-4. Source ID 9999 “Miscellaneous Greenhouse Gas Sources” also includes greenhouse gas emissions from certain on-site stationary combustion sources (flares, diesel engines, and miscellaneous natural gas combustion), as noted earlier in Table A4.8-GOP-2.

TABLE A4.8-GOP-4 FACILITY ON-SITE STATIONARY FUGITIVE SOURCES

Source ID	2008-2010 Period and Baseline, Project, or Both?	Source Name
9998	Both	Greenhouse gases from Miscellaneous Storage Tanks
9999	Both	Miscellaneous Greenhouse Gas Sources

The methods and data used to estimate greenhouse gas emissions from on-site stationary fugitive sources are described later in this appendix.

1.6 INDIRECT SOURCES

Chevron purchases and imports public utility electricity from Pacific Gas and Electric Company (PG&E) to provide power, heat, cooling, and lighting for the Facility operations described above as well as the on-site buildings. Chevron also purchases and imports public utility water from the East Bay Municipal Utility District (EBMUD) to support Facility and building operations. Because the greenhouse gas emissions associated with electricity generation and water sourcing, distribution, and treatment are generally produced offsite at sources owned or controlled by another entity, they are considered “indirect” sources of greenhouse gas emissions. Greenhouse gas emissions associated with electricity and water usage are typically generated through the combustion of fossil fuels, which produce CO₂, CH₄, and N₂O emissions. The methods and data used to estimate greenhouse gas emissions from indirect sources are described later in this appendix.

1.7 OVERVIEW OF CASES EVALUATED: 2008-2010 PERIOD, BASELINE, AND PROJECT

Operational greenhouse gas emissions both before and after the Modernization Project is implemented must be evaluated in order to determine the net change in emissions. This EIR evaluates four emissions inventories:

- 2008-2010 Period
- Baseline
- Project 93% Utilization Scenario (Facility 93% Utilization and Hydrogen Plant 100% Utilization)

- Project 100% Utilization Scenario (Facility and Hydrogen Plant 100% Utilization)

This section provides an overview of the key premises for each of the four emissions inventories. Subsequent sections provide more detailed descriptions of the data and calculation methods used to derive the four emissions inventories. Emission inventories for an additional 17 Project scenarios were also evaluated including that for significantly heavier, lighter, and sour blends. These emission inventories are included in Section 1.12.

For the 2008-2010 period inventory, a period of 2008-2010 was chosen because it is representative of existing actual Refinery Operations. As described in *Section 4.8: Greenhouse Gases*, and *Appendix 4.8-BASE*, year 2011 was also reviewed and determined to be consistent with the 2008-2010 period, but is not included in the 2008-2010 period.⁴ 2008-2010 period greenhouse gas emissions for on-site stationary combustion and process sources are obtained from Chevron's reports of greenhouse gas emissions to CARB under the California Mandatory Reporting Rule for Greenhouse Gas Emissions (17 CCR, Sections 95100-95158), as presented in *Appendix 4.8-CEI*. Details of the calculation of Baseline indirect emissions are presented in a later section of this appendix.

The Baseline inventory incorporates: (1) equipment changes; (2) new regulations; and (3) emission reduction measures scheduled to be implemented before the January 2016 expected start date of the Modernization Project. As described in *Section 4.8, Greenhouse Gases*, and *Appendix 4.8-BASE*, the only regulation directly affecting Facility operational greenhouse gas emissions is the California Renewables Portfolio Standard, which requires retail sellers of electric services to increase procurement from eligible renewable resources to 33% of total retail sales by 2020. This gradually decreases the greenhouse gas emission factor for electricity usage and therefore reduces greenhouse gas emissions associated with purchased electricity and water usage in the Baseline. Chevron has identified 13 individual greenhouse gas emission reduction measures that will be implemented after the 2008-2010 period but prior to Modernization Project startup, and are to be implemented independent of the Modernization Project. These include measures that are designed to increase energy efficiency and process performance, thus reducing fuel and electricity usage and associated greenhouse gas emissions in the Baseline. Consistent with the Smart Rail court

⁴ 2012 and 2013 are not representative years for greenhouse gas emissions due to the August 2012 fire that damaged the crude unit. See *Chapter 4.3, Air Quality*, for a more complete description of why 2012 and 2013 are not representative years.

decision described in *Section 4.8, Greenhouse Gases*, this EIR uses the Baseline representing January 2016 conditions to evaluate the significance of Project-related greenhouse gas emissions.

For the Modernization Project emissions inventory, with the exception of the future hydrogen plant, source emission factors are derived from the emissions reported in the CARB greenhouse gas emission reports and 2008-2010 period activities (throughputs) reported for the BAAQMD EI. To obtain Modernization Project emissions, these emission factors are multiplied by the Modernization Project activities (throughputs) calculated by the URM, described in *Appendix 4.3-URM*. For a subset of sources, greenhouse gas emissions would not change between the Baseline and the Project because the emissions are independent of production or feedstock type and would remain at the Baseline levels. These sources are described in more detail later in this appendix. For the future hydrogen plant, process greenhouse gas emissions are estimated using methodologies presented in the API Greenhouse Gas Compendium (API, 2009) while combustion greenhouse gas emissions are estimated using the emission factors and methodologies required under the EPA's Mandatory Reporting Rule (40 CFR, Part 98). Furthermore, two Modernization Project emission inventories are evaluated to represent two different Facility utilization rates.

As discussed in the *Chapter 3, Project Description*, following completion of the Modernization Project, Chevron anticipates operating the Refinery "gateway" units⁵ up to an average annual rate of 93%. Praxair will operate the future hydrogen plant to provide the hydrogen required for Chevron; Praxair is also separately pursuing authorization to export hydrogen to other potential off-site customers such as other refineries, and plans to operate the future hydrogen plant to 100% of its operating capacity if the separate export project is approved. This scenario is evaluated as the Modernization Project – Refinery 93% Utilization and Hydrogen Plant 100% Utilization case (abbreviated as "Project 93% Utilization Scenario"). Chevron is also maintaining its legal right to operate the Refinery at 100% of its permitted capacity (such that the "gateway" units are 100% utilized), which in some circumstances may require nearly all of the Praxair hydrogen plant production capacity. This second scenario is evaluated as the Modernization Project – Refinery and Hydrogen Plant 100% Utilization case (abbreviated as "Project 100% Utilization Scenario").

⁵ As described in *Chapter 4.3 Air Quality*, a refinery "gateway" unit is one that accepts feedstocks from outside the refinery. At the Facility, the gateway units include the crude unit, the fluid catalytic cracker, FCC FHT, RLOP, and several hydrocrackers.

Chevron has committed as a Modernization Project objective to "no net increase" in greenhouse gas emissions for Chevron's Project utilization rate. To achieve this "no net increase" objective, Chevron has proposed several Project Design Features, which are detailed in the sections below.

If greenhouse gas emissions exceed that corresponding to the 93% Utilization Scenario, then additional greenhouse gas emissions reductions will be required to adhere to the "no net increase" commitment. In this case, Chevron shall provide to the City of Richmond a notice that it plans to operate at a utilization rate greater than 93%. If utilization exceeds 93%, Chevron will implement several mitigation measures, which are detailed in the sections below,

The following sections of this appendix provide detailed descriptions of the data and calculation methods used to derive the 2008-2010 period, Baseline, and Modernization Project emissions inventories.

1.8 UNITS OF MEASUREMENT: METRIC TONNES OF CARBON DIOXIDE EQUIVALENT

As described earlier, greenhouse gases at the Facility include CO₂, CH₄, and N₂O from on-site stationary combustion and process units as well as indirect emissions associated with purchased electricity and water usage. The effect each greenhouse gas has on global warming is a combination of the volume of its emissions and its global warming potential (GWP). GWP indicates, on a pound-for-pound basis, how much a gas will contribute to global warming relative to how much warming would be caused by the same mass of CO₂. CH₄ and N₂O are substantially more potent than CO₂, with GWPs of 21 and 310,⁶ respectively.

Greenhouse gas emissions are typically measured in terms of mass of carbon dioxide equivalent (CO₂e). CO₂e is calculated as the product of the mass of a given greenhouse gas and its specific GWP.

Unlike CAPs and TACs which are typically expressed in terms of short tons or pounds, greenhouse gas emissions are typically expressed in terms of metric tonnes (MT). This is the metric used throughout this EIR. Exact totals presented

⁶ These GWPs are from the Second Assessment Report of the Intergovernmental Panel on Climate Change. The more recent Fourth Assessment Report includes different GWPs, but the GWPs from the Second Assessment Report are used by convention, as these values were used to set the Kyoto Protocol system and therefore are contained in this EIR's regulatory assessment.

in all tables and report sections may not equal the sum of components due to independent rounding of numbers.

1.9 ESTIMATION OF GREENHOUSE GAS EMISSIONS FROM ON-SITE STATIONARY COMBUSTION AND PROCESS SOURCES

1.9.1 2008-2010 Period

2008-2010 period greenhouse gas emissions for on-site stationary combustion and process sources were obtained from Chevron's reports of greenhouse gas emissions to CARB under the California Mandatory Reporting Rule for Greenhouse Gas Emissions (17 CCR, Sections 95100-95158), as presented in *Appendix 4.8-CEI*.⁷ Chevron has been reporting its annual greenhouse gas emissions to CARB since 2008 under the Mandatory Reporting Rule, which requires that certain large industrial facilities report their greenhouse gas emissions on an annual basis. Each reporting entity must certify under the penalty of perjury that the emissions statements are accurate. All CARB reports for facilities emitting greater than 25,000 MT CO₂e must also be verified by an independent third party.⁸

As described in *Section 4.8, Greenhouse Gases*, the 2008-2010 BAAQMD EI (which is the basis of the 2008-2010 period CAP and TAC emissions presented in *Section 4.3, Air Quality*) was also evaluated and shown to have a similar Facility greenhouse gas inventory to the CARB reports for the 2008-2010 period. The small differences in totals are due to the BAAQMD inventory relying on a different methodology than the CARB inventory to calculate greenhouse gas emissions associated with the hydrogen plant, and further, the BAAQMD inventory does not include sulfur recovery unit process greenhouse gas emissions or greenhouse gas emissions from sources that are exempt from District permitting. Therefore, the BAAQMD annual emissions totals are typically smaller than those presented in the CARB inventory reports.

Table A4.8-GOP-5, below, provides the CARB and BAAQMD greenhouse gas emissions totals for Facility on-site combustion and process sources for the

⁷ These reports encompass Facility emissions only and do not include indirect, shipping, or other transportation emissions.

⁸ While 2008 emissions were not required to undergo third-party verification, Chevron voluntarily had emissions for that year verified. Third-party verification is a rigorous process that is closely monitored by CARB. Verifiers must undergo training and accreditation through CARB. Conflicts of interest between the verification body and the reporting entity must be cleared before any verification activities may commence.

2008-2010 period as well as year 2011. Year 2011 emissions are included in this table to further indicate that the 2008-2010 period years are typical of operations and 2011 emissions are typically similar to the 2008-2010 period; however, only years 2008-2010 are considered in the 2008-2010 period evaluation.⁹

**TABLE A4.8-GOP-5 2008-2010 AND 2011 BAAQMD EI AND CARB REPORT
TOTAL GREENHOUSE GAS EMISSIONS FOR ON-SITE STATIONARY
COMBUSTION AND PROCESS SOURCES**

Year	BAAQMD EI (MT CO₂e/Year)	CARB Report (MT CO₂e/Year)
2008-2010 Period		
2008	4,060,366	4,798,282
2009	4,283,141	4,522,383
2010	4,226,040	4,511,882
2008-2010 Average	4,189,849	4,610,849
Non-2008-2010 Period		
2011	4,374,532	4,345,277

Note: This table presents refinery operational emissions only, and does not include shipping or other transportation-related emissions, or indirect emissions from electricity and water usage.

Sources: Appendix 4.3-EI; Chevron Data Transmittal #53A, 2013; Chevron Data Transmittal #53B, 2013; Chevron Data Transmittal #53C, 2013. Total Facility emissions reported to CARB for reporting year 2011 are publically available at: <http://www.arb.ca.gov/cc/reporting/ghg-rep/reported-data/ghg-reports.htm>.

Based on the CARB reports, the average annual greenhouse gas emissions from stationary combustion, process, and fugitive sources at the Facility during the 2008-2010 period was 4,610,849 MT of CO₂e. Table A4.8-GOP-6, below, provides the annual average greenhouse gas emissions associated with each stationary combustion and process source at the Facility for the 2008-2010 period. Here, emissions are presented on a per-Source ID basis for consistency with *Appendix 4.3-OP*. As shown in *Appendix 4.8-CEI*, the CARB reports do not present greenhouse gas emissions on a per-Source ID basis, but rather for categories such as Hydrogen Plant Stationary Combustion, Hydrogen Plant Process Emissions, Refinery Fuel Gas Less Hydrogen Plant and Cogeneration Fuel Gas, Refinery Natural Gas Less Cogeneration Natural Gas, SRU Process Emissions,

⁹ 2012 and 2013 are not representative years for greenhouse gas emissions due to the August 2012 fire that damaged the crude unit. See *Section 4.3, Air Quality*, for a more complete description of why 2012 and 2013 are not representative years.

etc. For purposes of this EIR analysis, emissions presented in Table A4.8-GOP-6 are distributed equally among similar Source IDs. For example, overall sulfur recovery unit process emissions as presented in the CARB reports (2008-2010 average) are 7,599 MT CO₂e/year. In the Facility's Title V operating permit, sulfur recovery unit process emissions are associated with three Source IDs representing three sulfur recovery unit trains: 4227, 4228, and 4229. Therefore, in Table A4.8-GOP-6, each of the three Source IDs is attributed one-third of the overall sulfur recovery unit process emissions (2,533 MT CO₂e/year each).

^a Miscellaneous greenhouse gas sources include: natural gas usage other than cogeneration and SRU, diesel engines, flare releases, wastewater treatment, equipment fugitives, oil/water separations, and sulfur hexafluoride.

1.9.2 Baseline

As described earlier, the Baseline inventory incorporates: (1) equipment changes; (2) new regulations; and (3) emission reduction measures scheduled to be implemented before the January 2016 expected start date of the Modernization Project.

The anticipated equipment changes detailed in *Section 4.3, Air Quality* affect CAP and TAC emissions but do not affect greenhouse gas emissions. Therefore, there are no changes to the Baseline greenhouse gas inventory as compared to the 2008-2010 greenhouse gas inventory due to equipment changes.

As described in *Section 4.8, Greenhouse Gases*, the only regulation directly affecting Facility operational greenhouse gas emissions after the 2008-2010 period but before Modernization Project construction and operation is the California Renewables Portfolio Standard, which reduces indirect greenhouse gas emissions from purchased electricity usage and is described later in this appendix under section *Estimation of Greenhouse Gas Emissions from Indirect Sources*.

Therefore, without emission reduction measures, the Baseline emissions from Facility on-site stationary combustion and process sources are the same as the 2008-2010 period emissions: 4,610,849 MT CO₂e/year.

Chevron has identified 13 individual Greenhouse Gas emission reduction measures that will be implemented after the 2008-2010 period but prior to Modernization Project startup, and are to be implemented independent of the Modernization Project. A listing of these measures along with their annualized greenhouse gas emission reductions is provided in Table A4.8-GOP-7. These measures include upgrading motors, improving computer process controls, changing out equipment, repairs, insulation, improvement of catalyst performance, and improved monitoring and maintenance. Many of these measures will reduce greenhouse gas emissions associated with on-site combustion and process sources. Several of the measures will reduce purchased electricity usage and the associated indirect greenhouse gas emissions. Annual savings from each of these measures range from 30,400 MT CO₂e (Improvement to Cogeneration Selective Catalytic Reduction Catalyst Performance and Gas Turbine) down to 10 MT CO₂e (Upgrade of Standard Motors with Premium Efficiency Motors). In total, these measures will result in an annualized savings in greenhouse gas emissions of 74,610 MT CO₂e.

TABLE A4.8-GOP-7 NON-PROJECT FACILITY MEASURES THAT REDUCE GREENHOUSE GAS EMISSIONS

Measure	Emission Reductions (MT CO ₂ e/Year)
Cogeneration Plant - Improvement to Selective Catalytic Reduction catalyst performance and gas turbine resulting in refinery steam savings.	30,400
Cogeneration Plant - Installation of new deaerator feed water preheat coil in the heat recovery steam generators to recover additional waste heat from the gas turbine exhaust resulting in reduced usage of deaerator steam.	19,400
Crude Unit - Online isolation and cleaning of fouled heat exchanger resulting in decreased furnace fuel consumption.	11,300
Rheniformer 5 - Improve furnace heat transfer through use of coating, reducing furnace firing required to heat process stream.	6,700
Facility Furnaces - Install new furnace analyzers for improved monitoring resulting in decreased furnace fuel consumption.	3,500
Naptha Hydrotreating Unit - Install computer process control to improve NHT F-410 furnace operation resulting in decreased furnace fuel consumption.	1,300
Facility - Operation of Diesel Hydrotreater power recovery turbine resulting in electricity savings.	700
#1 Power Plant Boilers - Reduce usage of boilers through improved planning.	300
Facility - Replace steam turbine in fluid catalytic cracker plant with electrical motor resulting in refinery steam savings.	300
Facility - Install new piping and associated pumps and traps to recover hot condensate from steam traps that currently discharge to industrial drains resulting in refinery steam savings.	300
Facility - Operation of Taylor Katalytic Denitrifier power recovery turbine resulting in electricity savings.	200
Facility - Install insulation on uninsulated steam piping to minimize heat loss resulting in refinery steam savings.	200
Facility - Upgrade standard motors with a premium efficiency motors resulting in electricity savings.	10
TOTAL	74,610

Source: Chevron Data Transmittal #25 (Rev #1), 2014.

Ten of the measures that Chevron has completed or has committed to have received rebates under the Statewide Customized Offering for Business program administered by PG&E and overseen by the California Public Utilities Commission (CPUC). These measures constitute up to 70,610 MT CO₂e in annual greenhouse gas reductions or roughly 95% of the total emission reductions that the Facility will implement before 2016. This program creates incentives for energy efficiency projects by providing rebates on permanent capital improvement

projects that demonstrate a real savings in energy. Energy savings from these 10 measures were verified by a third-party consultant that reviews the baseline and post-project energy use as part of a requirement of the program. Baseline energy usage is based on a few years of data; post-project energy usage is based on 6 months of data.

Table A4.8-GOP-8, below, summarizes the Baseline greenhouse gas emissions from on-site stationary combustion and process sources.

Total	4,536,239

1.9.3 Modernization Project

In order to assess Facility operational emissions following Modernization Project construction, three categories of Modernization Project changes to the Baseline must be evaluated.

The first category of emission changes results from physical changes to Facility process units and equipment that will affect emissions (even if it were assumed that there are no changes in utilization and feedstock quality), such as the replacement of the hydrogen plant.

The second category of emission changes results from assuming an increased utilization of the Facility relative to the 2008-2010 period. During the 2008-2010 period, the Facility crude unit operated at an average annual rate of 89% and the existing hydrogen plant operated as needed to produce the level of hydrogen required to process Facility feedstocks. As discussed in the *Chapter 3, Project Description*, following completion of the Modernization Project, Chevron anticipates operating the Facility crude unit and gas oil gateway units at an average annual rate of 93%. Praxair will operate the future hydrogen plant to provide the hydrogen required for Chevron; Praxair is also separately pursuing authorization to export hydrogen to other potential off-site customers such as

other refineries, and plans to operate the future hydrogen plant to 100% of its operating capacity if the separate export project is approved. Chevron is also maintaining its legal right to operate the Refinery at 100% of its permitted capacity, which in some circumstances may require nearly all of the Praxair hydrogen plant production capacity. This second category of emissions relates to the increase in emissions resulting from an increase in Refinery utilization to 93% and 100% (respectively) of the Refinery's permitted capacity, and 100% of the future hydrogen plant capacity. This EIR evaluates 19 Modernization Project emission inventories which include two different Facility utilization rates:

- Project 93% Utilization Scenario (Refinery 93% Utilization and Hydrogen Plant 100% Utilization)
- Project 100% Utilization Scenario (Refinery and Hydrogen Plant 100% Utilization)

The third category of emission changes relates to changes to the quality of the crude and gas oils being processed by the Facility, including heavier crude oils (i.e., lower gravity crude oils) and more “sour” (i.e., higher sulfur content) crude and gas oils. Crude oil sulfur content is increased from 1.58% by weight in the Baseline to 2.5% in the Modernization Project. Gas oil sulfur content is increased from 1.5% in the Baseline to 2.25% in the Modernization Project. The Facility's utilization is affected by the quality of crude oil feedstocks. The Facility's ability to process crude oil that is significantly heavier or lighter than the varying crude oil blends used during the 2008-2010 period is subject to permit-related constraints and equipment limitations. The crude unit divides oil into various “cuts” of differing gravities, and each cut is handled by downstream process equipment. For example, heavier crude oil must be routed to the solvent de-asphalting unit for further processing. The existing permit limit of the solvent de-asphalting is 56,000 barrels/day, but equipment limitations and other factors do not allow the unit to operate at more than 50,000 barrels/day. Significantly lighter crude blends must be processed by the naphtha hydrotreater, which is subject to a permit limit of 57,600 barrels/day. Additional detail on crude oil limitations can be found in *Appendix 4.3-OP*. Thus, if heavier or lighter crude blends are processed, the facility utilization would be lower, which would lead to lower Facility emissions.

These three categories of emissions changes are described in detail in *Section 4.3, Air Quality* and in *Appendix 4.3-OP*. Those documents explain that the three categories of emissions changes are evaluated in the Modernization Project inventory through the use of the URM. The URM is a computer model that was developed to analyze how future crude feedstocks with different fractional characteristics, as well as crude and gas oil feedstocks with different sulfur

content, would affect Facility process unit throughput volumes and production rates. The URM calculations require input values that characterize the crude oil's fractional characteristics and weight, and the sulfur content of the crude and purchased gas oil. Using these input variables, the URM calculates the resulting process unit throughputs, sulfur recovery amount, and hydrogen plant production levels. Process unit throughputs and production volumes generated by the URM are utilized to estimate Modernization Project emissions. The URM is described in more detail in *Section 4.3, Air Quality*, and *Appendix 4.3-URM*. As noted in that chapter the URM assumes the Facility will produce the same kinds of products in roughly the same proportion before and after the Modernization Project. *Appendix 4.3-URM* addresses the effect that the Modernization Project could have on changing the product mix following Modernization Project construction and operation.

Outputs from the URM are sulfur production amount (long tons sulfur per year) for the sulfur recovery unit, hydrogen production level (million standard cubic feet [scf]) per year for the hydrogen plant, and plant throughput (million barrels [MB] per year) for all other combustion and process units. These URM outputs are the “activity metric” used to calculate Modernization Project emissions using the following general equation:

$$E = \text{Activity} \times EF \times C \quad \text{Equation 4.8-GOP-1}^{10}$$

where:

E =	emissions (such as MT CO ₂ e/year)
Activity =	activity metric (such as long tons sulfur/year, million scf hydrogen/year, MB crude/year)
EF =	emission factor (such as MT CO ₂ e/long tons sulfur, MT CO ₂ e/million scf hydrogen, MT CO ₂ e/MB crude)
C =	unit conversion factor, if needed

With the exception of the future hydrogen plant, for each Facility combustion or process source the emission factor in Equation 4.8-GOP-1 above is derived from the emissions reported in the CARB greenhouse gas emission reports¹¹ and 2008-2010 period activities reported in the BAAQMD EI. Specifically, the source's

¹⁰ EF = emission factor.

¹¹ See *Appendix 4.8-CEI: CARB Greenhouse Gas Emissions Inventory*

TABLE A4.8-GOP-9 GREENHOUSE GAS EMISSIONS SOURCES AND UNITS OF SCALING FOR CALCULATION OF PROJECT EMISSIONS

Scaling Unit	Plant
Barrels Fed	Catalytic Reformers Furnaces
	Catalytic Reformer Regeneration
	Crude Unit (Atmospheric and Vacuum) Furnaces
	Fluid Catalytic Cracker Process
	Hydrocracker Furnaces
	Hydrogen Plant Furnaces
	Hydrotreaters (DHT, FCC FHT, GHT, JHT, NHT) Furnaces
	Poly Plant Furnaces
	RLOP (HNC, HNF, LNC, LNF) Furnaces
	SDA Furnaces
Hydrogen Produced	Hydrogen Plant
Sulfur Produced	SRU

Notes: DHT = diesel hydrotreater, FCC FHT = fluid catalytic cracking feed hydrotreater, GHT = gasoline hydrotreater, HNC = heavy neutral hydrocracker, HNF = heavy neutral hydrofinisher, JHT = jet hydrotreater, LNC = light neutral hydrocracker, LNF = light neutral hydrofinisher, NHT = naphtha hydrotreater, RLOP = Richmond lube oil plant, SDA = solvent de-asphalting, SRU = sulfur recovery unit.

CARB-reported 2008-2010 period emissions¹² (in MT CO₂e/year) is divided by the source's 2008-2010 period throughput (in MB/year, long tons sulfur/year, or million scf hydrogen/year) to obtain an emission factor in terms of MT CO₂e/MB, MT CO₂e/long tons sulfur, or MT CO₂e/million scf hydrogen.

Since the Modernization Project is not expected to change the emission factor or emission intensity of any source but the future hydrogen plant, the calculated emission factor for all sources except the future hydrogen plant can be used to calculate Modernization Project emissions. Modernization Project emissions are therefore calculated according to Equation 4.8-GOP-1 above, multiplying the

¹² As described earlier in this appendix, 2008-2010 period emissions are defined as the average of 2008-2010 emissions. Further, on a per-source basis, 2008-2010 period emissions are equivalent to Baseline emissions because there are no equipment or regulatory changes being implemented after the 2008-2010 period but before 2016.

Modernization Project activity obtained from the URM by the calculated emission factor.

For a subset of sources, greenhouse gas emissions are not expected to change with Facility throughput generally, or with Modernization Project changes more specifically. For these sources, emissions are not expected to change between the Baseline and the Modernization Project because the emissions are independent of production or feedstock type and would remain at the Baseline levels. These sources include stationary combustion at the cogeneration plant and power plant, and miscellaneous sources described earlier (including flares, diesel engines, miscellaneous natural gas combustion, equipment fugitives, oil/water separators, and aerobic wastewater treatment). Table A4.8-GOP-10, below, summarizes these sources and provides the reason that no change is expected with the Modernization Project. For these sources, Equation 4.8-GOP-1 can still be used to estimate Modernization Project emissions, but the Activity parameter is the same value for both the Baseline and the Modernization Project calculation.

In summary, for each Facility source except for the future hydrogen plant, Table A4.8-GOP-11 below provides the parameters used in Equation GHG-GOP-1 to calculate Modernization Project emissions: the 2008-2010 greenhouse gas emissions as reported to CARB, 2008-2010 period activity as calculated by the URM based on historical operational data provided by Chevron,¹³ the resulting calculated emission factor, and Modernization Project activity as derived by the URM (for both the 93% and 100% Utilization Scenarios).

The exception to the above scaling methodology is the future hydrogen plant. The future hydrogen plant cannot be scaled from the Baseline emissions, because it uses a different fuel than the existing hydrogen plant.¹⁴ Therefore, greenhouse gas emissions from the future hydrogen plant are estimated using publically available methods, as described below.

¹³ For sources that do not vary with the Project or increased refinery utilization levels, the Adjusted Baseline Activity and Project Activity are both presented as 1.

¹⁴ Unlike the existing hydrogen plant, which produces hydrogen from a process known as “steam reforming,” the future hydrogen plant will utilize pressure swing adsorption technology to produce hydrogen of very high purity. *Chapter 3: Project Description* and *Appendix X, Overview of Oil Refining Process at Chevron Richmond Refinery* provide detailed operational descriptions of the existing and future Hydrogen Plants.

TABLE A4.8-GOP-10 FACILITY SOURCES FOR WHICH PROJECT EMISSIONS ARE EQUAL TO BASELINE EMISSIONS AND DO NOT VARY WITH THE PROJECT OR INCREASED FACILITY UTILIZATION LEVELS

Source Type	Reason for Not Scaling
Component Fugitives	Emissions from process components such as valves and flanges are dependent on the material in the pipe and not flow through the pipe.
Electricity Generation	It is reasonably foreseeable that electricity and steam generation would not be affected by the Modernization Project because of inherent energy efficiencies and power/steam generation from project components.
Flares	Flare pilots operate continuously independently of throughputs. Planned flaring events such as startup and shutdown, as well as emergency flaring events, occur periodically but are also independent of the quantity of Facility throughputs.
Other Product Loading	The unrefined and refined wax loading racks, point orient wharf, asphalt tank truck loading racks, and main tank car loading rack have all been removed from service. The heavy oil trans-loading rack and non-retail gasoline dispensing facility are used internally by Chevron and are not related to Facility throughputs.
Maintenance Shops	Maintenance shops conduct routine operations that are independent of Facility throughputs, and are not expected to increase (and may well decrease) with the modernization of the Facility by the Modernization Project's process unit and equipment modifications.
Portable Storage Containers	These containers are used internally by the Facility for operations not affected by Facility throughputs, and are sealed.
Wastewater Treatment	The volume of wastewater produced in the Modernization Project has been reduced to the same level as the Baseline through Project Design Features, as discussed further in the <i>Section 4.9, Hydrology and Water Quality</i> .

a For Source IDs that only exist in the Project, Baseline emissions and throughputs are taken from the analogous Baseline Source IDs.

b For sources that do not vary with the Project or increased refinery utilization levels, the Baseline activity and Project activity are both presented as 1. Therefore, the emission factor is presented as equivalent to the Baseline emissions in MT CO₂e/year, which are equivalent to the Project emissions.

c The Project emissions presented in this table may not exactly equal the product of the emission factor and throughput, due to independent rounding of numbers.

Process CO₂ emissions¹⁵ from the future hydrogen plant are calculated using the following equation from the API Greenhouse Gas Compendium (API, 2009):

$$E_{CO_2} = FR \times CF \times \frac{44 \text{ mass units } CO_2 / \text{mole}}{12 \text{ mass units } C / \text{mole}} \quad \text{Equation 4.8-GOP-2 (API Equation 5-8)}$$

Where:

E_{CO₂} = annual emissions of CO₂ (tonnes/year)

FR = feedstock rate in units of mass per year (feedstock rate excluding H₂O fed)

CF = weight fraction of carbon in the feedstock

44 = molecular weight CO₂

12 = molecular weight of carbon

In order to use this equation for estimating Modernization Project emissions, it must be modified to scale for different throughputs. First, Chevron provided the feedstock rate and carbon fraction in units of lb-mole rather than mass units (Chevron Data Transmittal #11, 2011). This removes the molecular weight of carbon from the equation. Second, the equation must be modified to account for hydrogen production, since hydrogen produced, as opposed to feedstock rate, is the metric provided by the URM. To do this, the feedstock rate provided by Chevron is divided by the corresponding hydrogen production provided by the URM,¹⁶ and a new term for hydrogen production was added to the equation. The revised equation is as follows:

$$E_{CO_2} = FR' \times URM \times CF' \times 44 \text{ mass units } CO_2 / \text{mole} \quad \text{Equation 4.8-GOP-3}$$

where:

FR' = feedstock rate (lb-mole feedstock / scf hydrogen produced), calculated based on maximum hydrogen production rate (244,000 million scf/day) provided by Chevron (Chevron Data Transmittal #11, 2011).

URM = hydrogen production from the URM (millionscf hydrogen/day), from each URM run). For the Modernization Project, the hydrogen production rate is 244,000 million scf hydrogen/day.

¹⁵ There are no process CH₄ or N₂O emissions associated with Hydrogen Plant operations, only process CO₂ emissions.

¹⁶ Hydrogen production rates for each URM case are presented in *Appendix AQ-URM: Unit Rate Model*.

CF' = mole fraction of carbon in feedstock (lb-mole C/lb-mole feed), provided by Chevron (Chevron Data Transmittal #11, 2011).

Combustion greenhouse gas emissions (CO₂, N₂O, and CH₄) from the future hydrogen plant are calculated based on emission factors from the EPA's Mandatory Reporting Rule (EPA, 2009, Tables C-1 and C-2). In order to scale for hydrogen production in the URM, the emission factors are converted as follows:

$$EF' = EF \times \frac{MF}{H_2} \times 0.11 \times C \quad \text{Equation 4.8-GOP-4}$$

where:

EF' = Adjusted emission factor (lbs/scf hydrogen)
EF = Base emission factor (lbs/million British Thermal Units [BTU]) from EPA Mandatory Reporting Rule
MF = Maximum Permitted firing rate (8,059,200 million BTU/year per furnace, for two furnaces) (Chevron Data Transmittal #21A, 2012)
H₂ = Maximum hydrogen production (million scf hydrogen/day) (Chevron Data Transmittal #11, 2011)
0.11 = Permitted maximum percent of natural gas fired in the future Hydrogen Plant (11%). The other 89% is PSA tail gas. All of the greenhouse gases from the PSA tail gas are accounted for in the process emissions, described earlier (Chevron Data Transmittal #21A, 2012).
C = Unit conversion

Table A4.8-GOP-12, below, presents the greenhouse gas process and combustion emissions from the future hydrogen plant at 100% utilization.

TABLE A4.8-GOP-12 PROJECT GREENHOUSE GAS EMISSIONS FROM THE FUTURE HYDROGEN PLANT

Note:

^a Greenhouse Gas Reduction Measures represents the non-project facility measures that reduce greenhouse gas emissions prior to the operation of the project in 2016.

1.10 ESTIMATION OF GREENHOUSE GAS EMISSIONS FROM INDIRECT SOURCES

Greenhouse gas emissions are produced during electricity generation, typically through the combustion of fossil fuels which produce CO₂, CH₄, and N₂O. Therefore, imported (purchased) electricity¹⁷ used for powering equipment, lighting, space heating, and cooling at the Facility and its on-site buildings are all indirect sources of greenhouse gases. In addition, electricity is required to source, distribute, and treat water used at the Facility, and the emissions associated with this electricity usage are also considered indirect sources of greenhouse gases. These emissions are known as “indirect” because they are produced offsite at sources owned or controlled by another entity, such as the public electricity utility (PG&E) or municipal water provider (EBMUD), but are a result of operations at the Facility.

¹⁷ This is distinct from electricity generated on site. Emissions from electricity generated off site are already included in the Facility’s emissions inventory in its CARB reports.

1.10.1 Purchased Electricity Usage

Indirect greenhouse gas emissions from imported (purchased) electricity usage are calculated using equation 4.8-GOP-1 where the activity is electricity usage in megawatt-hours (MWh)/year and the emission factor is pounds of CO₂e per MWh (e.g., lbs CO₂e/MWh). Since the Facility purchases its electricity from PG&E, PG&E-specific emission factors are used.

Table A4.8-GOP-14, below, shows the activities, emission factors, and greenhouse gas emissions associated with purchased electricity usage for the 2008-2010 period, Baseline, and Modernization Project inventories. The sections below describe the emissions calculations in more detail.

1.10.1.1 2008-2010 Period

Average annual 2008-2010 period electricity usage (MWh/year) is calculated by multiplying the annual average power (MW) provided by Chevron (Chevron Data Transmittal #36I (Rev #2), 2014) by the annual hours of operation (8,760 hours/year in 2009 and 2010 and 8,784 hours/year in 2008 for the leap year). The CO₂ emission factor (MT CO₂/year) is the average of the 2008-2010 emission factors provided by PG&E in its April 2013 report "Greenhouse Gas Emission Factors: Guidance for PG&E Customers" (PG&E, 2013). These historical emission factors are from PG&E's third-party-verified greenhouse gas inventory submitted to the California Climate Action Registry or The Climate Registry. The CH₄ and N₂O emission factors are from the CARB Local Government Operations Protocol Table G.7 (CARB, 2010). Emission factors for the most recent year (2007) are used. The CO₂e emission factor is calculated based on the Intergovernmental Panel on Climate Change (IPCC) GWP as provided in Local Government Operations Protocol Table E.1. The GWP for CO₂, CH₄, and N₂O are 1, 21, and 310, respectively.

1.10.1.2 Baseline

Per Chevron, the Baseline annual average electricity usage is assumed to be equivalent to 2008-2010 period electricity usage (Chevron Data Transmittal #36I (Rev #2), 2014). The CO₂ emission factor is the 2016 emission factor provided by PG&E in its April 2013 report Greenhouse Gas Emission Factors: Guidance for PG&E Customers (PG&E, 2013). The emission factor is calculated using the CPUC Greenhouse Gas Calculator, which factors in projected greenhouse gas reductions under the Global Warming Solutions Act of 2006 (AB 32). The CO₂e emission factor is calculated in the same manner as for the 2008-2010 period calculation.

TABLE A4.8-GOP-14 FACILITY PURCHASED ELECTRICITY USAGE, EMISSION FACTOR, AND ANNUAL GREENHOUSE GAS EMISSIONS

Year	Imported (Purchased) Electricity (MWh/year)	Greenhouse Gas Emission Factors				Greenhouse Gas Emissions from Imported (Purchased) Electricity			
		CO ₂	CH ₄	N ₂ O	CO ₂ e	CO ₂	CH ₄	N ₂ O	CO ₂ e
		(lb / MWh)				(MT/year)			
2008	105,408	641			644.7	30,648	1.4	0.5	30,825
2009	63,072	575	0.029	0.010	578.7	16,450	0.8	0.3	16,556
2010	85,848	445			448.7	17,328	1.1	0.4	17,473
2008-2010 Period Average	84,776	553.7	0.029	0.010	557.4	21,475	1.1	0.4	21,618
Baseline (2016)	84,776	370.0	0.029	0.010	373.7	14,228	1.1	0.4	14,371
Project 93% and 100% Utilization Scenarios (2016)	84,776	370.0	0.029	0.010	373.7	14,228	1.1	0.4	14,371

1.10.1.3 Modernization Project

As indicated by Chevron, annual average electricity usage for the Modernization Project 93% and 100% Utilization Scenarios is not anticipated to change as compared to the 2008-2010 period electricity usage (Chevron Data Transmittal #36I (Rev #2), 2014). The CO₂e emission factor is equivalent to that used in the Baseline.

1.10.2 Purchased Water Usage

Indirect greenhouse gas emissions from water usage are also calculated using Equation 4.8-GOP-1. Here, the activity is water usage in million gallons of water per year. The emission factor is the electricity intensity factor appropriate for Northern California (in units of MWh per million gallons of water) multiplied by the appropriate PG&E electricity emission factor described above (in units of lb CO₂e/MWh) to give an overall emission factor in units of lb CO₂e per million gallons.

Electricity usage and the resulting greenhouse gas emissions associated with water usage arise out of the sourcing, treatment, and distribution of water. Therefore, reclaimed (also known as recycled) water is associated with a lower electricity intensity factor than freshwater (2.1 MWh per million gallons vs. 3.5 MWh per million gallons) because water reclaimed from a process or facility requires less treatment before re-use at another process or facility (CEC, 2006; CAPCOA, 2010). The Facility receives both freshwater and reclaimed water from EBMUD. Details of the annual quantities of each type of water are described in the table and sections below.

Table A4.8-GOP-15, below, shows the activities, electricity intensity factors, electricity emission factors, and greenhouse gas emissions associated with water usage for the 2008-2010 period, Baseline, and Project inventories. The sections below describe the emissions calculations in more detail.

1.10.2.1 2008-2010 Period

Average annual 2008-2010 period freshwater and reclaimed water usage (in million gallons/year) was provided by Chevron (Chevron Data Transmittal #45B (Rev #3), 2014). Consistent with California Energy Commission (CEC) and California Air Pollution Control Officers Association (CAPCOA) methodologies, electricity intensity factors of 3.5 MWh per million gallons and 2.1 MWh per million gallons are used for freshwater and reclaimed water, respectively (CEC, 2006; CAPCOA, 2010). No Facility wastewater is processed by EBMUD (Chevron Data Transmittal #51 (Rev #1), 2013); therefore, energy associated with on-site water treatment is assumed to be accounted for under the stationary combustion

and/or purchased electricity portion of the Facility's greenhouse gas emissions inventory. The same electricity CO₂e emission factor is used as for the 2008-2010 period calculation of indirect greenhouse gas emissions from electricity usage, described earlier. Specifically, the average of 2008-2010 PG&E emission factors is used.

1.10.2.2 Baseline

The average annual Baseline freshwater and reclaimed water usage is assumed to be equivalent to 2008-2010 period water usage. The CEC and CAPCOA electricity intensity factors presented in the 2008-2010 period calculation of greenhouse gas emissions from water usage represent the best available data for future years, so the same electricity intensity factors are used for the Baseline calculation. Further, the same electricity CO₂e emission factor is used as for the Baseline calculation of indirect greenhouse gas emissions from electricity usage, described earlier. Specifically, the 2016 PG&E emission factor is used.

1.10.2.3 Modernization Project

The average annual freshwater and reclaimed water usage for the Modernization Project 93% and 100% Utilization Scenarios was provided by Chevron (Chevron Data Transmittal #45B (Rev #3), 2014). The CEC and CAPCOA electricity intensity factors presented in the 2008-2010 period calculation of greenhouse gas emissions from water usage represent the best available data for future years, so the same electricity intensity factors is used for the Modernization Project calculation. Further, the same electricity CO₂e emission factor is used as for the Modernization Project calculation of indirect greenhouse gas emissions from electricity usage, described earlier. Specifically, the 2016 PG&E emission factor is used.

1.11 ESTIMATION OF GREENHOUSE GAS REDUCTIONS FROM PROJECT DESIGN FEATURES AND MITIGATION MEASURES

1.11.1 Project Design Features

Chevron has committed as a Modernization Project objective to "no net increase" in greenhouse gases for Chevron's Project utilization rate. To achieve this "no net increase" objective, Chevron has proposed the following Project Design Features:

1.11.1.1 Chevron Facility Greenhouse Gas Reductions

Chevron will implement the following measures within the Facility and related Chevron operations. The minimum amount of greenhouse gas reductions to be

TABLE A4.8-GOP-15 FACILITY PURCHASED WATER USAGE, ELECTRICITY INTENSITY FACTOR, ELECTRICITY EMISSION FACTOR, AND ANNUAL GREENHOUSE GAS EMISSIONS

Case	Water Type ^a	Water Usage (million gallons/year)	Electricity Intensity Factor (kWh/million gallons)	Electricity Emission Factor (lb CO ₂ e/MWh)	Annual Greenhouse Gas Emissions from Water Usage (MT CO ₂ e/year)
2008-2010 Period Average	Fresh	2,519	3,500	557.4	2,229
	NRWRP Reclaim	1,424	2,100	557.4	756

Baseline (2016)	Fresh	1,424	3,500	373.7	845
	NRWRP Reclaim	1,424	2,100	373.7	507
	RARE Reclaim	1,241	2,100	373.7	442
	TOTAL	4,088	--	--	1,793
Project 93% Utilization Scenario (2016)	Fresh	1,278	3,500	373.7	758
	NRWRP Reclaim	1,716	2,100	373.7	611
	RARE Reclaim	1,351	2,100	373.7	481
	TOTAL	4,344	--	--	1,849
Project 100% Utilization Scenario (2016)	Fresh	1,351	3,500	373.7	801
	NRWRP Reclaim	1,825	2,100	373.7	650
	RARE Reclaim	1,460	2,100	373.7	520
	TOTAL	4,636	--	--	1,971

Note: ^aWater types provided by EBMUD to the Facility include freshwater, reclaimed water from the North Richmond Water Reclamation Plant (NRWRP) for use in the Facility's cooling towers, and reclaimed water from the Richmond Advanced Recycled Expansion (RARE) Water Project for use in the Facility's boiler feed water applications.

kWh = kilowatt hours

achieved by these Project Design Features is 1,312 MT CO₂e. All reductions will be monitored for verification.

1.11.1.2 Water Conservation

This Project Design Feature would involve the implementation of two Facility water reuse projects which were identified to reduce EBMUD water consumption and wastewater discharge. In aggregate, they are estimated to reduce EBMUD water consumption by as much as 95 million gallons per year.

- Stripped Sour Water Reuse in the Distillation and Reforming Area. Reuse stripped sour water from the sour water concentrator at the existing sulfur recovery unit to supply storage vessel D-852 for use in the distillation and reforming wash water system. This would displace the current use of boiler feed water in the distillation and reforming wash water system. This requires two larger electric pumps at sulfur recovery unit sour water concentrator and/or piping modifications at the distillation and reforming wash water system. The incremental increase in electricity demand from the pumps is 7 kilowatts.

The sulfur recovery unit sour water concentrator uses steam to remove hydrogen sulfide and ammonia from sour water. Stripped sour water is a product of the sulfur recovery unit sour water concentrator. Boiler feed water is tertiary or fresh water that has been further treated to be suitable for use as feed in boilers to produce steam. D-852 is a storage vessel for water to supply water throughout the distillation and reforming area.

- Stripped Sour Water Reuse in the South Isomax Area. Reuse stripped sour water from sour water stripping plants (8 and 18 Plants) to supply storage vessel V-891 for use in the South Isomax process water system. This would displace the use of cold pump condensate in the South Isomax process water system. This requires installation of a heat exchanger at 8 Plant to cool the temperature of the stripped sour water closer to the operating temperature of cold pump condensate.

V-891 is a storage vessel for water which supplies wash water throughout the South Isomax area. cold pump condensate is steam that has been condensed to liquid water and further cooled.

The corresponding electricity savings (from reduced water supply, treatment, distribution and wastewater treatment) were calculated using California Energy Commission default water and wastewater electricity intensities for Northern California (CEC, 2006). The greenhouse gas emissions associated with the incremental increase in electricity demand for the pumps were taken into

account. The reuse of water would result in net greenhouse gas emission reductions of 109 MT CO₂e per year. This was conservatively calculated using a projected electricity emission factor for 2016. The net greenhouse gas emission reduction may be as high as 275 MT CO₂e per year, however, depending on how PG&E reduces its greenhouse gas intensity to meet the RPS requirements.

The projected 2016 greenhouse gas emission factor was calculated based on: (1) the CO₂ emission factor for PG&E projected for 2016; and (2) CH₄ and N₂O emission factors taken from the California Air Resources Board (CARB) (PG&E, 2013; CARB, 2010).¹⁸ The CH₄ and N₂O emission factors were multiplied by their respective GWPs to obtain CO₂e emission factors, then added to the PG&E CO₂ emission factor to obtain a PG&E greenhouse gas emission factor of 0.374 pound of CO₂e per kilowatt hour (lbs CO₂e/kwh). The less conservative emission factor is based on the default emission factor from the CARB Greenhouse Gas Reporting Rule (CCR Section 95111(b)(1)).

1.11.1.3 LED Lighting Retrofits

Chevron shall upgrade approximately 6,000 lighting fixtures with more efficient light emitting diode (LED) lighting, with expected energy reductions of 2,000 MWh per year (MWh/year). Corresponding greenhouse gas emission reductions would be 339 MT CO₂e per year. This was conservatively calculated using an emission factor projected for 2016 (370 lb/MWh) and the CH₄ and N₂O emission factors reported by CARB (PG&E, 2013; CARB, 2010).¹⁹ Greenhouse gas emission reductions may be as high as 857 MT CO₂e/year depending on how PG&E reduces its greenhouse gas intensity to meet the RPS requirements.

1.11.1.4 Marin Clean Energy Participation

Chevron would participate in Marin Clean Energy for Chevron facilities at or co-located to the Facility. Marin Clean Energy is a Community Choice Aggregator under California law that provides lower-CO₂ source electricity to area residents and business within their service area. Marin Clean Energy delivers power via

¹⁸ The CO₂ emission factor is the 2016 emission factor provided by PG&E in its April 2013 report Greenhouse Gas Emission Factors: Guidance for PG&E Customers. The emission factor was calculated using the CPUC greenhouse gas calculator, which factors in projected greenhouse gas reductions under the Global Warming Solutions Act of 2006 (AB 32). The CH₄ and N₂O emission factors are from the CARB Local Government Operations Protocol Table G.7. Emission factors for the most recent year (2007) were used. The CO₂e emission factor was calculated based on the IPCC GWP as provided in Local Government Operations Protocol Table E.1. The GWP for CO₂, CH₄, and N₂O are 1, 21, and 310, respectively.

¹⁹ Ibid.

PG&E, which continues to maintain the power transmission and distribution infrastructure, deliver electricity and handle billing. The electricity Marin Clean Energy customers receive is deemed 50% to 100% renewable energy. By offering a much higher percentage of renewable energy than is available from PG&E, Marin Clean Energy lowers customers' greenhouse gas emissions associated with electricity generation.

Chevron's participation in Marin Clean Energy would be inclusive of its commercial and, if practicable, industrial accounts at Richmond (Weisz, 2014). Commercial and industrial accounts provide 100 MWh and 85,000 MWh per year of electricity to Chevron facilities (Chevron Data Transmittal #47B (Rev #3), 2014). Implementation of this Project Design Feature would reduce greenhouse gas emissions by 0.3 MT CO₂e per year for commercial accounts and 288 MT CO₂e per year for industrial accounts based on conservative calculations (MEA, 2013; PG&E, 2013).²⁰ Greenhouse gas emission reductions may be as high as 26 MT CO₂e per year for commercial accounts and 22,308 MT CO₂e per year for industrial accounts depending on how PG&E reduces its greenhouse gas intensity to meet the RPS.

1.11.1.5 Fluid Catalytic Cracker Cooling Water Tower Motor Upgrade

Chevron would upgrade the motors which drive the cooling fans in the fluid catalytic cracker cooling water tower to adjustable speed direct drive cooling tower motors. In the existing configuration, all fans are driven by single speed (the motor is either on or off) induction motors through right angle gearboxes. Since the cooling water tower typically operates at a fraction of its design capacity, electricity can be saved by using adjustable speed motors. The use of direct drive systems also improves energy efficiency by eliminating the losses in the mechanical translation of energy in the existing right angle gearbox assemblies. This Project Design Feature is estimated to reduce electricity consumption by 3,400 MWh/year (Chevron Data Transmittal #47B (Rev #3), 2014), which corresponds to a reduction in 576 MT CO₂e per year based on

²⁰ The greenhouse gas savings was calculated by multiplying 100 MWh/year of electricity usage by the difference between the PG&E 2016 emission factor (374 lbs CO₂e/MWh) and the estimated Marin Clean Energy 2016 emission factor (366 lbs CO₂e/MWh), which represents the greenhouse gas savings per MWh achieved by switching from PG&E to MCE electricity deliveries. Only the Marin Clean Energy 2011 emission factor (389 lbs CO₂e/MWh) is publically available; therefore, the Marin Clean Energy 2016 emission factor was estimated by applying the same percent reduction that is reported by PG&E for the same years (a 6% reduction from 2011 to 2016).

conservative calculations (PG&E, 2013; CARB, 2010).²¹ Greenhouse gas emission reductions may be as high as 1,457 MT CO₂e per year depending on how PG&E reduces its greenhouse gas intensity to meet the RPS.

1.11.1.6 Community Greenhouse Gas Reduction Programs

See *Appendix 4.8-CGRP* for a description of the CGRPs and associated greenhouse gas reductions.

1.11.1.7 Cap and Trade Allowances and Supplemental Greenhouse Gas Reduction Fund

- A detailed discussion of how Chevron will use cap-and-trade allowances to meet its commitment to “no net increase” and pay into a supplemental greenhouse gas reduction fund is included in *Section 4.8, Greenhouse Gases*.

Chevron's Project Design Features are included as part of the Modernization Project, and will be monitored and tracked as conditions of Modernization Project approval as described further in *Section 4.8.6, Mitigation Monitoring and Reporting*.

1.11.1.8 Summary of Greenhouse Gas Reductions from Project Design Features

Table A4.8-GOP-16 summarizes the greenhouse gas emission reductions from these supplemental Project Design Features.

1.12 SUMMARY OF FACILITY GREENHOUSE GAS EMISSIONS

Table A4.8-GOP-17 summarizes the 2008-2010 period, Baseline and Project Facility greenhouse gas emissions without Project Design Features. Emissions are presented for the four reasonably foreseeable crude blends, which are analyzed at both the 93% and 100% utilization levels, with each case presented both with and without full hydrogen plant utilization. In addition, the maximum utilization for significantly heavier, lighter, or sour blends is also presented. Total

²¹ The CO₂e reduction was calculated using the 2016 emission factor provided by PG&E in its April 2013 report Greenhouse Gas Emission Factors: Guidance for PG&E Customers. The emission factor was calculated using the CPUC greenhouse gas calculator, which factors in projected greenhouse gas reductions under the Global Warming Solutions Act of 2006 (AB 32). The CH₄ and N₂O emission factors are from the CARB Local Government Operations Protocol Table G.7. Emission factors for the most recent year (2007) were used. The CO₂e emission factor (373.7 lb CO₂e/MWh) was calculated based on the IPCC GWP as provided in Local Government Operations Protocol Table E.1. The GWP for CO₂, CH₄, and N₂O are 1, 21, and 310, respectively.

TABLE A4.8-GOP-16 FACILITY PROJECT DESIGN FEATURE EMISSION REDUCTIONS

Project	Annual Greenhouse Gas Emission Reduction (MT CO₂e)
Water Conservation	109
LED Lighting Retrofits	339
Marin Clean Energy Participation	288
Fluid Catalytic Cracker Cooling Water Tower Motor Upgrade	576
Community Greenhouse Gas Reduction Programs	5,500
Cap-and-Trade Allowances and Local Greenhouse Gas Reduction Fund	718,767
Total	725,579

emissions, including transportation are presented in the table. Details on transportation emissions calculations can be found in *Appendix 4.3-SHP* and *Appendix 4.3-TRANS*.

APPENDIX 4.8 - REG

REG: Greenhouse Gas Regulations

APPENDIX 4.8

REG: GREENHOUSE GAS REGULATIONS

Climate change has relatively recently become widely recognized as a threat to the global climate, economy, and population. As a result, the climate change regulatory setting—at the international, federal, state, regional, and local levels—is complex and evolving. This section identifies key legislation, executive orders, and seminal court cases related to climate change that are germane to the Modernization Project greenhouse gas (GHG) emissions.

The regulatory setting is particularly relevant in evaluating (GHG) impacts for California Environmental Quality Act (CEQA) purposes because legal and regulatory requirements, as well as other policies and initiatives, restrict GHG emissions and reduce them gradually over time. This evolving regulatory regime in turn factors into the analysis of the Baseline against which Project impacts are evaluated to make a significance determination under CEQA.

1.1 INTERNATIONAL PROVISIONS

The Kyoto Protocol, adopted on December 11, 1997, is an international agreement that is linked to the United Nations Framework Convention on Climate Change (UNFCCC, 1998). It sets targets and timetables for 37 industrialized countries and the European community for reducing GHG emissions. The targets amount to an average of 5% reduction against 1990 levels over the 5-year period from 2008 to 2012.

Negotiations after Kyoto have continued in an attempt to address the period after the first “commitment period” of the Kyoto Protocol concluded at the end of 2012. In Durban, South Africa, in 2011, parties to the protocol agreed in principle to negotiate a new comprehensive and legally binding climate agreement by 2015 and to enter it into force for all parties from 2020. However, significant divisions remain in determining the parameters of any such new protocol, including its enforcement mechanisms and the degree to which developing economies will begin to be subject to binding emissions targets.

1.2 FEDERAL PROVISIONS

Although the U.S. is not a party to the Kyoto Protocol, in 2002, President George W. Bush set a national policy goal of reducing the GHG emission intensity (tons of GHG emissions per million dollars of gross domestic product) of the U.S. economy by 18% by 2012 (NOAA, 2002). The goal did not establish binding reduction mandates. Rather, the U.S. Environmental Protection Agency (EPA)

began to administer a variety of voluntary programs and partnerships with industries that produce and use synthetic gases to reduce emissions of particularly potent GHGs.

1.2.1 US Supreme Court Ruling in *Massachusetts et al. v. Environmental Protection Agency*

The Bush Administration's approach to addressing climate change was challenged in *Massachusetts et al. v. Environmental Protection Agency*, 549 U.S. 497 (2007). In this decision, the U.S. Supreme Court held that the EPA was authorized by the Clean Air Act to regulate carbon dioxide (CO₂) emissions from new motor vehicles. The court did not mandate that the EPA enact regulations to reduce GHG emissions, but found that the only instances in which the EPA could avoid taking action were if it found that GHGs do not contribute to climate change or if it offered a "reasonable explanation" for not determining that GHGs contribute to climate change.

1.2.2 Endangerment Finding

On December 7, 2009, the EPA Administrator issued an "endangerment finding" and a "cause or contribute finding" under Section 202(a) of the Clean Air Act, concluding that GHGs threaten the public health and welfare of current and future generations and that motor vehicles contribute to GHG pollution.

These findings do not impose any requirements on industry or other entities. However, this action was a prerequisite to finalizing the EPA's proposed GHG emissions standards for light-duty vehicles (EPA, 2009; EPA, 2010; and DOT, 2010) and provided the basis for adopting new national regulations to mandate GHG emission reductions under the federal Clean Air Act.

1.2.3 EPA Rulemaking

The following sections summarize EPA's recent regulatory activities with respect to various types of GHG sources.

1.3.1.1.1 Stationary Sources

This section describes EPA's recent regulatory activities with respect to stationary sources, which are sources of pollutants that do not move from one location. The Chevron Refinery is a stationary source. Other examples of stationary sources include power plants, gas stations, incinerators, boilers, and houses.¹

¹ Houses use electricity for lighting, space heating and cooling, and potable water conveyance. Greenhouse gas emissions associated with the generation and transmission

1.3.1.1.2 *Mandatory Reporting Rule*

Congress passed “The Consolidated Appropriations Act of 2008” (HR 2764) in December 2007, requiring reporting of GHG data and other relevant information from large emission sources and suppliers in the United States. The rule is referred to as 40 CFR Part 98 – Greenhouse Gas Reporting Program (GHGRP). The stated purpose of the rule is to collect accurate and timely GHG data to inform future policy decisions. Facilities that emit 25,000 metric tonnes of GHGs or more per year are required to submit annual reports to EPA. Suppliers of certain products that result in GHG emissions if released and facilities that inject CO₂ underground for geologic sequestration are also subject to the rule.

This program is expected to cover approximately 85% of the nation’s GHG emissions and applies to roughly 10,000 facilities, including the Chevron Richmond Facility. The EPA’s new reporting system will provide a better understanding of GHG sources and will guide development of policies and programs to reduce emissions. The data also will allow the reporters to track their own emissions, compare them to similar facilities, and aid in identifying cost-effective methods to reduce GHG emissions in the future.

1.3.1.1.3 *Tailoring Rule*

In May 2010, the EPA issued the “Tailoring Rule” establishing permitting requirements for GHG emissions under the Prevention of Significant Deterioration (PSD) and Title V Operating Permit programs. A determination of the Best Available Control Technology (BACT) for GHGs is a requirement established by the program in the same manner as it is done for any other PSD regulated pollutant. The Tailoring Rule sets thresholds for GHG emissions that define when permits under the PSD and Title V Operating Permit programs are required for new and existing industrial facilities. This rule generally establishes that first-time new construction projects that emit GHG emissions of at least 100,000 tons per year and modifications at existing facilities that increase GHG emissions by at least 75,000 tons per year are subject to PSD. The rule also establishes that facilities that emit or have the potential to emit at least 100,000 tons per year CO₂e will be subject to Title V permitting requirements. Each new source or modified emission unit subject to PSD is required to undergo a BACT review.

of electricity are known as indirect greenhouse gas emissions. Regulatory actions to reduce indirect greenhouse gas emissions from electricity usage are described in more detail in *Section 4.6, Energy*.

1.3.1.1.4 *U.S. Supreme Court Review of GHG Regulations for Stationary Sources*

On October 15, 2013, the U.S. Supreme Court granted certiorari to address the permissibility of the EPA's determination that its regulation of GHG emissions from new motor vehicles triggered a statutory requirement for the EPA to regulate GHG emissions from stationary sources. Petitioners assert that the trigger for the EPA to regulate GHG emissions from stationary sources should be whether the EPA has promulgated a National Ambient Air Quality Standard for GHGs, instead of whether GHGs are regulated under any provision of the Clean Air Act. If the Supreme Court determines that the proper trigger for stationary source GHG regulation has not yet occurred, it would have potentially significant implications for the EPA's current stationary source GHG permitting rules (e.g., Tailoring Rule) under the PSD and Title V programs. The Supreme Court's decision is expected by early summer of 2014.

1.3.1.1.5 *Climate Action Plan and New Power Plants*

In June 2013, President Barack Obama issued a Climate Action Plan to reduce carbon pollution. The Climate Action Plan established a multi-faceted approach to reduce carbon pollution, ranging from calling for carbon pollution standards for new and existing power plants, to new federal funding for renewables, to directing the development of new efficiency standards for appliances and federal buildings, among other measures.

In accordance with the President's Climate Action Plan, the EPA issued a new proposal on September 20, 2013 for a rule under Section 111 of the federal Clean Air Act establishing the first carbon pollution standards for new power plants. The EPA's proposed rule would set separate standards for natural gas-fired stationary combustion turbines and for fossil fuel-fired utility boilers and integrated gasification combined cycle units. The standards limit CO₂ emissions to between 1,000 and 1,100 pounds CO₂ per megawatt-hour electricity generated, depending on the type and size of the unit. As proposed, the new source performance standard would not apply to currently operating power plants or permitted plants that began construction before September 20, 2013. It also would not apply to units undergoing modification or to reconstructed units, to liquid oil-fired stationary combustion turbine electric utility generating units, to low capacity factor units that sell less than one-third of their power to the grid, or to plants that do not burn fossil fuels (e.g., plants that burn only biomass). The public comment period for the proposed regulation closes 60 days after the date of publication of the proposed rule in the Federal Register (EPA, 2013a; EPA, 2013b).

1.3.1.1.6 *Mobile Sources*

This section describes the EPA's recent regulatory activities with respect to mobile sources, which include vehicles that operate on roads and highways as well as non-road vehicles, engines, and equipment. Examples of mobile sources include cars, trucks, construction equipment, lawn mowers, railroad locomotives, ships, and airplanes.

1.3.1.1.7 *Corporate Average Fuel Economy*

First enacted by Congress in 1975 as part of the 1975 Energy Policy Conservation Act in response to the 1973-1974 oil crises, Corporate Average Fuel Economy (CAFE) standards seek to reduce energy consumption by increasing the fuel economy of passenger cars and light-duty trucks. The CAFE regulation requires each car manufacturer to meet a standard for the sales-weighted fuel economy for the entire fleet of vehicles sold in the U.S. in each model year. Fuel economy, expressed in miles per gallon (mpg), is defined as the average distance traveled by an automobile (in miles) per gallon of gasoline or equivalent amount of other fuel. The National Highway Traffic Safety Administration (NHTSA) of the U.S. Department of Transportation (DOT) administers the CAFE program, and the EPA provides the fuel economy data. NHTSA sets fuel economy standards for passenger cars and light-duty trucks sold in the U.S. while the EPA calculates the average fuel economy for each manufacturer.

1.3.1.1.8 *EPA and NHTSA Joint Rulemaking for Vehicle Standards*

In response to a *U.S. Presidential Memorandum Regarding Fuel Efficiency Standards* dated May 21, 2010, the EPA and NHTSA are taking coordinated steps to enable the production of a new generation of clean vehicles, through reduced GHG emissions and improved fuel efficiency from on-road vehicles and engines. In April 2010, the EPA and NHTSA issued a Final Rulemaking establishing new federal GHG and fuel economy standards for model years 2012 to 2016 passenger cars, light-duty trucks, and medium-duty passenger vehicles. The agencies extended the national program of harmonized GHG and fuel economy standards to model years 2017 through 2025 in a joint Final Rulemaking issued on August 28, 2012. These standards are projected to achieve a fleet-wide average CO₂ emission level of 163 grams per mile in model year 2025. (This would be equivalent, on a mpg-equivalent basis, to 54.5 mpg if all of the CO₂ emissions reductions were achieved with fuel economy technology.)

In addition, on August 9, 2011, the EPA and NHTSA finalized regulations to reduce GHG emissions and improve fuel efficiency of medium- and heavy-duty vehicles, including large pickup trucks and vans, semi-trucks, and all types and sizes of work trucks and buses. The regulations incorporate all on-road vehicles

rated at a gross vehicle weight at or above 8,500 pounds, and the engines that power them. Under the regulations, fuel economy will be improved and GHG emissions will be reduced in model years 2014-2018.

1.2.4 Additional Federal GHG Rules and Policies

In addition to the rules and regulations developed with respect to stationary and mobile sources, discussed above, various other federal developments have occurred that aim to reduce GHGs from other sources, including land use activities.

1.3.1.1.9 Energy Independence and Security Act

On December 19, 2007, President Bush signed the Energy Independence and Security Act (EISA) of 2007. Among other key measures, the EISA would do the following, which would aid in the reduction of national GHG emissions:

1. Increase the supply of alternative fuel sources by setting a mandatory Renewable Fuel Standard (RFS) requiring fuel producers to use at least 36 billion gallons of biofuel in 2022.
2. Set a target of 35 mpg for the combined fleet of cars and light trucks by model year 2020, and direct NHTSA to establish a fuel economy program for medium- and heavy-duty trucks and create a separate fuel economy standard for work trucks.
3. Prescribe or revise standards affecting regional efficiency for heating and cooling products, procedures for new or amended standards, energy conservation, energy efficiency labeling for consumer electronic products, residential boiler efficiency, electric motor efficiency, and home appliances.

Additional provisions of the EISA address energy savings in government and public institutions, promotion of research for alternative energy, additional research in carbon capture, international energy programs, and the creation of “green jobs.”

1.3.1.1.10 American Recovery and Reinvestment Act

On February 17, 2009, President Obama signed the American Recovery and Reinvestment Act (ARRA) of 2009. ARRA was passed in response to the economic crisis of the late 2000s, with the primary purpose to maintain existing jobs and create new jobs. Among the secondary objectives of ARRA was investment in “green” energy programs, including funding the following through grants, loans, or other funding; private companies developing renewable energy technologies; local and state governments implementing energy efficiency and clean energy programs; research in renewable energy, biofuels, and carbon capture; and

development of high efficiency or electric vehicles (The Recovery Act, 2009; EPA, 2009).

1.3.1.1.11 *Renewable Fuel Standards (RFS1 and RFS2)*

Created under the Energy Policy Act of 2005, the RFS program established the first renewable fuel volume mandate in the United States. The original RFS program (RFS1) required 7.5 billion gallons of renewable fuel to be blended into gasoline by 2012. Under the EISA of 2007, the RFS program was expanded to include diesel and to increase the volume of renewable fuel required to be blended into transportation fuel from 9 billion gallons in 2008 to 36 billion gallons by 2022. In addition, it requires the EPA to apply lifecycle GHG performance threshold standards to ensure that each category of renewable fuel emits fewer GHGs than the petroleum fuel it replaces.

In January 2011, the EPA established the volume requirements and associated percentage standards that applied in calendar year 2011 for cellulosic biofuel, biomass-based diesel, advanced biofuel, and total renewable fuel (RFS2). The final percentage standard sets 8% of renewable fuel per total volume. The rule also announced the 2011 price for cellulosic biofuel waiver credits (\$1.13 per credit) and the EPA's assessment of the aggregate compliance provision for domestic feedstocks. The regulation increased the volume of fuel required to be blended into transportation fuel from 12.2 billion gallons in 2009 to 74 billion gallons by 2022; this includes 16.0 billion gallons for cellulosic biofuel, at least 1 billion gallons for biomass-based diesel fuel, 21.0 billion gallons for advanced biofuel, and 36.0 billion gallons for renewable fuel.

1.3.1.1.12 *Council on Environmental Quality National Environmental Policy Act Guidelines on GHGs*

On February 18, 2010, the White House Council on Environmental Quality (CEQ) published draft guidance on the consideration of GHGs and climate change for National Environmental Policy Act (NEPA) analyses (Sutley, 2010). It recommends that proposed federal actions that are reasonably expected to directly emit 25,000 metric tonnes of CO₂e per year should prepare a quantitative and qualitative NEPA analysis of direct and indirect GHG emissions.

The draft guidance provides reporting tools and instructions on how to assess the effects of climate change. The draft guidance does not apply to land and resource management actions, nor does it propose to regulate GHGs. CEQ received public comment on this guidance for 90 days. Although CEQ has not yet issued final guidance, various NEPA documents are beginning to incorporate the approach recommended in the draft guidance.

1.2.5 Voluntary Programs

The following voluntary programs developed by the EPA provide opportunities for industry, the EPA, and other organizations in both the public and private sectors to work together to reduce GHG emissions (EPA, 2013d).

1.3.1.1.12.1.1.1 Center for Corporate Climate Leadership

The EPA's Center for Corporate Climate Leadership serves as a resource center for all companies looking to expand their work in the area of GHG measurement and management.

1.3.1.1.13 Combined Heat and Power Partnership

The Combined Heat and Power (CHP) Partnership is a voluntary program to reduce the environmental impact of power generation by promoting the use of CHP, which is an efficient, clean, and reliable approach to generating power and thermal energy from a single fuel source.

1.3.1.1.14 Green Power Partnership

The Green Power Partnership is a voluntary partnership between the EPA and organizations that are interested in using green power, which is electricity produced from a subset of renewable resources, such as solar, wind, geothermal, biomass, and low-impact hydropower.

1.3.1.1.15 National Clean Diesel Campaign

The EPA's National Clean Diesel Campaign (NCDC) promotes diesel emission reduction strategies. The NCDC works to reduce the pollution emitted from diesel engines across the country through the implementation of varied control strategies by working with manufacturers, fleet operators, air quality professionals, environmental and community organizations, and state and local officials to reduce diesel emissions. NCDC activities include developing new emissions standards for locomotive and marine diesel engines; and promoting the reduction of emissions for existing diesel engines, including using cleaner fuels, retrofitting and repairing existing fleets, and reducing idling, among others.

1.3.1.1.16 State and Local Climate and Energy Program

The EPA also administers the State and Local Climate and Energy Program, which provides technical assistance, analytic tools, and outreach support to state, local, and tribal governments (EPA, 2013c).

1.3 MULTI-STATE AREA PROVISIONS

The Western Regional Climate Action Initiative (WCI) was established in 2007 by the governors of five U.S. states (Arizona, California, New Mexico, Oregon, and Washington) as a partnership to implement a regional, economy-wide cap-and-trade system to reduce global warming pollution. By the end of 2008, the partnership had expanded to include Montana, Utah, and four Canadian provinces (British Columbia, Manitoba, Ontario, and Quebec).

The WCI partners set a goal of reducing the region's GHG emissions from the electricity, industrial, and transportation sectors to 15% below 2005 levels by 2020. By December 2011, California and Quebec had adopted cap-and-trade regulations based on WCI recommendations, while the rest of the partner states declined to actively implement a cap-and-trade program. The partnership was then streamlined to include only California and the four Canadian provinces actively implementing or considering cap-and-trade programs. In May 2013, CARB adopted a final rule linking California's and Quebec's cap-and-trade programs (as of January 1, 2014) for the purpose of allowing the two entities to mutually recognize each other's compliance instruments. In October 2013, California and Quebec entered into an agreement to integrate and harmonize their cap-and-trade programs.

1.4 CALIFORNIA PROVISIONS

California has adopted various administrative initiatives and also enacted a variety of legislation relating to climate change, much of which sets aggressive goals for GHG emissions reductions within the state. However, none of this legislation provides definitive direction regarding the treatment of climate change in environmental review documents prepared under CEQA. In particular, the amendments to the CEQA Guidelines do not require or suggest specific methodologies for performing an assessment or thresholds of significance, and do not specify GHG reduction mitigation measures. Instead, the CEQA Guidelines amendments continue to rely on lead agencies to choose methodologies and make significance determinations based on substantial evidence, as discussed in further detail below (CNRA, 2009c). Consequently, no State agency has promulgated binding regulations for analyzing GHG emissions, determining their significance, or mitigating any significant effects in CEQA documents.

The discussion below provides a brief overview of CARB and Office of Planning and Research (OPR) documents and of the primary legislation that relates to climate change and that may affect the emissions associated with the Project. It begins with an overview of the primary regulatory acts that have driven GHG regulation in California, which underlie many of the GHG rules and regulations that have been developed.

1.4.1 Executive Order S-3-05 (State-Wide GHG Targets)

California Executive Order S-03-05 (June 1, 2005) establishes the goal of reducing GHG emissions to 2000 levels by 2010, to 1990 levels by 2020, and to 80% below 1990 levels by 2050. Although the 2020 target is the core of AB 32 and has effectively been incorporated into AB 32, the 2050 target remains the goal of the Executive Order only.²

1.4.2 Assembly Bill 32 (Statewide GHG Reductions)

The California Global Warming Solutions Act of 2006 (Assembly Bill (AB) 32) was signed into law in September 2006 after considerable study and expert testimony before the Legislature (State of California, 2006a). The law instructed CARB to develop and enforce regulations for the reporting and verification of state-wide GHG emissions. The bill directed CARB to set a state-wide GHG emission limit based on 1990 levels, to be achieved by 2020. The bill set a timeline for adopting a scoping plan for achieving GHG reductions in a technologically and economically feasible manner.

The heart of the bill is the requirement that state-wide GHG emissions be reduced to 1990 levels by 2020. Based on CARB's calculation of 1990 baseline emissions levels, California must reduce GHG emissions by approximately 28.5% below "business-as-usual" (BAU) predictions of year 2020 GHG emissions to achieve this goal.

In July 2011, CARB revised its "BAU" GHG emission estimate for 2020 in order to account for the recent economic downturn in its emission projections (CARB, 2011c). The estimate presented in the Scoping Plan (596 million metric tonnes CO₂e (MMT CO₂e) was based on pre-recession, 2007 data from the Integrated Energy Policy Report. CARB has updated the projected "BAU" 2020 GHG emissions to 545 MMT CO₂e.

AB 32 requires CARB to adopt rules and regulations in an open public process to achieve the maximum technologically feasible and cost-effective GHG reductions. Key AB 32 milestones for CARB's actions include the following:

- *June 30, 2007: Identification of discrete early action GHG emissions reduction measures.* On June 21, 2007, CARB satisfied this requirement by approving three early action measures (CARB, 2007b). These were later supplemented by adding six other discrete early action measures (CARB, 2007c).

² On November 6, 2013, the BAAQMD Board passed a resolution adopting the 2050 target of 80 percent below 1990 levels. Details of this resolution are described in the "Regional Provisions" section of this "Regulatory Setting" section.

- *January 1, 2008: Identification of the 1990 baseline GHG emissions level and approval of a state-wide limit equivalent to that level and adoption of reporting and verification requirements concerning GHG emissions.* On December 6, 2007, CARB approved a state-wide limit on GHG emissions levels for the year 2020 consistent with the determined 1990 baseline (CARB, 2007a).
- *January 1, 2009: Adoption of a scoping plan for achieving GHG emission reductions.* On December 11, 2008, CARB adopted *Climate Change Scoping Plan: A Framework for Change* (Scoping Plan), discussed in more detail below (CARB, 2008).
- *January 1, 2010: Adoption and enforcement of regulations to implement the “discrete” actions.* Several early action measures have been adopted and became effective on January 1, 2010 (CARB, 2007b; CARB, 2007c).
- *January 1, 2011: Adoption of GHG emissions limits and reduction measures by regulation.* On October 28, 2010, CARB released its proposed cap-and-trade regulations, which would cover sources of approximately 85% of California’s GHG emissions (CARB, 2010d). CARB’s Board ordered CARB’s Executive Director to prepare a final regulatory package for cap-and-trade on December 16, 2010 (CARB, 2010a).
- *January 1, 2012.* GHG emissions limits and reduction measures adopted in 2011 become enforceable.

1.3.1.1.17 Scoping Plan

As noted above, on December 11, 2008, CARB adopted the Scoping Plan to establish an overall framework for the measures that will be adopted to reduce California’s GHG emissions. CARB determined that achieving the 1990 emission level would require a reduction of GHG emissions of approximately 28.5% below what would otherwise occur in 2020 in the absence of new laws and regulations (referred to as “business as usual [BAU]”). The Scoping Plan evaluates opportunities for sector-specific reductions, integrates all CARB and CAT early actions and additional GHG reduction measures by both entities, identifies additional measures to be pursued as regulations, and outlines the role of a cap-and-trade program. Many of these measures and regulations have become effective on January 1, 2012. The key elements of the Scoping Plan (CARB, 2008) include:

- Expanding and strengthening existing energy efficiency programs as well as building and appliance standards;
- Achieving a state-wide renewables energy mix of 33%;

- Developing a California cap-and-trade program that links with other Western Climate Initiative partner programs to create a regional market system and caps sources contributing 85% of California's GHG emissions;
- Establishing targets for transportation-related GHG emissions for regions throughout California, and pursuing policies and incentives to achieve those targets;
- Adopting and implementing measures pursuant to existing state laws and policies, including California's clean car standards, goods movement measures, and the Low Carbon Fuel Standard; and
- Creating targeted fees, including a public goods charge on water use, fees on high global warming potential gases, and a fee to fund the administrative costs of the State of California's long-term commitment to AB 32 implementation.

In 2009, a coalition of environmental groups brought a challenge to the Scoping Plan alleging that it violated AB 32 and that the environmental review document (called a "Functional Equivalent Document") violated CEQA by failing to appropriately analyze alternatives to the proposed cap-and-trade program. On May 20, 2011, the San Francisco Superior Court entered a final judgment ordering that CARB take no further action with respect to cap-and-trade rulemaking until it complies with CEQA (*California Air Resources Board, et al., v. Association of Irrigated Residents, et al.*, 2011). CARB appealed the decision on May 23, 2011. The portions of the Scoping Plan that do not relate to cap and trade remained valid during the litigation. While the appeal was pending, CARB prepared a supplement to the Functional Equivalent Document that included the analysis that the trial court had determined was inadequate under CEQA. CARB certified the supplement to the Functional Equivalent document and readopted the Scoping Plan on August 24, 2011 (CARB, 2011b). On June 19, 2012, the California First District Court of Appeal upheld the Scoping Plan and affirmed CARB's approval of the Scoping Plan as in compliance with AB 32 (*Association of Irrigated Residents, et al., v. California Air Resources Board, et al.*, 2012).

In connection with the preparation of the supplement to the Functional Equivalent Document, CARB released revised estimates of the expected 2020 emissions reductions in consideration of the economic recession and the availability of updated information from development of measure-specific regulations. Incorporation of revised estimates in consideration of the economic recession reduced the projected 2020 emissions from 596 MMT CO₂e to 545 MMT CO₂e (CARB, 2011c). Under this scenario, achieving the 1990 emissions level would require a reduction of GHG emissions of 118 MMT CO₂e, or 21.7% (down from 28.5%), to achieve in 2020 emissions levels in the "BAU" condition.

The 2020 AB 32 baseline was also updated to account for measures incorporated into the inventory, including Pavley (vehicle model years 2009-2016) and the Renewables Portfolio Standard (RPS) (12% to 20%). Inclusion of these measures further reduced the 2020 baseline to 507 MMT CO₂e. As a result, based on both the economic recession and the availability of updated information from the development of measure-specific regulations, achieving the 1990 emission level would now require a reduction of GHG emissions of 80 MMT CO₂e or a reduction by approximately 16% (down from 28.5%) to achieve in 2020 emissions levels in the "BAU" or "No Action Taken" (NAT) condition (CARB, 2011b, CARB, 2011c).

On October 1, 2013, CARB released a discussion draft first update to the Scoping Plan. The discussion draft recalculates 1990 GHG emissions using the IPCC Fourth Assessment Report (AR4) released in 2007. The first draft update to the Scoping Plan states that, based on the AR4 global warming potentials, the 427 MMT CO₂e 1990 emissions level and the 2020 GHG emissions limit would be slightly higher than identified in the Scoping Plan, at 431 MMT CO₂e (CARB, 2013b). Based on (1) the revised estimates of expected 2020 emissions identified in the 2011 supplement to the Functional Equivalent Document, and (2) updated 1990 emissions levels identified in the draft first update to the Scoping Plan, achieving the 1990 emission level would require a reduction of 76 MMT CO₂e (down from 80 MMT CO₂e) or a reduction by approximately 15% (down from 28.5%) to achieve in 2020 emissions levels in the "BAU" or No Action Taken (NAT) condition.

The Scoping Plan identifies over 70 measures for reducing GHG emissions in sectors including transportation, electricity and natural gas, water, green buildings, industry, recycling and waste, and agriculture. Many of these measures incorporate laws, policies, and measures that are not solely driven by the AB 32 directive, including ship electrification (shorepower), high speed rail, RPS, and the Goods Movement Emission Reduction Plan. Regulatory development for other measures is ongoing. Of these measures, 44 were identified as Early Action Measures, which were adopted by CARB and made enforceable in 2010. These measures included regulations affecting landfills, motor vehicle fuels, refrigerant in cars, port operations, and many other sources.

Specific measures discussed in the Scoping Plan that are relevant to the Project include:

- Cap and Trade
- Renewable Portfolio Standard
- Low Carbon Fuel Standard
- Advanced Clean Cars
- Heavy Duty Truck Greenhouse Gas Regulation (SmartWay)

- Goods Movement
- Vessel Speed Reduction
- Freight Transport Efficiency
- Energy Efficiency and Co-Benefits Assessment for Large Industrial Sources
- Refinery Flare Recovery Process Improvements
- Removal of Methane Exemption from Existing Refinery Regulations

These are further discussed in following sections.

The Scoping Plan notes that local governments are “essential partners” in the effort to reduce GHG emissions, and that they have “broad influence and, in some cases, exclusive jurisdiction” over activities that contribute to GHG emissions. The Scoping Plan encourages local governments to adopt goals for reducing municipal GHG emissions and move toward adoption of a goal for reducing community emissions. These targets should parallel the State’s commitment to reduce GHG emissions by approximately 15% of current levels by 2020. The Scoping Plan also observes that “[l]ocal governments have the ability to directly influence both the siting and design of new residential and commercial developments in a way that reduces GHGs associated with vehicle travel, as well as energy, water, and waste” (CARB, 2008) and that “[i]ncreasing low-carbon travel choices (public transit, carpooling, walking and biking) combined with land use patterns and infrastructure that support these low-carbon modes of travel, can decrease average vehicle trip lengths by bringing more people closer to more destinations.” (CARB, 2008) It also notes that regional targets would be set and achieved on a regional basis through the Senate Bill (SB) 375 implementation process, which “maintains regions’ flexibility.” SB 375 is discussed below.

1.3.1.1.18 *Energy and Co-Benefits Assessment of Large Industrial Facilities*

In May 2011, CARB adopted the Regulation for Energy Efficiency and Co-Benefits Assessment of Large Industrial Facilities (CCR Title 17, Subchapter 10, Article 4, Subarticle 9). Stationary sources that emitted greater than 0.5 MMT CO₂e in 2009 and transportation fuel refineries and cement plants that emitted greater than 0.25 MMT CO₂e in 2009 are subject to this regulation. The regulation required these facilities to conduct a one-time assessment of the facility’s fuel and energy consumption and emissions of GHGs, criteria pollutants, and toxic air contaminants. As part of the assessment, facilities were required to identify potential energy efficiency improvement projects for equipment, processes, or systems the cumulatively account for at least 95% of the facility’s total GHG emissions. Assessment reports were due to CARB by December 15, 2011 (CARB, 2013f). The Chevron Facility is subject to this regulation (CARB, 2013d) and submitted the assessment report in accordance with the requirements of the regulation. On June 6, 2013, CARB published the Refinery Sector Public Report

summarizing the information received from the assessment reports for all refinery facilities in California (CARB, 2013c). In the report, a total of 76 potential energy efficiency improvement projects were identified for the Facility. These efficiency measures targeted boilers, electrical equipment, engines, and thermal equipment. Of those 76 measures, Chevron has completed or has started implementing 57 measures. Two of the projects were completed in 1992 and 1995, while the remaining projects were implemented between 2006 and 2011. Ten measures have been identified to be scheduled for the future and 9 projects are currently under investigation. In total, GHG emission reductions are estimated to range between 322,300 – 608,600 MT CO₂e, reflecting an increase in energy efficiency at the facility. CARB intends to prepare a final report with its conclusions and recommendations, based on the sector reports, in 2013.³

1.3.1.1.19 *California Mandatory Reporting Rule*

CARB adopted the California Mandatory Reporting Rule in December 2007 (CCR Title 17, Subchapter 10, Article 2). In December 2010, CARB adopted proposed revisions to support a California GHG cap-and-trade program and to harmonize with the Federal Rule. The revised rule, in effect starting January 1, 2012, eliminates many of the differences between the federal and California rules, though some remain. Additional modifications and clarifications were made to the rule in 2012 rulemaking and took effect starting January 1, 2013.

The California Mandatory Reporting Rule requires the reporting of GHG emissions from essentially the same source categories specified in the EPA Mandatory Reporting Rule, but with some differences. Most of the differences in the rules are related to ensuring that all sources subject to the California cap-and-trade regulations will also be subject to the California rule, and that GHG emissions reporting for those sources will meet the requirements of the cap-and-trade program. Additionally, California requires that emission reports be verified by a third party, and that sources emitting less than the federal reporting threshold but more than the California reporting threshold are subject to abbreviated reporting requirements.

1.3.1.1.20 *Cap-and-Trade Program*

The California Global Warming Solutions Act of 2006 (AB 32) allowed, but did not require, CARB to include among the mechanisms intended to reduce GHG emissions a “system of market-based declining annual aggregate emission limits.” The legislation required CARB to develop a Scoping Plan to describe the various mechanisms that would be used. In turn, the Scoping Plan, approved by CARB on December 11, 2008, directed CARB staff to develop, among other

³ The CARB report has not been issued as of the publication date of this report.

programs, a cap-and-trade mechanism that would apply a declining aggregate cap on GHG emissions⁴ and provide a flexible compliance system using tradable instruments.

On October 20, 2011, CARB adopted the final cap-and-trade regulation (CCR Title 17, Subchapter 10, Article 5). The program started on January 1, 2012, and will proceed in “compliance phases,” the first of which began on January 1, 2013. In the first phase, the program will apply to electric utilities, importers of electricity, and specified industries, including refineries. Approximately 350 electric utilities and approximately 600 industrial facilities were included in the initial phase of the program. In 2015, importers and distributors of fossil fuels will be added to the program in the second phase. The program will impose a “cap” on the total GHG emissions from covered entities in the state, and the quantity of emissions allowed under the cap will decrease each year, ultimately reaching the goal of returning state-wide GHG emissions to 1990 levels by 2020. (The quantity of allowed emissions actually increases between 2014 and 2015, but that is to account for the addition of the fuel importers and distributors and additional electricity importers to the program; the net effect is to reduce overall GHG emissions.)

To encourage emission sources to emit less as the cap decreases, “allowances,” or permission to emit GHGs, will be made available in decreasing quantities. Allowances will be both freely allocated and auctioned off. The amount of freely given allowances will decrease over time, and the severity of the decrease will vary by industrial sector, with those thought to be less vulnerable to out-of-state competition receiving fewer allowances more quickly. Similarly, the amount of allowances available for purchase at auction will decrease. The intent is to make reducing GHG emissions more financially attractive as the number of available allowances decreases, making each allowance more costly.

In May 2012, CARB considered proposed amendments to the California GHG emissions cap-and-trade program to (1) add security to the market system and help staff implement the cap-and-trade program, and (2) link the California cap-and-trade program with that of the Canadian province Quebec. The first set of amendments proposed additional information-gathering requirements during registration for the cap-and-trade program, rules and intermediate deadlines for participation in the first auction in November 2012, and provisions for implementing the allowance and offset registry and market monitoring. These amendments were approved in June 2012 and became effective in September

⁴ The cap-and-trade regulation applies to the following GHGs: carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulfur hexafluoride (SF₆), and nitrogen trifluoride (NF₃).

2012. The second set of amendments allows acceptance of Quebec compliance instruments for compliance with California's cap-and-trade regulation, and establishes requirements for linked compliance instrument registries and auctions. In June 2012, the California legislature passed SB 1018, which prohibits CARB from adopting any linkage programs until the Governor has reviewed the program and made four specific findings with the advice of the Attorney General. In January 2013, CARB issued revised amendments and supplementary documentation for public review. On April 8, 2013, Governor Brown issued a letter to CARB making the required findings under SB 1018 (Brown, 2013). On May 10, 2013, CARB adopted final regulatory amendments to provide for linkage of the Quebec and California cap-and-trade programs (CARB, 2013a).

1.3.1.1.20.1 Co-Pollutant Benefits

Implementation of the cap-and-trade program will also reduce state-wide emissions of criteria and toxic air pollutants. Because GHG emissions are largely the result of fuel combustion, as the cap decreases and state-wide combustion decreases, criteria and toxic air pollutants associated with combustion will also decrease state-wide. CARB also evaluated the potential for localized impacts from short-term increases in construction and operational emissions at facilities modifying operations in response to cap-and-trade compliance obligations. CARB's analysis indicated that localized impacts are unlikely due to existing local and state air quality regulations; however, where there is potential for significant impact from a proposed project, it would be addressed by local permitting agencies and CEQA lead agencies through the permitting and CEQA processes in which mitigation measures are evaluated.

1.3.1.1.20.2 Refinery Efficiency Metrics

The refinery industry uses "efficiency metrics" to identify industry performance standards and evaluate the operational efficiency of refineries in terms of energy usage and associated greenhouse gas emissions. More recently, the CARB cap-and-trade regulation used efficiency metrics to determine the allowance allocation for a given refinery, where more efficient refineries are rewarded with more directly allocated allowances. Efficiency metrics are intended to allow an equitable comparison across refineries, normalizing for differences in crude feed, products, and associated processing energy intensity. Different definitions of efficiency metrics exist, including the "Simple Barrel" method, the Solomon Energy Intensity Index (EII) method, and the Complexity Weighted Barrel (CWB) method. The more sophisticated efficiency metrics allow comparison of refineries of differing complexity without automatically penalizing the more complex refineries that fundamentally require more energy input to create more processed and higher-value products (e.g., gasoline, distillates), as compared to less complex refineries (e.g., topping refineries) that fundamentally require less

energy input to create less processed and lower-value products (e.g., naphtha, asphalt). More detailed descriptions of the Simple Barrel, Solomon EII, and CWB methods are as follows:

- **Solomon EII Method.** The Solomon EII is a proprietary method developed by Solomon Associates that compares a refinery's actual energy usage to the "standard" energy usage of a refinery of similar size and configuration. Here, energy efficiency is used as a proxy for GHG emissions efficiency. The "standard" energy usage value is calculated by Solomon Associates based on information reported by refineries that account for approximately 85% of global refining capacity and 90% of California's refining capacity (CARB, 2011a). Established in 1980, the Solomon EII method is considered the industry standard for comparing energy efficiency across refineries, and is used by industry and government entities alike, including the Western States Petroleum Association (WSPA), EPA Energy Star, and CARB. CARB adopted the Solomon EII method for calculating allowances in the cap-and-trade regulation first compliance period (2013-2014) for all refineries with an EII value. Refineries without an EII value are typically smaller and simpler; for these refineries, the cap-and-trade regulation uses the Simple Barrel method, as described below, to calculate allowances.
- **CWB Method.** The CWB method was initially developed during an Emissions Allocation Study for the Western States Petroleum Association. CARB has adopted a CWB method for calculating allowances for all refineries in the cap-and-trade regulation second compliance period (2015-2017) and onward. The CWB method is directly based on GHG intensity rather than an energy intensity proxy. The CWB method evaluates the GHG efficiency of each refinery process (e.g., vacuum distillation, fluid catalytic cracking, alkylation) and determines the refinery's overall efficiency from the sum of these processes. In this way, the CWB method accounts for differences in GHG emissions due to differences in refinery configurations, inputs, and outputs. The CWB method is more transparent than the Solomon EII method in that it is not based on a proprietary index; the California Mandatory Reporting Rule requires refineries to report all input and output information needed to perform the cap-and-trade CWB evaluation.
- **Simple Barrel Method.** The Simple Barrel method evaluates refinery efficiency based on total GHG emissions per barrel of product produced. Here, "total barrels of product" includes all products the refinery produces (e.g., gasoline, diesel, jet fuel, residual fuel oil, asphalt), regardless of the energy intensity needed to produce more sophisticated and higher-value products. CARB adopted the Simple Barrel method for calculating allowances in the cap-and-trade regulation first compliance period (2013-2014) for all refineries without a Solomon EII value. The refinery's total GHG emissions are

obtained from reports required by the EPA and California Mandatory Reporting Rule, and the total barrels of product produced are obtained from information reported to the EPA and the California Energy Commission (CEC). While the Simple Barrel method is indeed simple and relatively transparent, CARB noted that the method may disadvantage more complex refineries that produce more complex and higher-value products when compared to simpler refineries that produce simpler and lower-value products (CARB, 2010b).

A related efficiency metric is one that evaluates refinery efficiency based on total GHG emissions per barrel of crude oil refined. A recent study (Karras, 2011) by Communities for a Better Environment (CBE) commissioned by the Union of Concerned Scientists reported that California refineries on average emit 19 to 33% more GHGs per barrel of crude oil refined than refineries in any other major U.S. refining region. Proponents of this efficiency metric argue that California's greater GHG emissions can be attributed to California refineries processing denser crude of higher sulfur content, which require more energy input per barrel in order to refine into desirable products (Karras, 2010; Karras, 2011). The study notes that the declining availability of "cleaner" California and Alaska crude oils has resulted in California refineries importing "lower quality" foreign crude. Similar to the Simple Barrel method, this method disadvantages more complex refineries as compared to simpler refineries.

1.4.3 Regulation of Energy-Related Sources

1.3.1.1.21 *Renewables Portfolio Standard (SB 1078, SB 107, and SB X1-2)*

Established in 2002 under SB 1078 (State of California, 2002b), and accelerated in 2006 under SB 107 (State of California, 2006b) and again in 2011 under SB X1-2 (State of California, 2011), California's RPS requires retail sellers of electric services to increase procurement from eligible renewable energy resources to 33% of total retail sales by 2020. The 33-percent standard is consistent with the RPS goal established in the Scoping Plan (CARB, 2008). As interim measures, RPS requires 20% of retail sales to be sourced from renewable energy by 2013, and 25% by 2016. Initially, the RPS provisions applied to investor-owned utilities, community choice aggregators, and electric service providers. Senate Bill (SB) X1-2 added, for the first time, publicly owned utilities to the entities subject to RPS (State of California, 2011). The expected growth in RPS to meet the standards in effect in 2008 is not reflected in the "BAU" calculation in the AB 32 Scoping Plan, discussed above. In other words, the Scoping Plan's BAU 2020 does not take credit for implementation of RPS that occurred after its adoption (CARB, 2008).

1.3.1.1.22 *GHG Emissions Standard for Baseload Generation (SB 1368)*

SB 1368 (September 29, 2006) prohibits any retail seller of electricity in California from entering into a long-term financial commitment for baseload

generation if the GHG emissions are higher than those from a combined-cycle natural gas power plant (State of California, 2006b). This performance standard applies to electricity generated out-of-state as well as in the state, and to publicly owned as well as investor-owned electric utilities.

1.4.4 Regulation of Mobile Sources

1.3.1.1.23 Senate Bill 375 (Land Use Planning)

SB 375 provides for a new planning process to coordinate land use planning, regional transportation plans, and funding priorities in order to help California meet the GHG reduction goals established in AB 32 (State of California, 2008). SB 375 will be implemented over the next several years. SB 375 requires Metropolitan Planning Organizations (MPOs) relevant to the project area (including the Association of Bay Area Governments [ABAG]) to incorporate a “sustainable communities strategy” (SCS) in their regional transportation plans (RTPs) that will achieve GHG emission reduction targets set by CARB, primarily by reducing vehicle miles traveled (VMT) from light-duty vehicles through development of more compact, complete, and efficient communities.

SB 375 also required CARB to appoint a Regional Targets Advisory Committee (RTAC) to recommend factors for CARB to consider and methodologies for it to use in setting GHG emission reduction targets (Regional Targets) for each region. On September 29, 2009, the RTAC released its recommendations to CARB, who, on September 23, 2010, adopted Regional Targets applying to the years 2020 and 2035 (CARB, 2010c). In 2011, CARB adopted Regional Targets of 7% for 2020 and 15% for 2035 for the area under ABAG’s jurisdiction, which includes the Chevron Refinery. On July 18, 2013, the Metropolitan Transportation Commission and ABAG approved the final Plan Bay Area, which includes the Bay Area region’s first SCS as well as a new 2040 RTP and establishes the strategies for meeting the Bay Area’s Regional Targets (MTC, 2013).

The SCS is relevant to the Project only in that the Project is an employer. The SCS for the San Francisco Bay Area is discussed in the “Regional Provisions” section below.

1.3.1.1.24 Mobile Source Reductions (Pavley) (AB 1493)

AB 1493 required CARB to adopt regulations by January 1, 2005, to reduce GHG emissions from non-commercial passenger vehicles and light-duty trucks of model years 2009 through 2016 (State of California, 2002a). The bill required the California Climate Action Registry (CCAR) to develop and adopt protocols for the reporting and certification of GHG emissions reductions from mobile sources for use by CARB in granting emission reduction credits. The bill authorizes CARB to grant emission reduction credits for reductions of GHG emissions prior to the

date of the enforcement of regulations, using model year 2000 as the baseline for reduction.

In 2004, CARB applied to the EPA for a waiver under the federal Clean Air Act to authorize implementation of these regulations. The waiver request was formally denied by the EPA in December 2007 after California filed suit to prompt federal action. In January 2008, the State Attorney General filed a new lawsuit against the EPA for denying California's request for a waiver to regulate and limit GHG emissions from these vehicles. In January 2009, President Obama issued a directive to the EPA to reconsider California's request for a waiver. On June 30, 2009, the EPA granted the waiver to California for its GHG emission standards for motor vehicles. As part of this waiver, the EPA specified the following provision: CARB may not hold a manufacturer liable or responsible for any non-compliance caused by emission debits generated by a manufacturer for the 2009 model year. CARB has adopted a new approach to passenger vehicles – cars and light trucks – by combining the control of smog-causing pollutants and GHG emissions into a single coordinated package of standards. The new approach also includes efforts to support and accelerate the numbers of plug-in hybrids and zero-emission vehicles in California. These standards will apply to all passenger and light-duty trucks used by employees of and deliveries to the Project.

1.3.1.1.25 *Low Carbon Fuel Standard*

Executive Order S-01-07 (January 18, 2007) requires a 10% or greater reduction in the average fuel carbon intensity for transportation fuels in California regulated by CARB. CARB identified the Low Carbon Fuel Standard (LCFS) as a Discrete Early Action item under AB 32, and the final resolution (09-31) was issued on April 23, 2009. In 2009, CARB approved for adoption the LCFS regulation, which became fully effective in April 2010 and is codified in Title 17, California Code of Regulations, Sections 95480-95490. The LCFS will reduce GHG emissions by reducing the carbon intensity of transportation fuels used in California by at least 10% by 2020. Carbon intensity (CI) is a measure of the GHG emissions associated with the various production, distribution, and use steps in the "lifecycle" of a transportation fuel. The LCFS applies to fuel producers, importers, and distributors, including refineries like the Chevron Facility. To comply with the LCFS, refineries could consider measures to reduce GHG impacts along the full "lifecycle" of the transportation fuel, for example choosing to purchase crude oils and feeds of lower carbon content, improving the energy efficiency of refinery processes and equipment, and/or producing fuels of lower carbon content, such as ethanol-blended gasoline products. A recent study reported that in response to increased worldwide demand and oil prices, the number of types of crude oils being traded worldwide is growing, with the current 160 crude oil types varying widely in terms of geographic source, carbon

content, and energy intensity associated with extraction and processing (Gordeon, 2012).

On December 29, 2011, the U.S. District Court for the Eastern District of California issued several rulings in the federal lawsuits challenging the LCFS. Opponents argued that the LCFS violates the Supremacy Clause (US Constitution, Article VI, Clause 2)⁵ and Commerce Clause (US Constitution, Article 1, Section 8, Clause 3)⁶ of the U.S. Constitution by discriminating against fuel produced out-of-state. One of the district court's rulings preliminarily enjoined CARB from enforcing the regulation. In January 2012, CARB appealed that decision to the Ninth Circuit Court of Appeals (Ninth Circuit), and then moved to stay the injunction pending resolution of the appeal. On April 23, 2012, the Ninth Circuit granted CARB's motion for a stay of the injunction while it continued to consider CARB's appeal of the lower court's decision. On September 18, 2013, the Ninth Circuit issued its decision affirming the district court's conclusion that LCFS ethanol and initial crude-oil provisions are not facially discriminatory, but remanded to the district court to determine whether the LCFS ethanol provisions are discriminatory in purpose and effect. Additionally, the Ninth Circuit remanded to the district court with instructions to vacate the preliminary injunction against CARB's enforcement of the regulation (*Rocky Mountain Farmers Union v. CARB*, 2013).

CARB staff is developing proposed amendments for consideration by the CARB Board.⁷ Amendments under consideration specifically concerning refineries include allowing individual refiners a one-time opportunity to "opt out" of using the California average to calculate LCFS credits or deficits and instead use a refinery-specific or hybrid approach, and accounting for lifecycle carbon intensity associated with low-energy refineries. Additional amendments under consideration include updating the Indirect Land Use Change (iLUC) values, allowing electricity credits for electric rail and electric forklifts, adding a provision to address cost containment, incorporating additional fuel pathways

⁵ The Supremacy Clause establishes the U.S. Constitution, federal statutes, and the U.S. Treaties as "the supreme law of the land," establishing that federal laws take precedence over state laws.

⁶ The Commerce Clause grants the federal government the authority "To regulate Commerce within foreign Nations, and among the several States and with the Indian Tribes." Case law has determined that pollution and hazardous materials can be considered "commerce" because they can be produced in one state but dispersed or transported to other states.

⁷ According to the CARB LCFS website (<http://www.arb.ca.gov/fuels/lcfs/regamend13/regamend13.htm>), these amendments were scheduled for consideration at the October 2013 Board hearing. As of the date of the publication of this DEIR, CARB has not taken action to finalize or implement these amendments.

for alternative fuels including biodiesel, and developing sustainability provisions for awarding carbon intensity credits (e.g., for biofuel facilities) (CARB, 2013g).

1.3.1.1.26 *Clean Cars*

In January 2012, CARB approved the Advanced Clean Cars Program, which established an emissions control program for cars and light-duty trucks (such as SUVs, pickup trucks, and minivans) of model years 2017-2025. When the program is fully implemented, new vehicles will emit 75% less smog-forming pollutants than the average new car sold today, and GHG emissions will be reduced by nearly 35%. The program also requires car manufacturers to offer for sale an increasing number of zero-emission vehicles (ZEVs) each year, including battery electric, fuel cell, and plug-in hybrid electric vehicles.

In December 2012, CARB adopted regulations allowing car manufacturers to comply with California's GHG emissions requirements for model years 2017-2025 through compliance with the EPA GHG requirements for those same model years (CARB, 2012).

1.3.1.1.27 *SmartWay Truck Efficiency Regulation*

The SmartWay Truck Efficiency Regulation, approved by CARB in December 2008, requires heavy-duty long-haul tractors and box-type trailers to be equipped with technologies that reduce GHG emissions by improving fuel economy. These technologies include fuel-efficient and rolling-resistant tires and devices to improve truck aerodynamics. To comply with the regulation, fleet operators must either use EPA SmartWay-certified tractors and trailers or retrofit their existing fleet with SmartWay-verified technologies. All tractors and trailers must comply with the regulation when operated on California highways, regardless of where the vehicle is registered (CCR Title 17, Sections 95300 to 95312).

1.3.1.1.28 *Regulation of Ships*

1.3.1.1.28.1 *CARB Measures to Reduce Emissions from Goods Movement Activities*

The Goods Movement Emission Reduction Program (CARB, 2013e) and the 2006 Emission Reduction Plan for Ports and Goods Movement (Plan) in California (CARB, 2006) establish measures that reduce emissions (NO_x, PM, and GHGs) from the main sources associated with port cargo handling activities, including ships, harbor craft, terminal equipment, trucks, and locomotives. These measures reduce emissions, including GHG emissions, by requiring cleaner technologies and upgrades, low-carbon fuels, and/or programs that reduce fuel consumption through reduction of vehicle use or vehicle miles traveled. The Goods Movement Emission Reduction Program is a partnership among CARB, local air districts, and local seaports to reduce emissions and health risks from

freight movement. This program does not apply to oil loading and unloading that occurs via pipeline.

In addition, the California Environmental Protection Agency (Cal/EPA) (CARB's parent agency) has partnered with the California Business, Transportation and Housing Agency to prepare the Goods Movement Action Plan (GMAP) (CA DOT, 2007). The GMAP guides state-wide policy and planning for freight transport, trade corridors, and related air quality issues, as well as guides project selection for the allocation of funds under the Trade Corridors Improvement Fund (TCIF) Program, a state-wide fund used for infrastructure improvements along federally designated trade corridors of national significance (State of California, 2007). The GMAP was issued in two phases in 2005 and 2007. The Phase I report described the goods movement industry and its growth potential, the four priority regions and corridors (Los Angeles/Inland Empire, San Diego/Border, Central Valley, and Bay Area), the environmental and community impacts and preliminary mitigation approaches, and public safety and security issues. The Phase II report presents guidelines for integrating state-wide efforts to improve the goods movement system while mitigating environmental impacts (BTH and Cal/EPA, 2007).

1.3.1.1.28.2 CARB Vessel Speed Reduction for Ocean-Going Vessels

CARB is in the process of evaluating a state-wide vessel speed reduction program for ocean-going vessels. This program would require vessels within a certain distance of a port to slow to a specified speed. Reducing vessel speeds to an optimal value that minimizes fuel consumption on a per-distance basis translates into reduced GHG emissions (CARB, 2009b). Voluntary vessel speed reduction programs are already in place at several ports including the Port of Long Beach, the Port of Los Angeles, and the Port of San Diego.

1.3.1.1.29 Regulation of Trains

In response to the goals of AB 32, Measure T-6 "Freight Transport Efficiency" of CARB's Scoping Plan is intended to address GHG emissions from the freight transport sector by achieving at least a 3.5 MMT CO₂e reduction in GHG emissions from the sector by 2020. In May 2009, CARB held a workshop (CARB, 2009a) to outline objectives and research topics for further investigation; as of October 2013, however, CARB has not yet implemented any regulations or issued any formal regulatory documents for this measure.

1.4.5 CEQA Guidelines Amendments (SB 97)

The 2009 CEQA Guidelines amendments adopted pursuant to SB 97 state in Section 15064.4(a) that lead agencies should "make a good faith effort, to the extent possible on scientific and factual data, to describe, calculate or estimate"

GHG emissions. The CEQA Guidelines amendments note that an agency may identify emissions either by selecting a “model or methodology” to quantify the emissions or by relying on “qualitative analysis or other performance based standards.” (CNRA, 2009c) Section 15064.4(b) provides that the lead agency should consider the following when assessing the significance of impacts from GHG emissions on the environment:

- The extent a project may increase or reduce GHG emissions as compared to the environmental setting.
- Whether the project emissions exceed a threshold of significance that the lead agency determines applies to the project.
- The extent to which the project complies with regulations or requirements adopted to implement a state-wide, regional, or local plan for the reduction or mitigation of GHG emissions (CNRA, 2009c).

In addition, Section 15064.7(c) of the CEQA Guidelines amendments specifies “[w]hen adopting thresholds of significance, a lead agency may consider thresholds of significance previously adopted or recommended by other public agencies, or recommended by experts, provided the decision of the lead agency to adopt such thresholds is supported by substantial evidence” (CNRA, 2009c). Similarly, the revision to Appendix G, Environmental Checklist Form, which is often used as a basis for lead agencies' selection of significance thresholds, does not prescribe specific thresholds. Rather, Appendix G asks whether the project would:

1. Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment? or
2. Conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of GHGs?

This indicates that the determination of what is a significant effect on the environment should be left to the lead agency.

Accordingly, the CEQA Guidelines amendments do not prescribe specific methodologies for performing an assessment, do not establish specific thresholds of significance, and do not mandate specific mitigation measures. Rather, the CEQA Amendments emphasize the lead agency’s discretion to determine the appropriate methodologies and thresholds of significance consistent with the manner in which other impact areas are handled in CEQA (CNRA, 2009c).

The CEQA Guidelines amendments indicate that lead agencies should consider all feasible means, supported by substantial evidence and subject to monitoring and reporting, of mitigating the significant effects of GHG emissions. As pertinent to the Project, these potential mitigation measures, set forth in Section 15126.4(c), may include (1) measures in an existing plan or mitigation program for the reduction of GHG emissions that are required as part of the lead agency's decision; (2) reductions in GHG emissions resulting from a project through implementation of project design features; (3) off-site measures, including offsets, to mitigate a project's emissions; and (4) carbon sequestration measures (CNRA, 2009c).

Among other things, the CNRA noted in its Public Notice for these changes that impacts of GHG emissions should focus on the cumulative impact on climate change. The Public Notice states:

While the Proposed Amendments do not foreclose the possibility that a single project may result in greenhouse gas emissions with a direct impact on the environment, the evidence before [CNRA] indicates that in most cases, the impact will be cumulative. Therefore, the Proposed Amendments emphasize that the analysis of greenhouse gas emissions should center on whether a project's incremental contribution of greenhouse gas emissions is cumulatively considerable (CNRA, 2009b).

Thus the CEQA Guidelines amendments continue to make clear that the significance of GHG emissions is most appropriately considered on a cumulative level.

As described in the Final Statement of Reasoning (CNRA, 2009a) for the 2009 CEQA Guidelines amendments, the CEQA Guidelines specifically do not address lifecycle emission for two reasons. First, there are different interpretations of the meaning of "lifecycle" amongst lead agencies, which could lead to confusion on how to evaluate the contribution of lifecycle emissions to a project. Furthermore, requiring an analysis of lifecycle emissions may be inconsistent with CEQA, as the emissions may be outside the scope of the "indirect emissions" that are evaluated with a project. Lead agencies must evaluate substantial evidence to determine which emissions are indirect effects of a project and which emissions are outside the scope of CEQA.

1.4.6 Other State GHG Regulatory Activities

1.3.1.1.30 CARB Executive Order S-13-08

On November 14, 2008, Governor Arnold Schwarzenegger signed Executive Order S-13-08, which called on State agencies to develop a strategy for

identification of and preparation for expected climate change impacts in California. The resulting *2009 California Climate Adaptation Strategy* (CAS) report was developed by the CNRA in coordination with the CAT. The report presents the best available science relevant to climate impacts in California and proposes a set of recommendations for California decision-makers to assess vulnerability and promote resiliency in order to reduce California's vulnerability to climate change. Guidance regarding adaptation strategies is general in nature and emphasizes incorporation of strategies into existing planning policies and processes. An update to the CAS report is planned for release as a draft for public comment by the end of 2013 (State of California, 2013b).

In addition to requiring the CAT to create a Climate Adaptation Strategy, Executive Order S-13-08 ordered the creation of a comprehensive Sea Level Rise Assessment Report. The report, published in June 2012, indicates that the sea level along most of California's coast is expected to rise about 1 meter over the next century and is likely to increase the risk of damage in the form of flooding, coastal erosion, and wetland loss due to storm surges and high waves. The sea level increase is slightly higher than projected for global sea levels (NRC, 2012; ONPI, 2012).

Executive Order S-13-08 also called for the California Ocean Protection Council (OPC) to work with the other CAT State agencies to develop interim guidance for assessing the potential impacts of sea level rise due to climate change in California. In coordination with National Academy of Sciences (NAS) efforts, the OPC drafted interim guidance recommending that State agencies consider a range of sea level rise scenarios for the years 2050 and 2100 in order to assess project vulnerability, reduce expected risks, and increase resiliency to sea level rise. The draft resolution and interim guidance document is consistent with the Ocean Protection Act (Division 26.5, Public Resource Code Section 35615(a)(1)), which specifically directs the OPC to coordinate activities of State agencies to improve the effectiveness of State efforts to protect ocean resources (State of California, 2013c; CO-CAT, 2010).

1.3.1.1.31 Other Potentially Applicable Regulations or Policies

1.3.1.1.31.1 Assembly Bill 1613 (Waste Heat and Carbon Emissions Reduction Act)

AB 1613 directed the CEC, the CPUC, and CARB to implement the Waste Heat and Carbon Emissions Reduction Act. The Act is designed to encourage the development of new combined heat and power (CHP) systems in California with a generating capacity of not more than 20 megawatts. In June 2010, the CEC published modified final guidelines establishing technical criteria for eligibility of CHP systems for programs to be developed by the CPUC and publicly owned

utilities (CEC, 2010). Section 2843 of the Act provides that the CEC's guidelines require that CHP systems:

- Be designed to reduce waste energy;
- Have a minimum efficiency of 60%;
- Have NO_x emissions of no more than 0.07 pounds per megawatt-hour;
- Be sized to meet the eligible customer generation thermal load;
- Operate continuously in a manner that meets the expected thermal load and optimizes the efficient use of waste heat; and
- Be cost-effective, technologically feasible, and environmentally beneficial.

As directed by AB 1613, the CPUC also established (1) a standard tariff for the sale of electricity to electricity corporations for delivery to the electrical grid (State of California, 2013a); and (2) a "pay as you save" pilot program requiring electricity corporations to finance the installation of qualifying CHP systems by non-profit and government entities. A January 2011 decision by an administrative law judge determined that the pilot program will not be established due to lack of customer interest and difficulties in instituting a program that meets California Department of Corporations requirements (Decision 11-01-010 Before the Public Utilities Commission of the State of California, 2011).

1.3.1.1.31.2 Senate Bill X7 7 (Water Conservation Act of 2009)

The Water Conservation Act of 2009 sets an overall goal of reducing per-capita urban water use by 20% by December 31, 2020. The state is required to make incremental progress toward this goal by reducing per-capita water use by at least 10% by December 31, 2015. Reduction in water consumption directly reduces the energy necessary and the associated emissions to convey, treat, and distribute the water; it also reduces emissions from wastewater treatment.

The Department of Water Resources adopted a regulation on February 16, 2011 that sets forth criteria and methods for exclusion of industrial process water from the calculation of gross water use for purposes of urban water management planning. The regulation would apply to all urban retail water suppliers required to submit an Urban Water Management Plan, as set forth in the Water Code, Division 6, Part 2.6, Sections 10617 and 10620.

1.5 REGIONAL PROVISIONS

1.5.1 BAAQMD Regional Climate Protection Strategy Resolution

On November 6, 2013, the BAAQMD Board passed a resolution adopting a regional target of achieving 80% below 1990 levels of GHG emissions by 2050.

This reduction goal matches that of Executive Order S-3-05, described earlier. In addition, the resolution commits the BAAQMD to develop a regional climate protection strategy, including a Bay Area climate protection work program that will be included as an element of the BAAQMD's 2014 Clean Air Plan (BAAQMD, 2013).

1.5.2 ABAG/MTC Sustainable Communities Strategy (SB 375)

As discussed above, SB 375 is intended to help achieve AB 32's goals by coordinating land use and transportation planning, along with funding priorities. SB 375 requires each Metropolitan Planning Organization (MPO) in California to develop an Sustainable Communities Strategy (SCS) as part of its Regional Transportation Plan (RTP) that will achieve the GHG reduction targets required by AB 32. As described above, the Metropolitan Transportation Commission (MTC) and the Association of Bay Area Governments (ABAG) developed an SCS for the San Francisco Bay Area and incorporated it and a new RTP into a "Plan Bay Area." Plan Bay Area includes the Chevron Facility as a job center. Plan Bay Area developed under SB 375 included the Facility as an industrial source in its employment analysis. The Project will preserve this industrial source employment status, and is thus consistent with Plan Bay Area.

1.5.3 San Francisco Bay Plan

The San Francisco Bay Conservation and Development Commission (BCDC) was first established as a temporary state agency by the McAteer-Petris Act. BCDC was charged with preparing a plan for the long-term use of the bay and regulating development in and around the bay while the plan was being prepared. The San Francisco Bay Plan, which was completed in January 1969, includes policies on issues critical to the wise use of the bay ranging from ports and public access to design and transportation. The Bay Plan also contains maps of the entire bay that designate shoreline areas that should be reserved for water-related purposes like ports, industry, public recreation, airports, and wildlife refuges.

In August 1969, the McAteer-Petris Act was amended to make BCDC a permanent agency and to incorporate the policies of the Bay Plan into State law. In 1977, BCDC's authority was expanded to provide special protection of the Suisun Marsh. BCDC is also the federally designated State coastal management agency for the San Francisco Bay segment of the California coastal zone. This designation empowers BCDC to use the authority of the federal Coastal Zone Management Act to ensure that federal projects and activities are consistent with the policies of the Bay Plan and State law.

On October 6, 2011, BCDC approved amendments to the Bay Plan (BCDC, 2011a; BCDC, 2011b). The amendments address climate change by updating several sections of the Bay Plan (including Safety of Fills, Tidal Marshes and Tidal Flats, Shoreline Protection, and Public Access) and by adding a new climate change section with new findings and policies. There are five policy goals for the approved amendments:

1. Update language on sea level rise. This current policy language recommends that new development not be approved in low-lying areas that are in danger of flooding now or in the future unless the development is elevated above possible flood levels. The amended policies allow protection from flooding, encourage innovative means of dealing with flood danger, and make it clear that local governments will determine how best to deal with development proposals inland of BCDC's jurisdiction.
2. Encourage a variety of types of projects that have regional benefits. Proposed new development will continue to be evaluated by BCDC on a case-by-case basis to determine if the benefits of a project outweigh the risk from flooding and to ensure steps are taken to deal with the flooding danger.
3. Continue to protect the bay and other valuable natural resources within BCDC's jurisdiction.
4. Continue to protect existing tidal wetlands and, where appropriate, expand them. To accomplish this, resource protection and habitat enhancement in undeveloped low-lying areas will be encouraged, but development will not be absolutely prohibited in these areas.
5. Work with its regional partners, local governments, businesses, labor, environmentalists, investors, insurers, and the general public to develop a comprehensive regional strategy that deals with all the impacts of climate change.

APPENDIX 4.8 - SET

Greenhouse Gas Setting

APPENDIX 4.8-SET

GREENHOUSE GAS SETTING

There is international scientific consensus that anthropogenic emissions of greenhouse gases¹ have and will continue to contribute to changes in the global climate. Although there is uncertainty concerning the magnitude, rate, and ultimate effects of this change, it is generally accepted that climate change will result in a number of substantial adverse environmental impacts.

Climate change is the cumulative effect of all natural and anthropogenic sources of greenhouse gases on a global scale. The greenhouse gas emissions from an individual project, even a very large development project, would not individually generate sufficient greenhouse gas emissions to measurably influence global climate change (AEP, 2007; OPR, 2008). Consideration of a project's climate change impact, therefore, is essentially an analysis of a project's contribution to a cumulatively significant global impact through its emission of greenhouse gases. While it is possible to examine the quantity of greenhouse gases that would be emitted from individual project sources, it is not currently possible to link these greenhouse gases emitted from a specific source or location to particular global climate changes.

Although environmental impacts associated with climate change cannot be directly linked to individual development projects, the State of California recognizes the link between development activities and greenhouse gas emissions and is in the process of developing standards for assessment and, ultimately, regulation of the greenhouse gas emissions associated with land use. The State of California, through Assembly Bill (AB) 32 and Executive Order S-3-05, has set state-wide targets for the reduction of greenhouse gas emissions. The goal of AB 32 and Executive Order S-3-05 is to reduce future greenhouse gas emissions in a state that is expected to experience rapid growth in population and economic output. While the California Environmental Quality Act (CEQA) focuses on emissions associated with new development, other regulatory means will need to be implemented to address reductions in existing emissions.

¹ For the purposes of this analysis, the term "greenhouse gases" refers to carbon dioxide, methane, nitrous oxide, hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride, those gases regulated under California AB 32 and the Kyoto Protocol of the United Nations Framework Convention on Climate Change. Although the State of California also declared nitrogen trifluoride a greenhouse gas, there is no nitrogen trifluoride associated with this project. Therefore, nitrogen trifluoride will not be further considered.

1.1 GLOBAL SETTING

This section describes the status of global science on climate change and the scientific consensus regarding the role of anthropogenic greenhouse gas emissions in contributing to climate change and global warming. This section also describes global-scale estimates of greenhouse gas trends and projected effects on climate.

1.1.1 Global Climate Change

Global warming and global climate change are both terms that describe changes in the earth's climate. Global climate change is a broad term used to describe any worldwide, long-term change in the earth's climate. This change could be, for example, an increase or decrease in temperatures, the start or end of an ice age, or a shift in precipitation patterns. The term global warming is more specific than global climate change and refers to a general increase in temperatures across the earth. Though global warming is characterized by rising temperatures, it can cause other climatic changes, such as a shift in the frequency and intensity of rainfall or hurricanes. Global warming does not necessarily imply that all locations will be warmer. Some specific, unique locations may be cooler even though the world, on average, is warmer. All of these changes fit under the umbrella of global climate change.²

While global warming can be caused by natural processes, there is a general scientific consensus that most current global warming is the result of human activity on the planet (IPCC, 2007a). This human-made, or anthropogenic, warming is primarily caused by increased emissions of greenhouse gases that keep the earth's surface warm. This is called "the greenhouse effect." The greenhouse effect and the role that greenhouse gases play in it are described below.

1.1.2 The Greenhouse Effect

Greenhouses allow sunlight to enter, and then they capture some of the heat generated by the sunlight. Similarly, the earth's atmosphere acts like a greenhouse by retaining some of the heat that is generated by the sun. When solar radiation from the sun reaches the earth, much of it penetrates the atmosphere to ultimately reach the earth's surface; this solar radiation is absorbed by the earth's surface and then re-emitted as heat in the form of

² Other definitions of "greenhouse effect" and "global warming" can be found on Merriam-Webster online at <http://www.m-w.com/>. A definition for "climate change" can be found at <http://dictionary.reference.com>, which uses Webster's New Millennium™ Dictionary of English, Preview Edition (v 0.9.6). (Websites accessed March 1, 2013.)

infrared radiation.³ The warming potential of greenhouse gases does not come from the absorption of solar radiation but from the absorption of infrared radiation. When the infrared radiation is absorbed by the molecules of greenhouse gases, it is re-radiated in all directions. A portion of the infrared radiation is emitted back toward the surface of the earth, in effect “trapping” the heat in the atmosphere.⁴ This phenomenon is referred to as the “greenhouse effect.”

The earth’s greenhouse effect has existed far longer than humans have and has played a key role in the development of life. Concentrations of major greenhouse gases, such as carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), and water vapor, have been naturally present for millennia at relatively stable levels in the atmosphere, maintaining hospitable temperatures on the surface of the earth. Without these greenhouse gases, the earth’s temperature would be too cold for life to exist.

In the absence of major industrial human activity, natural processes have maintained atmospheric concentrations of greenhouse gases, and, therefore, global temperatures at constant levels over the last several centuries.⁵ As human industrial activity has increased, atmospheric concentrations of certain greenhouse gases have grown dramatically. Figure A4.8-SET-1 shows the increase in concentrations of CO₂ and CH₄ over the past 10,000 years, and particularly the dramatic increase since the Industrial Revolution. As the concentrations of greenhouse gases increase due to human activity, more infrared radiation is reflected back toward the earth, subsequently heating the surface of the earth to higher temperatures. This is the process that is described as human-induced global warming.

In 2007, the Intergovernmental Panel on Climate Change (IPCC) began releasing components of its Fourth Assessment Report (IPCC, 2007b), providing a comprehensive assessment of climate change science. The Fourth Assessment Report states that there is a scientific consensus that the global increases in greenhouse gases since 1750 are mainly due to human activities such as fossil fuel use, land use change (e.g., deforestation), and agriculture. In addition, the report states that it is likely that these changes in greenhouse gas concentrations

³ All light, be it visible, ultraviolet, or infrared, carries energy.

⁴ Infrared radiation is characterized by longer wavelengths than solar radiation. Greenhouse gases reflect radiation with longer wavelengths. As a result, instead of escaping back into space, greenhouse gases reflect much infrared radiation (i.e., heat) back to the earth.

⁵ Examples of natural processes include the addition of greenhouse gases to the atmosphere from respiration, fires, and decomposition of organic matter. The removal of greenhouse gases is mainly from plant and algae growth and absorption by the ocean.

Figure A4.8-SET-1
Chevron Refinery Modernization Project EIR
Increases in Carbon Dioxide and Methane Concentrations Over Time

have contributed to global warming. Confidence levels of claims in this report have increased since the release of the Third Assessment Report (IPCC, 2001) due to the large number of simulations run and the broad range of available climate models.

1.1.3 Greenhouse Gases and Greenhouse Gas Emission Sources

The term “greenhouse gases” includes gases that contribute to the natural greenhouse effect, such as CO₂, CH₄, N₂O, and water vapor, as well as gases that are only human-made and that are emitted through the use of modern industrial products, such as hydrofluorocarbons (HFCs), chlorinated fluorocarbons (CFCs), and sulfur hexafluoride (SF₆). These last three families of gases, while not naturally present in the atmosphere, have properties similar to the naturally occurring greenhouse gases that also cause them to trap infrared radiation when they are present in the atmosphere, thus making them greenhouse gases. These six gases comprise the major greenhouse gases that are recognized by the Kyoto Protocol (water is not included).⁶ A seventh gas, nitrogen trifluoride, was recently recognized by the California Air Resources Board (CARB) as a greenhouse gas.⁷ There are other greenhouse gases that are not recognized by the Kyoto Protocol or CARB, due to either the smaller role that they play in climate change or the uncertainties surrounding their effects. Atmospheric water vapor is not recognized by the Kyoto Protocol or CARB because there is not an obvious correlation between atmospheric water vapor concentrations and specific human activities. Atmospheric water vapor appears to act in a positive feedback manner; higher temperatures lead to higher atmospheric water vapor concentrations, which in turn cause more global warming (IPCC, 2001).

The effect each greenhouse gas has on global warming is a combination of the volume of its emissions and its global warming potential (GWP). GWP indicates, on a pound-for-pound basis, how much a gas will contribute to global warming relative to how much warming would be caused by the same mass of CO₂. CH₄ and N₂O are substantially more potent than CO₂, with GWPs of 21 and 310,⁸

⁶ The Kyoto Protocol sets legally binding targets and timetables for cutting the greenhouse gas emissions of industrialized countries. The U.S. has not approved the Kyoto Protocol.

⁷ Senate Bill 104, which directs CARB to regulate nitrogen trifluoride and possibly other gases found to be at least as harmful as CO₂ was signed into law by Governor Schwarzenegger in October 2009.

⁸ These GWPs are from the IPCC’s Second Assessment Report (IPCC, 1996). The more recent Fourth Assessment Report (IPCC, 2007b) includes different GWPs, but the GWPs from the Second Assessment Report will continue to be used by convention for reporting of 2013 emissions to CARB, as these values were used to set the Kyoto Protocol system and therefore are contained in this regulatory assessment. CARB has not yet decided when Fourth Assessment Report GWPs will be required for mandatory greenhouse gas reporting.

respectively. However, these natural greenhouse gases are nowhere near as potent as synthetic chemicals such as SF_6 and perfluoromethane, which have GWPs of 23,900 and 6,500, respectively compared to the GWP of 1 for CO_2 (CCAR, 2008).

Greenhouse gas emissions are typically measured in terms of mass of carbon dioxide equivalent (CO_2e). CO_2e is calculated as the product of the mass of a given greenhouse gas and its specific GWP.

The most important greenhouse gas in human-induced global warming is CO_2 . While many gases have much higher GWPs than the naturally occurring greenhouse gases, CO_2 is emitted in such vastly higher quantities that it accounts for 85% of the GWP of all greenhouse gases emitted by the United States (EPA, 2008). Fossil fuel combustion, especially for the generation of electricity and powering of motor vehicles, has led to substantial increases in CO_2 emissions and thus substantial increases in atmospheric CO_2 concentrations. In 2005, atmospheric CO_2 concentrations were about 379 parts per million (ppm), over 35% higher than the pre-industrial concentrations of about 280 ppm (IPCC, 2007a). In addition to the sheer increase in the volume of its emissions, CO_2 is a major factor in human-induced global warming because of its lifespan in the atmosphere of 50 to 200 years.

Concentrations of the second most prominent greenhouse gas, CH_4 , have also increased due to human activities such as rice production, degradation of waste in landfills, cattle farming, and natural gas mining. In 2005, atmospheric levels of CH_4 were more than double pre-industrial levels, up to 1,774 parts per billion (ppb) as compared to 715 ppb (IPCC, 2007a). CH_4 has a relatively short atmospheric lifespan of only 12 years but has a higher GWP than CO_2 .

N_2O concentrations increased from about 270 ppb in pre-industrial times to about 319 ppb by 2005 (IPCC, 2007a). Most of this increase can be attributed to agricultural practices (such as soil and manure management), as well as fossil-fuel combustion and the production of some acids. N_2O 's 120-year atmospheric lifespan increases its role in global warming.

Besides CO_2 , CH_4 , and N_2O , there are several gases and categories of gases that were not present in the atmosphere in pre-industrial times but now exist and contribute to warming. These include CFCs, used often as refrigerants, and their more stratospheric-ozone-friendly replacements, HFCs. Fully fluorinated species, such as SF_6 and perfluoromethane, are present in the atmosphere in relatively small concentrations but have extremely long life spans of 50,000 and 3,200 years each, making them potent greenhouse gases.

1.1.4 Current and Projected Climatic Impacts of Global Warming

A strong indication that anthropogenic global warming is currently taking place is the fact that the top seven warmest years since the 1890s occurred after 1997. Furthermore, a warming of about 0.2 degree Celsius (°C) per decade is projected by currently accepted models.

There is scientific consensus that global climate change will increase the frequency of heat extremes, heat waves, and heavy precipitation events. Other likely direct effects include an increase in the areas affected by drought and by floods, an increase in tropical cyclone activity, a rise in sea level, and recession of polar ice caps. The impacts of global warming have already been demonstrated by substantial ice loss in the Arctic (IPCC, 2007a, 2007c). Figure A4.8-SET-2 shows the rise of global temperatures, the global rise of sea level, and the loss of snow cover from 1850 to the present. Scenarios⁹ for 2100 modeled in the IPCC's Fourth Assessment Report include the following:

Temperature Increase by 2100

Low Emissions Scenario: 1.8°C (best estimate), with a range of 1.1°C to 2.9°C

High Emissions Scenario: 4.0°C (best estimate), with a range of 2.4°C to 6.4°C

Sea Level Rise by 2100

Low Emissions Scenario: 0.18 to 0.38 meters (range)

High Emissions Scenario: 0.26 to 0.59 meters (range)

It is important to recognize that the climatic conditions experienced by Richmond over the Chevron facility's designed lifetime are likely to be different from those observed worldwide over the past century. Consequently, it is useful to consider the implications of changing climatic conditions to the facility. Temperature increases and sea level rise in modeled scenarios in the IPCC Fourth Assessment Report may result in potential implications for the Chevron facility including the following:

⁹ Future greenhouse gas emissions are the product of very complex dynamic systems, determined by driving forces such as demographic development, socio-economic development, and technological change. Their future evolution is highly uncertain. Scenarios are alternative images of how the future might unfold and are an appropriate tool with which to analyze how driving forces may influence future emission outcomes and to assess the associated uncertainties. They assist in climate change analysis, including climate modeling and the assessment of impacts, adaptation, and mitigation. The possibility that any single emissions path will occur as described in scenarios is highly uncertain. More information on the IPCC's selection of scenarios is available at <http://www.ipcc.ch/ipccreports/sres/emission/index.htm>, accessed March 1, 2013.

01.29.2014 file path\U:\Chevron Renewal\ENVIRON Files\Report\Figures\Illustrator Files\Figure 4.3-21d-21e.ai
Source:IPCC2007a.

Figure A4.8–SET–2
Chevron Refinery Modernization Project EIR
Global Warming Trends and Associated Sea Level Rise and Snow Cover Decrease

- **Sea Level Rise:** Due to the facility's location, it is reasonable to consider that rising sea levels may affect the facility. It is not possible to reliably quantify these risks at this time; however, sea level rise impacts are discussed below and further reviewed in *Section 4.9, Hydrology and Water Quality* of this EIR.

Temperature: Rising temperatures could have a variety of impacts, including stress on sensitive populations (e.g., sick and elderly), additional burden on building systems (e.g., demand for air conditioning), and, indirectly, increasing emissions of greenhouse gases and criteria pollutants associated with energy generation. It is not possible to reliably quantify these risks at this time.

- **Precipitation:** Climate change is expected to alter seasonal and inter-annual patterns of precipitation. These changes continue to be one of the most uncertain aspects of future scenarios. For the Modernization Project, the most relevant direct impacts are likely to be changes in the timing and volume of stormwater runoff. It is not possible to reliably quantify the implications of these changes at this time.
- **Wildfire:** Changes in temperature and precipitation may combine to alter risks of wildfire. Changes in wildfire hazard are unlikely to affect the facility, however.
- **Water Supply Reliability:** Changes in temperature and precipitation may also influence seasonal and inter-annual availability of water supplies. Consequently, it is reasonable to consider that climate change may affect water supply reliability.

1.2 UNITED STATES SETTING

Total U.S. greenhouse gas emissions were approximately 6.6 billion metric tonnes (GT) CO₂e in 2009, 6.8 GT CO₂e in 2010, and 6.7 GT CO₂e in 2011 (EPA, 2013). Per capita emissions were approximately 21.6 metric tonnes (MT) CO₂e per person in the U.S. in 2010 (CAIT, 2013). While emissions did decrease from 2010 to 2011, U.S. emissions have increased by an annual average rate of 0.4% since 1990. Changes in fuel consumed to generate electricity—a decrease in coal consumption, an increase in natural gas consumption, and an increase in hydropower—coupled with a decrease in electricity demand due to a mild winter caused the decrease in total greenhouse gas emissions from 2010 to 2011.

Approximately 79% of the CO₂e emissions in the U.S. are comprised of CO₂ emissions from energy-related fossil fuel combustion (EPA, 2013).

According to the Emissions Database for Global Atmospheric Research (EDGAR), global greenhouse gas emission totaled approximately 50.1 GT CO₂e in 2010 (Joint Research Centre, European Commission, 2013). The top 10 emitting countries in 2010 were as follows:

China – 11.1 GT CO₂e
United States – 6.7 GT CO₂e¹⁰
India – 2.7 GT CO₂e
Russian Federation – 2.5 GT CO₂e
Indonesia – 1.9 GT CO₂e
Brazil – 1.6 GT CO₂e
Japan – 1.4 GT CO₂e
The Democratic Republic of Congo – 1.1 GT CO₂e
Germany – 0.98 GT CO₂e
Canada – 0.73 GT CO₂e

In 2011, CO₂e emissions from industrialized countries reporting their inventories to the United Nations Framework Convention on Climate Change (UNFCCC) were as follows (UNFCCC, 2013):

United States – 6.7 GT CO₂e
European Union (27 members) – 4.6 GT CO₂e
Russian Federation – 2.3 GT CO₂e
Japan – 1.3 GT CO₂e
Canada – 0.70 GT CO₂e

1.3 CALIFORNIA SETTING

In 2011, California emitted approximately 448 million metric tonnes (MMT) CO₂e, or about 6.7% of the total U.S. emissions where California is over 12% of the US population. Figure A4.8-SET-3 shows greenhouse gas emissions in California from 2000 to 2011.

In 2011, the largest source of greenhouse gas emissions in California (approximately 38%) was the transportation sector (CARB, 2013a). High GWP gases¹¹ accounted for approximately 3% of the CO₂e emissions in 2011 (CARB, 2013a). California's per-capita greenhouse gas emissions were 11.8 MT CO₂e per person in 2010 and 11.9 MT CO₂e per person in 2011 (CARB, 2013a). Figure A4.8-SET-4 shows California's per-capita greenhouse gas emissions compared to other states and the U.S. as a whole in 2010. Since 2000, California's per-capita greenhouse gas emissions have trended downward despite population growth, with the exception of a slight increase from 2010 to 2011. An overall decrease in gross greenhouse gas emissions since 2004 has also contributed to the decrease in per-capita greenhouse gas emissions (CARB, 2013a). Figure A4.8-SET-3 shows the downward trend in both overall emissions and per-capita emissions.

¹⁰ Slight difference between EPA value (6.8 GT CO₂e) and EDGAR value (6.7 GT CO₂e) may be due to differences in sources and methodology used by the two organizations.

¹¹ Such as HFCs and PFCs.

Source: CAIT 2013.

Figure A4.8-SET-4
Chevron Refinery Modernization Project EIR
U.S. GHG Emissions per Capita (2010)

In 2011, emissions from facilities required to report their greenhouse gas inventories to CARB under the California Mandatory Reporting Rule dropped for the third straight year from 133 MMT CO₂e in 2008 to 111 MMT CO₂e in 2011, coming in below the cap that CARB set for the first year of cap-and-trade emissions trading in 2013. The majority of emissions reductions were achieved in the electricity generation sector. CARB attributed the reductions in this sector to both increases in renewable power generation and decreases in state electricity consumption (CARB, 2013a). CARB forecasted 463 MMT CO₂e emissions in 2011; actual emissions were approximately 3% lower than forecasted. The forecast projects California's greenhouse gas emissions will reach approximately 507 MMT CO₂e by 2020 if no measures are taken to mitigate or decrease emissions (CARB, 2013b).

1.4 BAY AREA SETTING

The Bay Area Air Quality Management District (BAAQMD) published an updated inventory of greenhouse gas emissions in the San Francisco Bay Area Air Basin (Bay Area Basin) in February 2010 based on a 2007 inventory year. Total greenhouse gas emissions within the Bay Area Basin in 2007 were estimated as 95.8 MMT CO₂e. Fossil fuel consumption in the transportation sector and the industrial/commercial sector were the two largest sources of the Bay Area Basin's greenhouse gas emissions in 2007, each contributing about 36.4% of greenhouse gas emissions in the Bay Area Basin. The transportation and industrial/commercial sectors were followed by electricity/co-generation (15.9%), residential fuel usage (7.1%), off-road equipment (3.1%), and agriculture/farming (1.2%), as shown in Figure A4.8-SET-5 (BAAQMD, 2010).

To reduce future greenhouse gas emissions, the 2010 BAAQMD CEQA Guidelines, updated May 2011, (2010 BAAQMD CEQA Guidelines) suggest adopting a climate action plan that includes both a greenhouse gas emission inventory and a forecast of future emissions. In accordance with the 2010 BAAQMD CEQA Guidelines, the BAAQMD has created a forecast of greenhouse gas emissions through 2020 by applying sector-specific growth factors to the baseline year emissions (BAAQMD, 2011b). The BAAQMD greenhouse gas Plan Level Guidance document identifies specific growth metrics and data sources for the various sectors including residential, commercial, industrial, transportation, waste, water treatment, and agriculture (BAAQMD, 2011a). The BAAQMD projects that greenhouse gas emissions will increase by approximately 1.4% per year if current trends continue without mitigation (BAAQMD, 2010).

 2007 San Francisco Bay Area GHG Emissions by Sector

1.5 LOCAL SETTING

The City of Richmond prepared its first greenhouse gas inventory in February 2009 for an inventory year of 2005, in conjunction with Local Governments for Sustainability. The 2005 inventory¹² quantifies greenhouse gas emissions from municipal government operations as well as from the community within Richmond's city limits. Total greenhouse gas emissions were estimated as 5.8 MMT CO₂e, with municipal sources contributing less than 0.2% of the emissions. The Chevron facility contributed 60% of emissions in the commercial/industrial sector (City of Richmond and ICLEI, 2009). The rest of the emissions were attributed to other Richmond sources. These sources are commercial/industrial (70%), transportation (22%), residential (5%), and waste generation (2%) and landfill (1%). Figure A4.8-SET-6 shows the percentage of greenhouse gas emissions from the Chevron facility and the percentage of greenhouse gas emissions from other Richmond sources, broken down by sector. Figures A4.8-SET-7 and A4.8-SET-8 show the breakdown of greenhouse gas emissions by sector for Oakland and Contra Costa County, respectively. Oakland is shown here for comparison purposes since it is similarly situated with areas of heavy industry. And similar to Richmond, large sources of greenhouse gas emissions are outside the control of the City of Oakland.

1.6 CLIMATE CHANGE EFFECTS

The California Natural Resources Agency (CNRA) (CNRA, 2009a, 2009b) prepared a document that discusses the impacts of climate change upon California, as well as California's climate adaptation strategy. A first-year progress report was subsequently published 1 year after release of the original document (CNRA, 2010). In December 2013, CNRA released a draft update to the 2009 Climate Adaptation Strategy for public comment (CNRA, 2013). This update discusses nine broad areas that will be affected by climate change, developed seven strategies to help safeguard California, and summarized efforts to date. The document's goal is to protect California by reduce climate risks by helping inform decision makers. The categories below are topics emphasized in the November 2008 Executive Order (S-13-08), which called on State agencies to develop California's first strategy to identify and prepare for these expected climate impacts.

¹² Though the inventory was prepared in 2009, a baseline year of 2005 was chosen due to data availability and the decision to prepare a baseline inventory for the same year as other Bay Area cities.

Most Recent Reported Richmond GHG Inventory

(Chevron and Other Richmond Emission Estimates Combined):

2.3 million metric tons CO₂e (Other Richmond Sources)

3.5 million metric tons CO₂e (Chevron)

5.8 million metric tons CO₂e (total)

Other Richmond Emissions:

2.3 million metric tons CO₂e

Source: City of Oakland 2011.

NOTE: This figure depicts GHG emissions over which the City Government has a relatively high degree of influence. These sources include emissions occurring within Oakland's boundaries, as well as external emissions from citywide electricity consumption and waste sent to landfill. This does not include port operations, transportation on highways, air travel on flights departing from Oakland, or upstream lifecycle GHG emissions associated with material consumption. A full list of Oakland GHG emissions by source can be found in the Draft Appendix to the City of Oakland Energy and Climate Action Plan (March 1, 2011).

Contra Costa County GHG Emissions (2005)

1.6.1 Changing Temperatures

The CNRA described new projections by Massachusetts Institute of Technology modelers predicting a median probability of surface warming of 5.2°C by the year 2100, which is much higher than previous modeling completed in 2003 (Chandler, 2009). Researchers modeled temperature changes specifically related to California (Moser et al., 2008). The model predicted greater temperature increases in summer than in winter and larger increases inland compared to the coast.

1.6.2 Tipping Elements

The CNRA emphasized “tipping elements,” which bring about “abrupt changes that could push natural systems past thresholds beyond which they could not recover.” According to the CNRA, there are five main events (see Table A4.8-SET-1) that could bring about abrupt environmental changes. Each of these five has a particular tipping temperature at which the event is likely to occur. The consequence of crossing each threshold could cause a 7- to 12-meter rise in sea level over the course of several centuries.

TABLE A4.8-SET-1 TIPPING ELEMENTS THAT COULD TRIGGER ABRUPT ENVIRONMENTAL CHANGES

Additional Warming (°F)	Environmental Change	Length of Time for Change to Complete
1-3	Rapid Arctic sea ice melt	10 years
2-4	Irreversible melting of the Greenland Ice Sheet	300 years or more
5-9	Irreversible melting of the West Antarctic Ice Sheet	300 years or more
5-7	Amazon forest die-back	None given
6-11	Intensification of El Niño Southern Oscillation cycles	None given

Note: °F = degrees Fahrenheit

Source: CNRA, 2009a.

1.6.3 Extreme Natural Events

In addition, the CNRA listed extreme natural events are likely to occur, including higher nighttime temperatures and longer, more frequent heat waves overall; a 12–35% decrease in precipitation levels by mid- to late-21st century; increased evaporation and faster incidences of snowmelt that will increase drought conditions; and more precipitation in the form of rain as compared to snow that

will decrease water storage in California during the dry season and increase flood events during the wet season (Cayan et al., 2009).

1.6.4 Precipitation Changes

The CNRA also stated that climate change will intensify California's "Mediterranean climate pattern," with the majority of annual precipitation occurring between November and March and drier conditions during the summer (Cayan et al., 2006). This will increase droughts and floods and will affect river systems. One of the ways to quantify potential impacts related to river systems was by calculating a rise in water temperature and its effects on fisheries resources (Crossin et al., 2008).

1.6.5 Sea Level Rise

The CNRA stated that sea level rise can cause damage to coastal communities and loss of land, which according to a study published by the University of California-Berkeley Department of Agricultural and Resource Economics, could reach tens of billions of dollars per year in direct costs and trillions of dollars of assets in collateral risk (Kahrl and Roland-Holst, 2008). Current calculations of sea level rise from 1900 to 2000 estimate approximately 7 inches along the California coast (Cayan et al., 2006). Further, up to 55 inches of sea level rise globally by the end of the 21st century is predicted under the "business as usual" model (Cayan et al., 2009).

1.6.6 Water Supply Issues

California Health and Safety Code Section 38501(a) recognizes that climate change "poses a serious threat to the economic well-being, public health, natural resources, and the environment of California," and notes that "the potential adverse impacts of [climate change] include...reduction in the quality and supply of water to the state from the Sierra snowpack." As most of the state, including the San Francisco Peninsula, depends on surface water supplies originating in the Sierra Nevada, this water supply reduction is a concern.

Most of the scientific models addressing climate change show that the primary effect on California's climate would be a reduced snow pack and a shift in stream-flow seasonality. A higher percentage of the winter precipitation in the mountains would likely fall as rain rather than as snow in some locations, reducing the overall snowpack. Further, as temperatures rise, snowmelt is expected to occur earlier in the year, resulting in peak runoff that would likely come a month or so earlier. The end result would be that the state may not have sufficient surface storage to capture the resulting early runoff, and so, absent construction of additional water storage projects, a portion of the current

supplies would be lost to the oceans, rather than be available for use in the state's water delivery systems.

1.6.7 Low Sea Ice Levels

The CNRA stated that substantial sea ice melting from Greenland and the West Antarctic Ice Sheet has the potential to further raise sea levels. The sea ice extent in the Western Nordic Seas (i.e., Greenland, Norway, and Iceland Seas) is at the lowest level observed in the last 800 years. The implication is that a substantial reduction in sea ice in the Arctic sea promotes alterations in atmospheric circulation and precipitation patterns that extend to the mid-latitudes (e.g., the California coast). Additionally, it was reported that the variations in sea ice extent are correlated with changes in sea surface temperatures and atmospheric and ocean heat transport from the North Atlantic (Fauria et al., 2009).

The West Antarctic Ice Sheet is a marine-based ice sheet with edges that flow into floating ice shelves. Both the main sheet and the surrounding shelves have been showing signs of shrinking and collapsing due to global warming. Researchers have tracked the fate of at least nine shelves that have receded or collapsed around the Antarctic Peninsula in the past 50 years (Doyle, 2009).

1.6.8 Ocean Chemistry

The CNRA also noted that an emerging effect from climate change may be acidification of the ocean. In turn, acidification will affect the ability of hard-shelled invertebrates to create their skeletal structures (Risien, 2009). The implications of this change are major losses to shellfish industries and shifts in food resources for ocean fisheries. The primary contributing factors were cited as the increasing level of CO₂ and weather pattern shifts. Increases in CO₂ in the atmosphere result in increased uptake of CO₂ by the oceans, which result in decreased pH (acidification). Weather pattern shifts change the amount of calcium carbonate being delivered by rivers from sources stored in rocks, which further exacerbates the ability of invertebrates to form calcified shells (Griffith et al., 2008).

One of the main contributing factors to CO₂, outside of human influences, is melting permafrost. When permafrost thaws, it releases carbon into soil or beneath lakes and releases CO₂ and methane into the atmosphere. Scientists are now estimating that there is more than twice the total amount of carbon stored in permafrost as there is in atmospheric CO₂, and that microbial decomposition of organic carbon in permafrost “could amount to roughly half [of the CO₂ emissions] resulting from global land-use change during this century” (Schuur et al., 2008; ScienceDaily, 2008).

1.6.9 Socio-Economic Issues

Global temperature increases may have significant negative impacts on ecosystems, natural resources, and human health. Ecosystem structure and biodiversity will be compromised by temperature increases and associated climatic and hydrological disturbances (IPCC, 2007b). The availability and quality of potable water resources may be compromised by increased salinization of ground water due to sea level rise, decreased supply in semi-arid and arid locations, and poorer water quality arising from increased water temperatures and more frequent floods and droughts (IPCC, 2008). These impacts on freshwater systems, in addition to the effects of increased drought and flood frequencies, can reduce crop productivity and food supply.

In addition to compromising food and water resources, climatic changes associated with global warming can affect human health and welfare through other means. Warmer temperatures can cause more ground-level ozone, a pollutant that causes eye irritation and respiratory problems. Ranges of infectious diseases will likely increase, and some areas will face greater incidences of illness and mortality associated with increased flooding and drought events.

In its April 2007 Working Group II Report, the IPCC provided an assessment of the “current scientific understanding of the impacts of climate change on natural, managed and human systems, the capacity of these systems to adapt and their vulnerability” (IPCC, 2007b). Here, the IPCC states that, although some people will gain and some will lose because of global climate change, the overall change will be one of social and economic losses.

California in particular is an area that could be negatively affected by global warming. Global warming could alter the seasonal pattern of snow accumulation and snowmelt that serve as primary sources for California’s drinking water and irrigation water supplies. The scientific community projects extensions in the periods of high forest fire risk. Climatic changes would also affect agriculture, a major California industry, which could result in economic losses. For example, the heat wave in July 2006 is estimated to have cost the California dairy industry in excess of \$1 billion (Environment News Service, 2006).

APPENDIX 4.10

Consistency Evaluation of Relevant General
Plan Goals, Policies, and Actions

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
I. ECONOMIC DEVELOPMENT ELEMENT		
1. Goal ED2: Quality Jobs and Revenue Create an attractive business environment that will support business recruitment, expansion and retention. Attract a variety of small and large firms, national and local establishments, and up-and-coming industries and employers across a variety of economic sectors. Offer a broad range of quality employment opportunities for current and future residents with varying degrees of experience, education and training.	This Goal addresses the City's role in creating an attractive business environment. While individual Project applicants have no jurisdiction in directly implementing such policies, the Modernization Project is consistent with this Goal. As described in <i>Section 4.12, Employment, Population, and Housing</i>, the Project would retain the existing workforce and result in 29 additional new permanent full-time employees, approximately 1,002 construction jobs, and additional weatherization and other employment opportunities through the Community Greenhouse Gas Reduction Program. As Richmond's largest existing employer, the Chevron Facility offers employment opportunities to a local labor pool with a variety of experience, education and training.	4.10 Land Use, Plans, and Policies 4.12 Employment, Population, and Housing
2. Goal ED3: An Educated and Skilled Work Force Develop a skilled and educated workforce to support existing businesses and emerging industries. Equip residents with the skills and education necessary to participate in local and regional economies across a variety of sectors, and be fully engaged in the workforce. Encourage existing employers to expand and new employers to move their operations into the City by providing a strong local labor pool.	This Goal addresses the City's role in developing a skilled and educated workforce. While individual Project applicants have no jurisdiction in directly implementing this Goal, the Modernization Project is consistent with this Goal. As described in <i>Section 4.12, Employment, Population, and Housing</i>, the Project would retain the existing workforce and result in additional jobs employing a local labor pool with a variety of experience, education and training.	4.10 Land Use, Plans, and Policies 4.12 Employment, Population, and Housing
3. Policy ED1.4: Air Quality Support regional policies and efforts that improve air quality to protect human and environmental health and minimize disproportionate impacts on sensitive population groups. Work with businesses and industry, residents and regulatory agencies to reduce the impact of direct, indirect and cumulative	The Project is consistent with this Policy. The Project supports regional policies and efforts that improve air quality to protect human and environmental health by incorporating objectives that reflect a commitment to decreasing harmful impacts from emissions and protecting the community from environmental hazards, including a commitment to no net increase in criteria air pollutants, greenhouse gas emissions, and public health risks from air pollution, replacement of the existing hydrogen production plant with a more energy	4.3 Air Quality 4.8 Greenhouse Gases 4.6 Energy

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
impacts of stationary and non-stationary sources of pollution such as industry, the Port, railroads, diesel trucks and busy roadways. Fully utilize Richmond's police power to regulate industrial and commercial emissions. Ensure that sensitive uses such as schools, childcare centers, parks and playgrounds, housing and community gathering places are protected from adverse impacts of emissions. Continue to work with stakeholders to reduce impacts associated with air quality on disadvantaged neighborhoods and continue to participate in regional planning efforts with nearby jurisdictions and the Bay Area Air Quality Management District (BAAQMD) to meet or exceed air quality standards. Support regional, state and federal efforts to enforce existing pollution control laws and strengthen regulations. See also: CN4; CN4.1; CN4.A; CN4.B; PR4.2; HW1.8; HW9.1; EC5.3; CF1.3.	efficient plant, and modernization and increased equipment reliability and integrity of the Facility by replacing older equipment with newer, cleaner, and inherently safer technology. These Project objectives are further described in <i>Sections 4.3 Air Quality, 4.6 Energy, and 4.8 Greenhouse Gases</i>. Throughout the environmental review process the City has actively worked with regulatory agencies such as BAAQMD and the County to ensure that the Project would protect air quality. The City has requested, and BAAQMD has agreed, to monitor Chevron's implementation of the Air Quality Project Design Features identified in this EIR, which would reduce emissions from Refinery Operations, construction, and shipping. Project Design Features that avoid or reduce environmental impacts are required to be implemented as mitigation measures, and implementation would be required as a condition of Project approval. For all Project Design Features except some tank domes, completion of Project Design Features would be required prior to commencing operation of the new hydrogen plant or modified sulfur recovery unit. Also, as a condition of Project approval, Chevron would be required to annually file with the City a letter attesting that the Facility constraints identified in the air quality analysis in this EIR (average annual production of naphtha and residuum, and average annual shipping) continue to be valid and were not exceeded for the prior calendar year. Through construction and after installation of the Project the Facility would continue to comply with all Conditional Use Permit conditions and with the Facility's air quality permits. As described in <i>Section 4.3, Air Quality</i>, the Project was evaluated based on the public health, economic, demographic, educational, and other factors considered in the California Environmental Protection Agency (Cal/EPA) CalEnviroScreen tool to determine whether Project-related emissions would cause any disparate impacts in disadvantaged neighborhoods based on these criteria. As discussed in <i>Section 4.3, Air Quality</i>, the zip codes surrounding the Refinery rank in the higher percentage level of Cal/EPA's EnviroScreen Tool. In	

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	addition, the Project was evaluated in light of BAAQMD's study identifying communities that are disproportionately impacted from high concentrations of toxic air contaminants (i.e., "CARE" communities). The City of Richmond was designated as a CARE community, based on a combination of the toxic air contaminant emissions and concentrations data and locations of sensitive populations and income levels. As described in 4.3, <i>Air Quality</i>, the Modernization Project as proposed and mitigated would result in no net increase in criteria air pollutant emissions, and no net increase in public health risks from air pollution, including cancer risk and acute and chronic non-cancer health effects at sensitive receptor locations. Therefore, only de minimis health effects are anticipated. Because the Modernization Project would achieve its no net increase objective and would not increase health risks in an already impacted community, the Project is consistent with this Policy. In addition, after installation of the Project, emissions from the Facility would continue to be monitored through the Richmond Community Air Monitoring Program, which provides air monitor readings and educational tools to help the Richmond community understand air quality in their neighborhoods.	
4. Policy ED1.7: Richmond's Waterfront as a Community Amenity Continue to redevelop Richmond's waterfront as a publicly accessible amenity to attract new residential and commercial development and provide expanded recreational activities and open space. Waterfront sites with quality views can be leveraged for residential, commercial and recreational uses. The City's parks should also be maintained and enhanced to maximize their benefit	This Policy addresses the City's role in redeveloping Richmond's waterfront. While individual Project applicants have no jurisdiction in directly implementing such policies, the Modernization Project is consistent with this Policy. Because the Project would be constructed almost entirely on the Project site, away from the public shoreline of the Bay, and not within open space areas, the City's waterfront area would not be directly or indirectly affected. Additionally, the Project would not alter the San Francisco Bay Trail segments planned along the City's waterfront.	4.10 Land Use, Plans, and Policies

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
to the community and as an attraction for new businesses. See also: LU4.1; CN2; CN2.1; CN2.2; CN2.5		
5. Action ED1.G: Air Quality Monitoring and Reporting Program Work with the BAAQMD and other government agencies to establish and identify funding for a citywide air quality monitoring and reporting program. The air quality monitoring and reporting program would assess the cumulative impact of air pollution and toxins on human and environmental health and monitor exposure of sensitive uses such as schools, childcare centers, parks and playgrounds, housing and community gathering places. Collaborate with the County Health Services Department, the BAAQMD and state agencies to establish baseline exposures and document health effects associated with monitored baseline exposures and develop provisions to hold businesses and operations financially accountable for their impacts on the environment or community due to air pollution exceeding legal thresholds. See also: HW9.A; EC5.C; CN4.D	The Project is consistent with this Policy. This Policy relates to a citywide air quality monitoring and reporting program and establishment of a citywide air quality baseline. While individual Project applicants have no jurisdiction in directly implementing this Action, the Modernization Project is consistent with this Action. Specifically, as described in <i>Section 4.3, Air Quality</i>, and <i>4.8, Greenhouse Gases</i>, the City has requested and BAAQMD has agreed to monitor Chevron's implementation of the air quality and greenhouse gas project design features and mitigation measures identified in this EIR, implementation of which would be required as mitigation measures and as a condition of Project approval. Additionally, as described in <i>Section 4.3 Air Quality</i>, after installation of the Project, air quality in the vicinity of the Facility would continue to be monitored through the Richmond Community Air Monitoring Program, which provides air monitor readings and educational tools to help the Richmond community understand air quality in their neighborhoods.	4.3 Air Quality 4.8 Greenhouse Gases
6. Policy ED2.1: Local Employment Base Expand and diversify the local employment base to provide quality jobs for all Richmond residents, especially those that face barriers to employment	The Project is consistent with this Policy. As described in <i>Section 4.12, Employment, Population and Housing</i>, the Project would retain the existing workforce and result in new employment opportunities for local residents with	4.10 Land Use, Plans, and Policies 4.12 Employment,

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
such as youth, seniors, the formerly incarcerated, and residents with limited English proficiency. Richmond's economy should offer a broad range of quality employment opportunities for current and future residents with varying degrees of experience, education and training. By expanding and diversifying the local employment base, Richmond can establish itself as a major employment center in Contra Costa County and along the Interstate 80 and 580 corridors. Encourage businesses and industries that provide a safe work environment, living wages and benefits, and opportunities for skill development and advancement. Allow a range of industries and business types including a variety of small and large firms, established and up-and-coming industries, national and local establishments and employers across a variety of economic sectors including publicly owned and private port facilities. Support local businesses and entrepreneurs by providing a range of locations and flexible space opportunities including retail space along commercial corridors and office and light industrial space close to regional transportation infrastructure. Provide infrastructure improvements and incentives to support residents and businesses in establishing and expanding local enterprises in Richmond. Encourage local businesses to provide a range of quality jobs to residents, maximize and	a variety of experience, education and training. The manufacturing and industrial sector has historically been important to Richmond's economy. This is significant for Richmond residents as average wages for this sector are relatively high (\$64,000 in 2004), and this sector employs workers without higher levels of education. (See General Plan 2030, Economic Development Element, page 1.6.) The entire contractor construction workforce is expected to come from the construction labor pool available in the Bay Area, with many of the workers expected to come from within the City of Richmond and Contra Costa County. Additionally, the Community Greenhouse Gas Reduction Program would prioritize programs that employ local residents.	Population, and Housing

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
keep revenue in the City, and respond to community needs for key amenities and services. See also: HW6.1; LU3.2		
7. Policy ED2.2: Diverse and Expanded Tax Base Encourage a diverse and expanded tax base to protect the community from economic cycles. Draw from a broad set of revenues including sales and property taxes in order to remain fiscally healthy and provide the community with high-quality public services. Diverse land use policy, new and well-established employers who operate a variety of industries, and financially sound households will establish a solid tax base and help the City weather economic cycles.	This Goal addresses the City's role in encouraging a diverse and expanded tax base and in creating a diverse land use policy. While individual Project applicants have no jurisdiction in directly implementing such policies, the Modernization Project is consistent with this Policy. The Facility has been contributing to the City's tax base for over 100 years, and after the Project would continue to contribute revenue to the City's tax base and help the City weather economic cycles.	4.10 Land Use, Plans, and Policies
8. Policy ED2.4: Existing Employers Encourage established employers to remain and expand in Richmond in order to retain employers in key industries including green businesses, high-technology firms, food-related companies, port-related industries, medical services, manufacturing and distribution and retail/entertainment. Continuing to attract additional employers in sectors that are already established in Richmond will strengthen the local employment base. The City's central location, transit and freeway access are strengths that will be leveraged. These strengths particularly benefit companies that	This Policy addresses the City's role in encouraging established employers to remain in Richmond and attracting additional employers in established sectors. While individual Project applicants have no jurisdiction in directly implementing such policies, the Modernization Project is consistent with this Policy. The Facility is an established existing employer, providing approximately 1,200 jobs and an additional 400 contractor positions. The Project would provide Chevron more flexibility in its operations, thereby encouraging the Facility to remain in Richmond and continue to offer jobs across several sectors requiring a range of education and training, such as refining operations, research and development, and office administration. The Facility requires a mix of office and industrial space for manufacturing, research and development, and distribution.	4.10 Land Use, Plans, and Policies 4.12 Employment, Population, and Housing 4.8 Greenhouse Gases

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
require a mix of traditional office and industrial space for manufacturing, research and development, assembly, and distribution. The Port of Richmond with its bay access provides an advantage in attracting new firms.	With installation of the Project the Facility would continue to leverage the City's central location, transportation infrastructure, and water access through import and export of raw goods and products via ship over the Long Wharf as well as rail and truck. Additionally, the Community Greenhouse Gas Reduction Program proposed as part of the Project would generate jobs, including anticipated weatherization on existing residential and commercial structures, which would require some mix of traditional office space and industrial space for assembly and distribution. Thus the Project would contribute to retaining the Facility as an established employer.	
9. Policy ED2.6: Environmentally Progressive Businesses and Industries Encourage existing businesses and industries to become increasingly environmentally progressive and continue making positive contributions to the community. Encourage businesses and industries to hire locally and to demonstrate reasons for not hiring local employees. Seek reciprocity in the hiring of Richmond residents in Contra Costa County and other nearby jurisdictions with local hiring ordinances. Encourage businesses and industries to participate in civic life and play a positive role in the community. Together with regulatory agencies, actively work with local industries to ensure compliance with all applicable environmental regulations to limit pollution, decrease harmful impacts from emissions and protect the community from environmental hazards.	The Project is consistent with this Policy. The Project incorporates objectives that reflect a commitment to decreasing harmful impacts from emissions and to protecting the community from environmental hazards, including a commitment to no net increase in criteria air pollutants, greenhouse gas emissions, and public health risks from air pollution, replacement of the existing hydrogen production plant with a more energy efficient plant, and modernization and increased equipment reliability of the Facility by replacing older equipment with newer, cleaner, and inherently safer technology. The Project would implement environmentally progressive measures including electricity efficiency upgrades and fuel efficiency upgrades, as described in <i>Section 4.6, Energy</i>. The Project is also consistent with this Policy in that throughout the environmental review process the City has actively worked with regulatory agencies such as BAAQMD and the County to ensure compliance with all applicable environmental regulations. Through construction and after installation of the Project, the Facility would continue to comply with all Conditional Use Permit conditions and with the Facility's air quality permits. Additionally, as described in <i>Section 4.3, Air Quality</i>, after installation of the Project, air quality in the vicinity of the Facility would continue to be monitored through the Richmond Community Air Monitoring Program, which provides air	4.3 Air Quality 4.6 Energy 4.8 Greenhouse Gases 4.10 Land Use, Plans, and Policies 4.13 Public Safety

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
Promote and encourage new clean and green industries that provide well-paying jobs, revenue and other community and environmental benefits; support efforts to require existing industries to decrease harmful emissions and impacts; and promote a mix of uses and a range of activities on industrial land to create jobs and revenue while avoiding conflict between industrial and nonindustrial uses. See also: HW6.4; LU3.1; EC5.2	monitor readings and educational tools to help the Richmond community understand air quality in their neighborhoods. In addition, the proposed Community Greenhouse Gas Reduction Program is anticipated to create green jobs to be filled at least partially by local residents including in the weatherization of existing residential and commercial buildings, and would prioritize funding for programs that create local jobs and create community wealth. The Project could also implement the installation of a 2-MW solar cell facility as a mitigation menu option, as described in <i>Section 4.8, Greenhouse Gases</i>.	
10. Policy ED2.7: High Job Density Develop strategies to attract high-density employers and actively pursue employers that maximize the number of jobs located on a site. Consider using the number of “jobs added per acre” as an evaluative criterion for the review land use proposals.	The Project is consistent with this Policy because it increases the density of jobs located at the existing Facility. As of March 2013, the approximate workforce count (employees and contractors on a routine basis) at the Facility is 1,200 full-time employees and 400 contractors. (Chevron Data Transmittal #41, 2013) Therefore, the Facility currently provides 0.55 job per acre. The Project would retain the existing workforce and result in 29 additional new permanent full-time employees (Chevron Data Transmittal #5, 2014). With the additional new permanent jobs, the Facility would provide 0.56 job per acre.	4.10 Land Use, Plans, and Policies 4.12 Employment, Population, and Housing
11. Action ED2.F: Coordination with Major Employers Regularly meet with Richmond’s major employers to discuss opportunities for community development partnerships and joint planning efforts and facilitate ongoing communication among staff, elected officials and employers. Some of Richmond’s largest employers occupy large parcels of land and play vital roles in the economic well-being of the community. Ongoing	The Project is consistent with this Action. The Facility is a major employer that occupies a large parcel of land in the City of Richmond and that plays an important role in the economic well-being of the community. Throughout the environmental review process for the Project, the City, Chevron, and interested community groups have engaged in ongoing communication to ensure a productive working relationship, including several informational meetings before City Council and with members of the community. These communications have addressed technical topics to be included in the proposed Project EIR, the proposed Community Greenhouse Gas Reduction Program, and CEQA and BAAQMD guidelines. The Project would require	4.8 Greenhouse Gases 4.10 Land Use, Plans, and Policies 4.12 Employment, Population, and Housing

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
communication will ensure a positive working relationship among groups and signal commitment from the City to collaborate with its major employers on a variety of land use, programmatic or other economic development issues.	ongoing reporting and communication between the applicant and the City. See <i>Chapter 9, Mitigation Monitoring and Reporting Program</i> .	
12. Policy ED3.1: Public-Private Partnerships Encourage and support existing and potential employers to participate in local workforce development programs. Play a strong role in linking employers with educational institutions and service providers to train Richmond residents for well-paying jobs in their community.	The Project is consistent with this Policy. The Project proposal includes a Community Greenhouse Gas Reduction Program, which is anticipated to include Chevron funding for existing local workforce development programs. The Community Greenhouse Gas Reduction Program would also prioritize programs that create jobs for local Richmond residents, and is anticipated to include green jobs such as weatherization of existing residences and commercial properties.	4.10 Land Use, Plans, and Policies 4.12 Employment, Population, and Housing
13. Policy ED3.2: Workforce Training and Recruitment Support and enhance jobs-skills training and recruitment programs and services. Collaborate with educational institutions, employers, unions and the local workforce development programs to strengthen services for Richmond youth and adults. Support and enhance education, training and recruitment programs and services for local residents to increase job and employment opportunities and compete in the regional economy. See also: HW6.2	The Project is consistent with this Policy. The Project proposal includes a Community Greenhouse Gas Reduction Program, which would prioritize programs that create jobs for local Richmond residents, and is anticipated to include green jobs such as weatherization of existing residences and commercial properties. As described in <i>Section 4.12, Employment, Population, and Housing</i> , Chevron currently contributes to local training and job creation programs.	4.10 Land Use, Plans, and Policies 4.12 Employment, Population, and Housing
14. Policy ED 9.1: A Mix of Land Uses Promote a mix of uses to create a complete community in the San Pablo Peninsula area.	The Project is consistent with this Policy. As described in <i>Section 4.10, Land Use, Plans, and Policies</i> , because the Project would be constructed almost entirely on Project site, away from the public shoreline of the Bay, the shoreline	4.10 Land Use, Plans, and Policies 4.15 Parks and

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
Develop lodging and visitor-serving concessions (such as cafes, bike and kayak rental kiosks) to elevate the San Pablo Peninsula as a local and regional destination and complement its potential development as a resort and entertainment center. Residential uses should also be explored for the area to add to its 24-hour vitality and to capitalize on Bay views.	area and other public open space areas would not be directly or indirectly affected. The Project would not alter the San Francisco Bay Trail segments planned along the shoreline. For these reasons, the Project would not conflict with the promotion of mixed uses to create a complete community in the San Pablo Peninsula area.	Recreation
III. LAND USE ELEMENT		
15. GOAL LU3: Expanded Economic Opportunities Expand economic opportunities in existing commercial and industrial areas and develop new opportunities to diversify the local economy. Create an attractive and socially-responsible business environment that will support business recruitment, expansion and retention. Encourage innovative, high-growth and green business, and further support businesses and industries in providing a range of job and entrepreneurial opportunities while minimizing environmental and health impacts. In building a thriving local economy, develop a skilled and educated workforce that can strengthen existing businesses and emerging industries. Establish Richmond as a major employment center in Contra Costa County and along the Interstate 80 and 580 corridors by expanding and diversifying the local employment base.	The Project is consistent with this Goal. The Project expands economic opportunities in an existing industrial area by modernizing Facility equipment, providing the Facility more flexibility in meeting market demand while continuing to provide a diverse range of job opportunities to local and area residents. The Facility is one of Richmond's largest employers, employing a skilled workforce of approximately 1,600 workers (1,200 employees plus 400 contractors). The Project would allow the Facility to maintain its current job base as well as add 29 permanent jobs and up to 990 temporary jobs during the peak six-month period of construction. In addition, the proposed Community Greenhouse Gas Reduction Program is anticipated to create green jobs to be filled by local residents including in the weatherization of existing residential and commercial buildings. Finally, the proposed Community Greenhouse Gas Reduction Program would prioritize funding for programs that create local jobs and create community wealth. Thus the Project is consistent with this Policy in that would expand economic opportunities at the existing Facility. The Project would provide this economic expansion while minimizing environmental and health impacts. The Project includes a commitment to no net increase of public health risks from air pollution, and no net increase in	4.3 Air Quality 4.6 Energy 4.8 Greenhouse Gases 4.10 Land Use, Plans, and Policies

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
Capitalize on Richmond’s amenities and convenient location in order to attract new businesses to the Southern Shoreline, Hilltop, Downtown, the Port and surrounding industrial areas. Transform the Hilltop Area, the Southern Shoreline and the Richmond Parkway as mixed-use regional destinations and employment centers. Leverage Richmond’s rich cultural, historical and natural amenities to ignite a vibrant cultural-heritage and tourism industry.	criteria air pollutants and greenhouse gases above the Baseline level. As described in <i>Section 4.3, Air Quality</i>, the Project would achieve these objectives through a combination of Emission-Reduction Project Design Features, which would be required to be implemented as mitigation measures, including for example installation of new equipment such as tank domes to reduce volatile organic compound (VOC) emissions, and other specific, feasible mitigation measures to reduce emissions. In addition, through construction and after installation of the Project, the Facility would continue to comply with all Conditional Use Permit conditions and with the Facility's air quality permits, further ensuring that any environmental or health impacts would be minimized. With installation of the Project, the Facility would continue to leverage the City's transportation infrastructure and water access. The Project would be constructed almost entirely within the existing Facility and would not affect Richmond's cultural, historical, or natural amenities.	
16. GOAL LU4: Enhanced Environmental Quality Protect and preserve natural resources to nurture environmental and human health. Work with local and regional regulating bodies to protect water quality in creeks and bays, and to reduce or mitigate air, water and soil pollution and contamination. Encourages the sensitive integration of built and natural environments to develop a high-quality urban experience. See also: HW9; CN3; EC4.4	The Project is consistent with this Goal. The Project includes a commitment to no net increase in criteria air pollutants and greenhouse gases, and no net increase in public health risks from air pollution. As described in <i>Section 4.3, Air Quality</i>, and <i>4.4, Greenhouse Gases</i>, the Project would achieve these objectives through a combination of Emission-Reduction Project Design Features, including for example installation of new equipment such as tank domes to reduce VOC emissions, and specific, feasible mitigation measures to reduce emissions. Project Design Features that avoid or reduce environmental impacts are required to be implemented as mitigation measures. In addition, through construction and after installation of the Project, the Facility would continue to comply with all Conditional Use Permit conditions and with the Facility's air quality permits. The Project would avoid sensitive environmental land and features because the Project is located almost entirely on Facility property in areas that have been	4.3 Air Quality 4.4 Biological Resources 4.6 Energy 4.7 Geology, Soils, and Seismicity 4.8 Greenhouse Gas 4.9 Hydrology and Water Quality 4.10 Land Use, Plans, and Policies

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
17. GOAL LU5: Balanced and Compatible Uses Achieve a mix of land uses that is ecologically,	previously disturbed, and the areas where the Project would be constructed and operated do not include wetlands, marshlands, and creeks. As described in <i>Section 4.9, Hydrology and Water Quality</i>, the Facility is served by its own wastewater system and there would be no net increase in wastewater. The process wastewater streams at the Facility are treated by its wastewater treatment plant prior to discharge, and would continue to be required to comply with National Pollutant Discharge Elimination System (NPDES) discharge limitations after installation of the Project. Most of the construction and ground disturbance activities for the Project have already been completed, and significant new excavation activities would not be undertaken in areas of the Facility that are not already developed. Any leaching of contaminants that might occur from soil stockpiles would be conveyed to the Facility's wastewater treatment system through stormwater systems. Since construction of most of the Project would occur in the Refinery Process Area of the site, erosion impacts would not be anticipated. Water and soil quality would be protected during dismantling of the existing hydrogen plant. Steel and metal would be recycled, and non-recyclable materials properly disposed of at approved disposal sites. Applicable Storm Water Pollution Prevention Plan requirements would be implemented during dismantling activities. Excavation work would be minimized and include dust control measures. The Project is also consistent with this Policy in that throughout the environmental review process, the City has worked closely with regulatory agencies such as BAAQMD and Contra Costa County to ensure protection of water quality, and to avoid, reduce or mitigate air, water and soil pollution and contamination.	4.10 Land Use, Plans, and Policies

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
economically and socially equitable and sustainable. Encourages a mix of uses in major activity centers, community nodes and gateways, in neighborhood nodes and along key corridors as well as in some industrial areas. Using this pattern and range of land uses, activate focal areas of the City throughout the day and evening, and provide convenient access to goods, services and community amenities.	and operated almost entirely within the existing Facility.	
18. Policy LU3.7: Retention and Modernization of Heavy Industrial Uses Retain and support the modernization of Richmond’s existing heavy industrial uses and support their continued transition to cleaner and more energy-efficient operations in order to reduce impacts to human and environmental health. See also: LU 3.I	The Project is consistent with this Policy, as the objective of the Project is to modernize certain equipment, including the installation of Emission-Reduction Project Design Features, and support the Facility’s transition to less emitting and more energy efficient operations in order to reduce impacts to human and environmental health. Specifically, an objective of the Project is modernize, and increase equipment reliability and integrity of, the Facility by replacing older equipment with newer, cleaner, and inherently safer technology. The Project would achieve this objective by, for example, the installation of a more modern hydrogen plant, which would be more energy efficient, resulting in reduced fuel usage per hydrogen product, and subsequently less air pollutant emissions, compared to the existing plant, as described in <i>Section 4.3, Air Quality</i>. The Project would also include installation of low-NO_x burners on several furnaces and at the sulfur recovery units. The Project would also include new treatment of refinery fuel gas to remove sulfur emissions, as well as installation of tank domes to reduce fugitive VOC emissions, and upgrading of approximately 6,000 lighting fixtures in the process plant areas of the Facility with light emitting diode (LED) lighting. (See <i>Chapter 3, Project Description, Sections 3.3, and 4.3, Air Quality</i>, for further discussion.) Because the Project would allow the Facility to install more modern equipment, it is consistent with the Policy of retaining and modernizing an existing heavy	4.3 Air Quality 4.6 Energy 4.8 Greenhouse Gases 4.10 Land Use, Plans, and Policies

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	industrial use.	
19. Action LU3.H: Industrial Lands Retention and Consolidation Ensure that industrial uses are consolidated around rail and port facilities and work with existing industrial operators, economists and commercial brokers to remain informed about the future demand for industrial land.	The Project is consistent with this Action. The existing Facility is consolidated around rail facilities and the Long Wharf, and the Project would be constructed almost entirely within the Project site boundary.	4.10 Land Use, Plans, and Policies
20. Policy LU4.4: Toxic and Contaminated Sites Continue to work with the appropriate local, state, and federal agencies to promote the clean-up and reuse of contaminated sites to protect human and environmental health. Work with property owners and regional agencies to prevent, reduce or eliminate soil and water contamination from industrial operations, the Port and other activities that use, produce or dispose of hazardous or toxic substances. Implement appropriate mitigation measures and clean-up of sites that are known to contain toxic materials as a condition of reuse. Support the remediation and reuse of large, disturbed sites, such as the Winehaven complex at Point Molate and the Terminal 4 site at Point San Pablo, into mixed-use centers that provide the maximum benefit to the community without compromising the integrity of the surrounding natural areas. See also: CN6.1; ED1.3; HW9.2.	The Project is consistent with this Policy. The Project would protect human and environmental health by following BAAQMD and the California Occupational Safety and Health Administration (Cal/OSHA) and any other applicable federal, state, and local regulations for the proper closure of the existing hydrogen plant to ensure no hazardous or toxic substances are left behind. Any excavated soil would be tested for hydrocarbons and managed in conformance with the Facility's RQWCB-approved Soil Management Program for handling and disposition. Also as required, excavated soil that is contaminated would be managed in accordance with BAAQMD Regulation 8 (Organic Compounds), Rule 40 (Contaminated Soil). After the new hydrogen plant is constructed and fully operational, the existing hydrogen plant would be shut down, decommissioned, and dismantled, BAAQMD and Cal/OSHA would be notified as required and appropriate measures taken to ensure that all applicable regulatory requirements for asbestos abatement are met. In addition, building permits would be obtained as required from the City of Richmond. As discussed in <i>Section 4.9, Hydrology and Water Quality</i>, most of the ground disturbing activities for the Project are already completed. All remaining proposed excavation related to the Project would be conducted entirely within the Refinery Process Area. Stormwater runoff from within the Refinery Process	4.3 Air Quality 4.7 Geology, Soils, and Seismicity 4.9 Hydrology 4.13 Public Safety

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	Area is collected in the stormwater conveyance system and treated by the on-site wastewater treatment facility. Any sediment and/or residual contaminants in the runoff would be treated prior to discharge under the facility's NPDES Permit.	
21. Policy LU5.3: Land Use Compatibility Minimize conflicts between land uses to protect wetlands, marshlands, and creeks, human and environmental health and safety, preserve community character and retain job generating activities that have long-term viability. Types, intensities and ranges of use and development should be compatible with existing uses and should minimize or eliminate conflicts that adversely impact wetlands, marshlands, creeks, mudflats, public safety, human or environmental health or generate nuisances. All new development must avoid or mitigate to the greatest extent feasible potential negative impacts such as noise, odors, and pollution. Consistent with the City's Industrial Buffer Zone Ordinance, prohibit the location of residential uses in the area between Harbour Way South and Marina Way South and between Interstate 580 and Hall Avenue. Encourage existing larger industries that have surplus land to develop modern industrial parks that could attract new and existing industries and facilitate a reduction of existing and future land use	The Project is consistent with this Policy. The Project is located almost entirely on Project site, and the areas where most of the Project would be constructed and operated do not include wetlands, marshlands, and creeks. As described in <i>Section 4.9, Hydrology and Water Quality</i>, the Facility is served by its own wastewater system and there would be no net increase in wastewater. The waste streams at the Facility are treated by the Facility's wastewater treatment plant prior to discharge, and would continue to be required to comply with NPDES discharge limitations after installation of the Project. In addition, the Project includes a commitment to no net increase of criteria air pollutants, greenhouse gases, and public health risks from air pollution. . As described in <i>Section 4.3, Air Quality</i>, the Project would achieve these objectives through a combination of Emission-Reduction Project Design Features, which are required to be implemented as mitigation measures, and other specific, feasible mitigation measures to reduce emissions. In addition, through construction and after installation of the Project, the Facility would continue to comply with all Conditional Use Permit conditions and with the Facility's air quality and water quality permits, further ensuring that the Project would not result in land uses conflicts that adversely impact human or environmental health. In addition, as discussed in <i>Section 4.11, Noise</i>, and <i>4.3, Air Quality</i>, the Project would include mitigation measures to address any potential increase in noise or odors, would continue to comply with City and BAAQMD regulations, and would not result in any adverse noise or odor impacts. The Project would have no adverse impact on the character and scale of existing neighborhoods or landscapes because the Project is located almost	4.1 Aesthetics, Visual Quality, Light, and Glare 4.3 Air Quality 4.4 Biological Resources 4.5 Cultural Resources 4.10 Land Use, Plans, and Policies 4.11 Noise

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
conflicts. New development should complement the character and scale of existing neighborhoods, cultural resources, historic structures and landscapes. In particular, existing industrial and residential uses can successfully coexist through well-conceived circulation and urban design strategies including buffers (which may be in the form of sound walls and/or enclosed buildings and appropriate transitional habitat zones between wetlands, marshlands, creeks, and mudflats) and transitional uses, rerouting of truck traffic and design components that mark transitions in land use. Similar to other cities that host mixed uses, consider requiring land use covenants for new development in areas where new uses may generate a perception of conflict with existing uses. Require sufficient visual open space and/or landscaped screening between industrial operations and adjacent residential or recreational activities in order to create adequate buffers. See also: ED7.2; ED8.2; SN4.2	entirely on Facility property that has been previously disturbed. Finally, the Project would modernize the Facility and provide Chevron more flexibility in its Refinery Operations to meet market demands, thereby retaining job generating activities at one of Richmond's largest employers.	
22. Action LU5.C: Industrial Use Buffers – Expanded Definition New industrial uses established adjacent to existing residential or commercial uses shall incorporate measures to minimize impacts to residential uses such as enclosure of industrial activities in buildings, use of screening for visually unattractive	The Project is consistent with this Action. The Project would install equipment within the existing Facility and does not establish any new residential or commercial uses. The closest distance between the Project and a residential neighborhood is 0.2 mile (Hydrogen Plant Construction Equipment Storage and Staging Area to Point Richmond Neighborhood.) The Hydrogen Plant Construction Equipment Storage and Staging Area is buffered from the Point Richmond Residential Neighborhood by existing offices and parking areas	4.10 Land Use, Plans, and Policies

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
uses, site design, soundproofing and landscaping. New residential and commercial uses established adjacent to existing industrial uses shall incorporate measures to minimize impacts to residents from noise, exposure to toxic substance emissions, vibration, odors and truck traffic. Industrial sites may incorporate supporting office and commercial space if protected to commercial standards. See also: ED7.B	along the Facility’s perimeter and by I-580. The Project also would not include any construction within the vacant land areas near the Facility’s southern and eastern perimeter, which serve as an “internal refinery buffer area.” As described in <i>Section 4.11, Noise</i>, the Project construction and operation would not result in any perceptible increase in noise in the nearest receiving residential areas, and would comply with all applicable noise standards. The Project would also not result in any odor or truck traffic impacts to neighboring residences.	
IV. CIRCULATION ELEMENT		
23. GOAL CR3 A Safe and Well-Maintained Circulation System In order to create a safe and efficient circulation system, emphasize on-going street maintenance and safety improvements that consider all modes of transportation including walking, bicycling and public transit. Require new facilities and infrastructure as development occurs in order to meet the needs of all users while enhancing mobility and connectivity.	The Project is consistent with this Goal. As described in <i>Section 4.16, Transportation and Traffic</i>, the Project as mitigated would not result in any adverse traffic impacts and would not create any need for new transportation infrastructure. As a greenhouse gas mitigation measure, the Project includes funding for the Proposed Community Greenhouse Gas Reduction Program, which is anticipated to include funding for programs to improve bicycle and pedestrian access within the City of Richmond.	
24. Policy CR 1.D Bicycle, Pedestrian and Trail Include requirements for adequate, safe and accessible bicycle parking, drinking fountains, public restrooms, benches, landscaping and lighting. Require new development and redevelopment projects to be pedestrian and bicycle-friendly, and to provide adequate	The Project is consistent with this Policy. As described in <i>Section 4.16, Transportation and Traffic</i>, the Project as mitigated would not result in any adverse traffic impacts and would not create any need for new transportation infrastructure. As a greenhouse gas mitigation measure, the Project includes funding for the Proposed Community Greenhouse Gas Reduction Program, which is anticipated to include funding for programs to improve bicycle and pedestrian access within the City of Richmond.	4.8 Greenhouse Gases 4.10 Land Use, Plans, and Policies 4.16 Transportation and Traffic

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
connections to the existing and proposed bicycle and pedestrian network. Require all new commercial, industrial and residential development to provide access for construction and operation of a trail where a local or regional trail is designated or planned. Include provisions that require owners of property along the shoreline to provide maximum feasible public access to the shoreline and to complete the Bay Trail as part of any project approval process.	Additionally, because the Project would be constructed almost entirely on the Project site, away from the public shoreline of the Bay, the shoreline area would not be directly or indirectly affected. The Project would not alter the San Francisco Bay Trail segments planned along the shoreline. Thus, the Project does not interfere with access for construction and operation of the Bay Trail or any other planned or designated public trail.	
25. Policy CR 3.3 Concurrent Infrastructure Development Require concurrent infrastructure development for new and redevelopment projects that may have a significant adverse impact on the existing circulation system including streets, trails, sidewalks, bicycle paths and public transit.	The Project is consistent with this Policy. As described in <i>Section 4.16, Transportation and Traffic</i> , the Project as mitigated would not result in any adverse traffic impacts and would not create any need for new transportation infrastructure. As a greenhouse gas mitigation measure, the Project includes the Proposed Community Greenhouse Gas Reduction Program, which is anticipated to include funding for programs to improve bicycle and pedestrian access within the City of Richmond.	4.16 Transportation and Traffic
V. HOUSING ELEMENT		
26. Policy H-1.2: Adequate Supply of Housing Sites Ensure an adequate supply of housing sites to achieve the City's Regional Housing Needs Allocation numbers for the 2007-2014 planning period.	The Project is consistent with this Policy because the City's existing housing supply would be adequate to meet any increase in housing demand due to new temporary or full-time employees associated with the Project, as described in <i>Section 4.12, Employment, Population, and Housing</i> .	4.12 Employment, Population, and Housing
VI. COMMUNITY FACILITIES ELEMENT		
27. Policy CF1.4 Concurrent Infrastructure Development Require new development to provide proportionate	The Project is consistent with this Policy. As described in the relevant EIR sections relating to each resource (<i>Section 4.17, Utilities and Service Systems, 4.15, Parks and Recreation, and 4.16, Transportation and Traffic</i>) the Project	4.17 Utilities and Service Systems 4.15 Parks and

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
facilities and infrastructure improvements as it occurs. New developments must mitigate impacts or contribute adequate infrastructure to meet additional demand for roads, parks, schools and utilities.	would not result in any additional demand for roads, parks, schools or utilities.	Recreation 4.16 Transportation and Traffic
VII. CONSERVATION, NATURAL RESOURCES, AND OPEN SPACE ELEMENT		
28. GOAL CN1: Preserved and Restored Natural Habitat and Biodiversity Continue to preserve and restore natural habitat and associated plants and wildlife including wetlands, baylands, riparian areas, oak woodlands and other sensitive biological resources. Take restoration efforts such as controlling invasive species, re-establishing natives, daylighting creeks and reclaiming priority conservation areas in order to maintaining critical habitat and biodiversity. Carefully balance natural lands, habitat and protection of multiple species with the need to accommodate development.	The Project is consistent with this Policy. The Project would be constructed almost entirely within the previously-developed Refinery Process Area, which does not provide potential habitat for special status species. Placement and construction of Project components would have no significant adverse impact on biological resources. Continued compliance with the Facility's NPDES permit would protect against any impact to any biological resources from wastewater discharges, and the Project as proposed would not result in any net increase in wastewater.	4.4 Biological Resources 4.9 Hydrology
29. GOAL CN5: Environmental Sustainability Reduce the City's carbon footprint and manage resources wisely to meet the needs of a growing population and economy. Base community planning decisions on sustainable practices that reduce environmental pollutants, conserve resources, and minimize waste. Lead the Bay Area in reducing dependence on fossil fuels by encouraging design of energy efficient buildings, using renewable	The Project is consistent with this Goal. Although the Facility produces fossil fuel products, the proposed Project would not increase the Facility's capacity and would modernize the Facility's existing equipment. A core Project objective is to replace some existing equipment and install new equipment with Project Components that are more energy efficient and therefore produce fewer greenhouse gas emissions. As described in 3.0, <i>Project Description</i> , as part of the Project, heat exchangers and other equipment used to transfer heat energy at the fluidized catalytic cracker feed hydrotreater (FCC FHT) unit would be modified to improve energy efficiency, allowing for additional throughput without requiring additional permitted heat input at the unit's furnaces. A new	3.0 Project Description 4.3 Air Quality 4.4 Biological Resources 4.7 Geology, Soils, and Seismicity 4.9 Hydrology and

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
energy and promoting alternative methods of transportation. See also: LU4.2; EC2.1; EC3.2; EC3.B; EC 3.3; CN5.2; CN5.1, CN5.A; HW9.6; HW10.5; HW10.D	power recovery turbine would also be installed at the FCC FHT unit, which would use changes in operating pressures within the unit to produce electricity, offsetting electricity demand. Also, the new hydrogen plant would be equipped with newer technology including pressure swing absorption that is less fuel intensive and results in reduced fuel usage per hydrogen product, as well as a new steam turbine generator, which would offset electricity and fuel demand throughout the Facility. The new hydrogen plant would also allow for collection and reuse of refinery fuel gas in lieu of imported natural gas. Additionally, the Project would upgrade motors which drive the cooling fans in the Fluid Catalytic Cracker cooling water tower to adjustable speed direct drive motors which are more energy efficient. The Project would also upgrade approximately 6,000 lighting fixtures in the process plant areas of the Facility with LED lighting, reducing the Facility's energy demand for lighting. In addition to these energy efficiency measures at the Facility, the Project would also include off-site Project Design Features that would create energy efficiency and reduce greenhouse gas emissions within the community, including Chevron's participation in Marin Clean Energy for some Chevron facilities, and the funding of the proposed Community Greenhouse Gas Reduction Program, which is anticipated to include weatherization of existing residential and commercial buildings, a proposed utility-scale solar installation, and funding for existing programs supporting installation of solar energy on residential and commercial buildings. The Community Greenhouse Gas Reduction Program is also anticipated to include funding for programs to improve bicycle and pedestrian infrastructure within the City of Richmond. The Project is also consistent with this policy in that it is designed to reduce pollutants by committing to no net increase of criteria air pollutants and greenhouse gases, and no net increase in public health risks from air pollution. As described in <i>Section 4.3, Air Quality</i>, and <i>4.8, Greenhouse Gases</i>, the Project would achieve these objectives through a combination of Emission-	Water Quality 4.10 Land Use, Plans, and Policies

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
30. Policy CN2.4 Agricultural Lands Preserve agricultural lands for sustained crop production, grazing and farming. Encourage local organic food production such as microfarming in community gardens and private yards. Protect viable topsoils to ensure working landscapes. See also: PR4.1; HW1.7	Reducing Project Design Features, which would be implemented as mitigation measures, and other specific, feasible mitigation measures to reduce emissions. In addition, through construction and after installation of the Project, the Facility would continue to comply with all Conditional Use Permit conditions and with the Facility's air quality permits, further ensuring that any environmental or health impacts would be minimized. Also, as discussed in <i>Section 4.17, Utilities, and Section 4.9, Hydrology and Water Quality</i>, the Project would result in no increase in solid waste, and no increase in discharges of pollution to water. The Project is consistent with this Policy. The Project would be constructed almost entirely within the Facility where there are no agricultural or grazing lands. Because the Project would result in no net increase in emissions from criteria pollutants and greenhouse gases, and no net increase in public health risks from air pollution, the Project would not result in any net increase in air deposition of pollutants on any locally-grown produce, including backyard and community gardens.	4.3 Air Quality 4.8 Greenhouse Gases 4.10 Land Use, Plans, and Policies
31. Policy CN2.6 Protect Soil and Reduce Erosion Minimize soil depletion and erosion. Prevent erosion caused by construction activities. Retain natural vegetation and topography and minimize grading of hillsides.	The Project is consistent with this Policy. Most of the construction for the Project is already complete. During the remaining Project construction, significant new excavation activities would not be undertaken in areas of the Facility that are not already developed. Since construction of most of the Project would occur in the previously-developed Refinery Process Area of the site, erosion impacts would not be anticipated.	4.7 Geology, Soils, Seismicity, and Mineral Resources
32. Policy CN2.7 Parkland Preservation Maintain high quality parklands and play areas to serve current and future residents. Require new development and redevelopment projects to provide additional parkland or funding to purchase and maintain parklands.	The Project is consistent with this Policy. As discussed in <i>Section 4.15, Parks and Recreation</i>, the Project does not include parks or recreational facilities nor would the Project require the expansion or construction of any recreational facility based on any temporary or permanent increase in population associated with the Project.	4.15 Parks and Recreation

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
33. Policy CN2.8 Mineral Resources Preserve mineral resources in undeveloped areas that have been classified by the State Mining and Geology Board as having statewide or regional significance for possible future extraction. Avoid nuisances, hazards or adverse environmental, public health and safety impacts associated with mineral extraction by employing methods such as development setbacks, buffers, screening and other appropriate measures. In locations where mineral extraction is no longer a viable practice, provide environmentally sensitive remediation and reuse.	The Project is consistent with this Policy. The Facility, which is considered a heavy industrial use, has operated on this site for over 100 years. Despite some potential for mineral resources to be present beneath the site, the existing Facility processing units and operations preclude access to any potential resources. The Project components would be located primarily within the previously developed Refinery Process and Tank Farm areas, that is, on land where access to mineral resources is already precluded.	4.7 Geology, Soils, Seismicity, and Mineral Resources
34. Policy CN3.1 Stormwater Management Develop strategies to promote stormwater management techniques that minimize surface water runoff in public and private developments. Utilize low-impact development techniques to best manage stormwater through conservation, on-site filtration and water recycling. See also: CN3.2, HW9.3	The Project is consistent with this Policy. While some of the Project components would include new impervious surfaces, the existing surface soils are highly compacted and frequently underlain by shallow bedrock, so that existing infiltration rates are already limited. Therefore, the proposed new impervious cover is not expected to cause a substantial increase in surface water runoff rates or volumes. None of Project components or facilities would substantially alter drainage patterns (e.g., redirect stormwater runoff from one sub-basin to another). All proposed excavation related to the Project would be conducted entirely within the Refinery Process Area. Stormwater runoff from within the Refinery Process Area is collected in the stormwater conveyance system and treated by the Facility's wastewater treatment facility. Any sediment and/or residual contaminants in the runoff would be treated prior to discharge under the facility's NPDES permit.	4.9 Hydrology and Water Quality
35. Policy CN3.3 Flood Management Minimize the flood hazard risks to people, property and the environment. Address potential damage from a 100-year flood, tsunami, sea level rise and	The Project is consistent with this Policy. The Project is located on a hilly peninsula that extends into the Bay; the Federal Emergency Management Agency flood zones (Zone VE) mapped around most of the perimeter of the peninsula are related to coastal flooding hazards (e.g., high tides and storm	4.9 Hydrology and Water Quality

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
seiche, and implement and maintain flood management measures in all creeks and in all watersheds. See also: SN1.2	surges) (FEMA, 2009). Placement of structures within coastal flooding zones would not adversely impede or redirect flood flows toward some other vulnerable area because the structures would not affect the water levels in the Bay or the energy of surges or waves elsewhere. The Modernization Project includes ongoing use of Facility equipment in areas subject to coastal flooding, including tsunami wave runup and sea level rise. A tsunami in San Francisco Bay is a low probability event, and Chevron has a plan in place for addressing this and other flood-related risks, and as mitigation the Project would require Chevron to develop a contingency plan that addresses sea level rise. The Modernization Project does not result in any incremental increase in these flood-related Facility risks.	
36. Policy CN3.4 Water Conservation Promote water conservation. Encourage residents, public facilities, businesses and industry to conserve water especially during drought years. Work with East Bay Municipal Utility District to advance water recycling programs including using treated wastewater to irrigate parks, golf courses and roadway landscaping and by encouraging rainwater catchment and graywater usage techniques in buildings. See also: EC3.4; EC4.3	The Project is consistent with this Policy. The Modernization Project includes as a Project Design Feature Facility water reuse projects to reduce EBMUD water consumption and wastewater discharge. These projects would be included in a mitigation monitoring and reporting program. The Project would be served by reclaimed water produced by an existing EBMUD facility which has the capacity to do so, and the Project's water demands are included in the approved EBMUD Urban Water Management Plan which confirms the availability of adequate water supplies for the Facility, as discussed further in <i>Section 4.17, Utilities</i>.	4.9 Hydrology and Water Quality 4.17 Utilities and Service Systems
37. Action CN4.C Climate-Friendly Fuel Using Vehicles Support the use of highly efficient climate-friendly fuel using vehicles, adequate alternative refueling stations and the use of waste for producing fuel where feasible or rational.	The Project is consistent with this Action. The Project would include the proposed Community Greenhouse Gas Reduction Program, which is anticipated to include funding for electric vehicle purchase rebates and charging stations within the City. Also, the Project would enable the Facility to continue manufacturing fuel products that meet California's stringent fuel regulations.	4.8 Greenhouse Gases

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
See also: EC2.A; CR5.C		
38. Action CN6.B Hazardous Substance Management Implement standards dealing with the safe management of hazardous substances in close coordination with the City Fire Department and the Department of Toxic Substance Control. The standards should require soil testing at development sites where contamination is suspected, address safe household hazardous and universal waste disposal and ensure compliance with hazardous substance regulations and safe transport of hazardous materials. Use of the latest technologies available should be considered when conducting remediation in order to expedite the cleansing process and do the least harm to the environment. See also: HW9.K	The Project is consistent with this Action. Petroleum refining operations inherently involve the routine use, transport, and disposal of hazardous materials. Wastes generated are subject to extensive applicable regulations regarding storage and disposal, as described in <i>Section 4.13, Public Safety</i>. Because the Project would involve mainly replacement units using identical or similar technologies, the waste streams generated from the new units would be very similar to those currently generated. Thus, there would be no new categories of hazardous wastes generated. While the quantities of some hazardous materials would change, as described in <i>Section 4.13, Public Safety</i>, quantities of stored hazardous materials specific to the Modernization Project would be less than maximum quantities currently stored at the Facility. After installation of the Project, the Facility would continue to send most of the material off-site for reclamation of precious metals, while the remainder would be transported to a secure landfill that is licensed to accept these wastes. In addition, the type of waste that would be increased (solid spent catalyst) would be much less hazardous than the waste being eliminated (liquid spent monoethanolamine (MEA)); therefore, the consequences of an accidental spill of solid waste during transport would be less after the Project compared to the Facility today. The Modernization Project would require mitigation measures including updates of Chevron's Risk Management Plan, Safety Plan, Hazardous Materials Business Plan, SPCC Plan and Facility Response Plan, prior to the operation of the Project, and the reclamation or proper disposal of spent catalyst associated with the Project. Most of the construction for the Project, including excavation activities, is already complete. During the remaining Project construction, it is estimated that approximately 500 tons of potentially hazardous soil would be excavated prior to and during the construction of elements of the Project. Any soil	4.13 Public Safety

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	determined to be hazardous would be handled and stored as hazardous waste until it is disposed of at hazardous waste disposal facilities. Non-hazardous soil would be reused on site or would be sent off-site as a designated waste, as required by regulations. As described in <i>Section 4.13, Public Safety</i> , the Project would include additional measures to ensure that impacts to the public and environment from the use, storage, transport or disposal of hazardous materials during construction would be minimized, including: mitigations requiring construction materials storage only in authorized locations; measures requiring transportation of these wastes off-site within the specified timeframes and in compliance with existing regulations; and measures requiring implementation of enhanced refinery and contract worker safety procedures for construction activities, as part of Chevron's enhanced safety program developed following the August 2012 fire.	
VIII. ENERGY AND CLIMATE CHANGE ELEMENT		
39. Action EC2.K Engine Replacement and Retrofitting: Work with the Bay Area Air Quality Management District to develop a program to fund diesel engine retrofitting or replacement in existing automobiles, trucks, rail, ships and equipment. Regularly identify feasible technologies that can be applied for retrofitting polluting vehicles. Collaborate with key stakeholders to develop and implement the program.	The Project is consistent with this Policy. As described in <i>Section 4.3, Air Quality</i> , the Project would upgrade main ship diesel engines to meet Tier 3 standards and upgrade auxiliary engines with turbochargers.	4.3 Air Quality
40. Policy EC3.1 Renewable Energy: Promote the generation, transmission and use of a range of renewable energy sources such as solar, wind power and	The Project is consistent with this Policy. As described in <i>Section 4.8, Greenhouse Gases</i> , the Project may include a 2-megawatt solar facility as a mitigation menu option which would offset approximately 643 MT CO ₂ e. In addition, as a project design feature, the Project would participate in MCE for	4.8 Greenhouse Gases

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
waste energy to meet current and future demand and encourage new development and redevelopment projects to generate a portion of their energy needs through renewable sources.	its commercial and industrial electricity accounts. MCE sources its electricity from a higher percentage of renewable sources compared to PG&E.	
41. Policy EC2.2: Climate-Friendly Fuel Support production and distribution of climate-friendlier fuels (when and if any are identified) and identify appropriate locations for fuel storage and distribution.	The Project is consistent with this Policy. The Project would enable the Facility to continue manufacturing fuel products that meet California's stringent fuel regulations. The Facility currently includes an extensive research and development operation, including a 1.2-million-square-foot research campus where employees research fuel-efficient transportation products and explore renewable and alternative energies including biofuels, solar and geothermal power. The Project, while not directly involving or expanding the research and development operation, would support continuation of this research at the Facility by allowing the Facility more flexibility in its operations to meet market demand.	4.6 Energy 4.8 Greenhouse Gases 4.9 Hydrology and Water Quality
42. Policy EC2.7 Climate-Friendly Goods Movement: Promote the safe and efficient movement of goods by truck, rail and ship to support port operations and industrial uses.	The Project is consistent with this Policy. As a mitigation measure, the Facility would increase the average "parcel size" - the average ship cargo volume that is delivered or picked up from the Richmond Long Wharf - to reduce the number of ship calls, and thereby reduce NOx emissions and greenhouse gas emissions related to shipping.	4.3 Air Quality
43. Policy EC6.3: Adapting to Climate Change Prepare for and adapt to future impacts of changing weather patterns and sea level fluctuations. Protect neighborhoods, infrastructure and facilities, the shoreline and natural resources from the impacts of climate change. Require new developments to include an evaluation of climate change impacts in the project review process. Shoreline and public	The Project is consistent with this Policy. The Project would be built almost entirely within the Refinery Process Area, and does not involve any development at the shoreline. The Modernization Project includes ongoing use of Facility equipment in areas subject to coastal flooding, including tsunami wave runup and sea level rise. A tsunami in San Francisco Bay is a low probability event, and Chevron has a plan in place for addressing this and other flood-related risks, and as a mitigation measure, the Project would require Chevron to develop a contingency plan that addresses sea level rise.	4.8 Greenhouse Gases 4.9 Hydrology and Water Quality

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
access improvements shall be designed to allow future increases in elevation along the shoreline edge to keep up with higher sea level values, when they occur. Design elements shall include providing adequate setbacks to allow for future elevation increases of at least 3 feet from the existing elevation along the shoreline.	The Modernization Project does not result in any incremental increase in these flood-related Facility risks.	
44. Action EC6.F: Disaster Preparedness and Recovery Plan Require that all development and redevelopment projects comply with the City's Disaster Preparedness and Recovery Plan. Regularly review and update the plan and expand public training and information. See also: SN3.A; HW3.D; CF2.D	The Project is consistent with this Action. The City of Richmond has a Community Guide to Emergency Preparedness (Guide), which was published by the Richmond Fire Department Office of Emergency Services in May 2011 (FRD OES, 2011). The Guide contains information such as locations and contact information for local hospitals, transportation services, utilities, and petrochemical plants. The Facility has in place numerous existing emergency preparedness and response procedures and plans, and these would be required to be revised prior to commencement of Project operations to incorporate changes associated with the Modernization Project. The Facility would be required to mitigate potential impacts by revising its emergency response plan, and developing Emergency Operating Procedures, for new and modified Project equipment. The revised Safety Plan would be submitted to CCHS for approval prior to Project operations.	4.13 Public Safety
IX. GROWTH MANAGEMENT ELEMENT		
45. GOAL GM2 Improved Infrastructure and Facilities Improve public services and infrastructure to meet the demands of new development.	The Project is consistent with this Goal. As described in <i>Section 4.16, Transportation and Traffic</i> , the Project as mitigated would not result in any adverse traffic impacts and would not create any need for new transportation infrastructure. As a greenhouse gas mitigation measure, the Project includes the Proposed Community Greenhouse Gas Reduction Program, which is anticipated to include funding for programs to improve bicycle and pedestrian access within the City of Richmond. Also, the Project would not create new demand for public services such as parks and recreation, schools, emergency	4.6 Transportation 4.14 Public Services 4.15 Parks and Recreation 4.17 Utilities and Service Systems

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	services, or additional public utilities.	
46. Policy GM2.2 Community Amenities for New Development Require new development to pay costs attributable to that development including impacts on: local streets; local and regional transportation systems; and public facilities such as parks and recreation, schools and emergency services.	The Project is consistent with this Policy. The Project is subject to applicable impact fees for industrial projects.	
XI. HEALTH AND WELLNESS ELEMENT		
47. Policy HW3.3: Emergency and Disaster Preparedness Maintain staff and facilities that will continue to support a coordinated and effective response to emergencies and natural disasters throughout the City. Coordinate with neighboring jurisdictions, local employers and industries to make sure that emergency preparedness and disaster response programs equitably serve all parts of the City. Continue to maintain adequate police and fire staffing, facilities, equipment and maintenance in order to protect the community. See also SN3.1; SN3.E	The Project is consistent with this Policy. The Facility has in place numerous existing emergency preparedness and response procedures and plans, and these would be required to be revised prior to commencement of Project operations to incorporate changes associated with the Modernization Project. Revisions to the Risk Management Plan and the site Safety Plan to reflect the Project's modified and new equipment are required by CalARP and the RISO. The Facility would also update its Hazardous Materials Business Plan to reflect Project-related information for emergency response planning purposes. The Facility would also submit a revised Spill Prevention Control and Countermeasure plan and a revised Facility Response Plan to reflect modified and new Project equipment. The Project as proposed includes requirements for additional Richmond and Chevron Fire Department training that Chevron will fund and coordinate with the Richmond Fire Department prior to commencement of Project operations, and will occur annually throughout Project operations. The Project would require that Facility personnel and contractors are trained on the revised emergency procedures, and that annual refresher training is provided. In addition, as a requirement of the Facility's plea agreement with the State of California entered into on August 5, 2013, the Facility is developing and implementing additional emergency response	4.13 Public Safety 4.14 Public Services

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
48. Policy HW8.3: Property Maintenance Encourage private landowners to maintain and upgrade their property in neighborhoods, commercial corridors and industrial areas. Protect viable neighborhoods and commercial areas from adverse impacts of vacant and underutilized sites and blighted buildings and structures.	training for incident commanders, first responders, and operations management and employees to include training on leak response protocol and shutdown decisions, setting up incident commence structures and establishing boundary limits, and evaluating "hot zones." As a mitigation measure, the Facility would update these training programs prior to commencement of Project operations to incorporate Project equipment and conditions. The Chevron Fire Department would continue to support the Contra Costa County Hazardous Materials Area Plan with equipment and trained personnel. As discussed in <i>Section 4.17, Utilities</i> , the Project would not result in the need for additional emergency response facilities.	4.10 Land Use, Plans, and Policies
XII. PUBLIC SAFETY AND NOISE ELEMENT		
49. Goal SN1: Risk Management of Natural and Human-Caused Disasters Minimize the risk of injury, loss of life, property damage and environmental degradation from	The Project is consistent with this Goal of minimizing the risk from natural and human-caused disasters. Specifically, with respect to the risk of injury, loss of life, property damage and environmental degradation from fire and handling and transport of hazardous materials, as described in <i>Section 4.13, Public Safety</i> , the Project would include enhanced safety measures at the Facility in	4.7 Geology 4.9 Hydrology and Water Quality 4.13 Public Safety

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
seismic activity, geologic hazards, flooding and fire and the storage, use and transport of hazardous materials and operations. Promote a sustainable approach to reduce impacts of natural disasters such as flooding and fire.	addition to continued compliance with all regulatory requirements. Specifically, the Facility would continue to comply with extensive federal, state, and local regulations on safety, disaster preparedness, and emergency planning, preparedness and response, including: ▪ RMP requirements under California Accidental Release Program regulating hazard assessment, release prevention, and emergency response planning. The Facility's RMP was updated Feb 2013 in response to the August 2012 fire, and would be updated again prior to commencing operation of the Project to incorporate changes associated with the Project; ▪ City/County Industrial Safety Ordinances, as amended in response to recommendations made by the Chemical Safety Board in response to the August 2012 fire; ▪ Process Safety Management requirements under Cal/OSHA requiring process hazard analyses for all process units; and ▪ State hazardous materials inventory/business plan regulations, implemented by Contra Costa Health Services. In addition, changes to Facility processes are being made based on U.S. Chemical Safety and Hazard Investigation Board (CSB) recommendations and other investigations following the August 2012 fire, including the terms of a probation agreement. As described in <i>Section 4.13, Public Safety</i>, these changes include implementing a new regime of pipe thickness and corrosion risk inspections, damage mechanisms reviews, process hazard analyses, enhanced emergency response training, record-keeping, and reporting requirements. The proposed Project includes implementation of a new Modernization Reliability Program designed to further enhance safety and reliability of Facility equipment and Refinery Operations. The Modernization Reliability Program commits Chevron to replacing numerous piping circuits, installing additional	

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	monitoring devices on certain carbon steel piping circuits, implementing new inspection, sampling, and monitoring regimes, and a system of verifying post-Project operating conditions when the sulfur content of crude oil being processed at the Facility reach specified levels. The Modernization Reliability Program also requires that process hazard assessments be conducted or revalidated prior to construction and again after construction prior to commencement of Project operations, and that these process hazard assessments include inherently safety systems analysis, layers of protection analysis, and damage mechanism evaluations. The Modernization Reliability Program requires Chevron to convene annual town hall meetings to brief the community on safety improvements, and requires Chevron to submit annual reports to the City on the status and progress of Reliability Program requirements. The Modernization Reliability Program is included in its entirety in <i>Section 4.13 Appendix 4.13-REL</i>. All safety and reliability measures are described in <i>Section 4.13, Public Safety</i>. In addition, the Project would include implementation of an open space fire protection plan to reduce fuel loading in vegetated open space areas adjacent to the Refinery Process Area, and to minimize risks of fire occurrence and fire size, as described in <i>4.13, Public Safety</i>. With implementation of these mitigation measures, the Project would be consistent with this Goal of minimizing risk from fires. With respect to risks from use and transport of hazardous materials, with the Project there would be no new categories of hazardous wastes generated. While the quantities of some hazardous materials would change, as described in <i>Section 4.13, Public Safety</i>, quantities of stored hazardous materials specific to the Modernization Project would be less than maximum quantities currently stored at the Facility. The Facility would continue to send most of the material off-site for reclamation of precious metals, while the remainder would be transported to a secure landfill that is licensed to accept these wastes. The	

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	type of waste that would be increased (solid spent catalyst) would be much less hazardous than the waste being eliminated (liquid spent MEA); therefore, the consequences of an accidental spill of solid waste during transport would be less after the Project compared to the Facility today. In addition, during Project construction the Project would continue to comply with all applicable regulations, and would include additional mitigation measures to ensure that impacts to the public and environment from the use, storage, transport or disposal of hazardous materials during construction would be minimized, as described in detail in <i>Section 4.13, Public Safety</i>. Because the Project would be built almost entirely within the previously-developed Refinery Process Area, the Project would not result in any increased risk from seismic activity, geologic hazards, or flooding, as described in <i>Sections 4.7, Geology, Soils, Seismicity, and Mineral Resources</i>, and <i>4.9, Hydrology and Water Quality</i>.	
50. Goal SN2: High Levels of Police and Fire Service Provide a high level of security in the community to prevent and reduce crime, and minimize risks to people, property and the environment from fire. See also: SN2.2	The Project is consistent with this Policy. The Chevron Fire Department would continue to work closely with the Richmond Fire Department to prepare for and respond to emergencies at the Facility. The Facility would be required to update its emergency response plans and procedures to reflect Project equipment and operating conditions, and provide training to the Richmond Fire Department prior to commencement of Project operations. As discussed in <i>4.13 Public Safety</i> and <i>4.14 Public Services</i>, any increased demand for police or fire services associated with construction or operation of the Project would not exceed the capacity of existing fire and police services, as provided by the Chevron Fire Department, and the Richmond Police and Fire Departments. In addition, on December 19, 2013, Chevron and the City entered into a 5-year Agreement for Fire Prevention Services under the terms of which Chevron will fund a full-time Fire Inspector II position to be embedded at the Facility. This Fire Inspector will review, analyze, issue, inspect, extend, and close all Fire Construction Permits, and maintain and renew as appropriate the Annual	4.13 Public Safety; 4.14 Public Services

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
51. Goal SN3: Emergency Preparedness Develop effective mechanisms for a coordinated response to emergencies and natural disasters to best protect residents, businesses and the environment.	Operating Permit issued pursuant to the California Fire Code. The funding under the agreement compensates the City of Richmond for all personnel costs associated with the Fire Inspector II position as well as all permit fees (Judd, 2013). Chevron also has an ongoing contract with the City of Richmond for the services of one full-time on-site code enforcement officer for building and construction (Ayers, 2013). Additionally, the Project would include an enhanced emergency response training program, as described in <i>Section 4.13, Public Safety</i>, as well as an open space fire protection plan to reduce fuel loading in vegetated open space areas adjacent to the Refinery Process Area, and to minimize risks of fire occurrence and fire size. The Project is consistent with this Goal. The Chevron Fire Department would continue to work closely with the Richmond Fire Department to prepare for and respond to emergencies at the Facility. The Facility would be required to update its emergency response plans and procedures to reflect Project equipment and operating conditions, and provide training to the Richmond Fire Department prior to commencement of Project operations. The Facility has an emergency notification system with requirements for notifying off-site emergency responders, government agencies, the community, and local hospitals in the event of a release. The Facility participated in the development of the community warning system and the telephone emergency notification system, and has its own notification systems through sirens, radios, emergency alert receivers, and the media. As part of the Project, Chevron would also make small radio devices available to the community and schools as a notification method for emergencies. Chevron would mitigate risks by coordinating with local area schools to ensure that the Facility's emergency response procedures and plans are adequate to minimize risk to school children, including updating plans/procedures, providing emergency response equipment, and providing training to school	4.13 Public Safety

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
52. Goal SN4: Acceptable Noise Levels Achieve noise levels consistent with acceptable standards and reduce or eliminate objectionable noise sources. Prevent where possible, or mitigate noise impacts from industries, roadways, railroads and businesses in residential areas and sensitive uses in the community. In addition, apply new technology, buffers and other solutions to reduce excessive noise. See also: SN4.1	staff. Chevron will report all spills and releases of hazardous materials or hazardous waste to the environment, including those from the transportation of these materials, within 48 hours to the City and to the appropriate regulatory agency. With the Project, Chevron would prepare and implement an open space fire protection plan that would include provisions for emergency response coordination, including enhanced mutual aid, protocols to assure adequate firefighter responses to open space area fires as well as Refinery area. The Project is consistent with this Goal. As described in <i>Section 4.11, Noise</i>, modeled levels of concurrent operation of all construction equipment would comply with Richmond Noise Ordinance. The increase over existing daytime ambient sound levels would be 1 to 2 A-weighted decibels (dBA), a less-than-perceptible change. In addition, modeling of noise associated with Refinery Operations after installation of the Project showed that the Project would not result in any increase in noise at the nearest residential receptors.	4.11 Noise
53. Policy SN1.3: Hazardous Materials Operations Require safe production, transportation, handling, use and disposal of hazardous materials that may cause air, water or soil contamination. Encourage best practices in hazardous waste management and ensure consistency with City, West Contra Costa County and Cal/OSHA guidelines, standards and requirements. Protect Richmond's shoreline and other natural resources from accidental occurrences by controlling the location of new hazardous waste facilities and by limiting the expansion of existing	The Project is consistent with this Policy. Petroleum refining operations inherently involve the routine use, transport, and disposal of hazardous materials. Wastes generated are subject to extensive applicable regulations regarding storage and disposal, as described in <i>Section 4.13, Public Safety</i>. Because the Project would involve mainly replacement units using identical or similar technologies, the waste streams generated from the new units would be very similar to those currently generated. Thus, there would be no new categories of hazardous wastes generated. However, the quantities of some hazardous materials would change, as described in <i>Section 4.13, Public Safety</i>. After installation of Project, the Facility would continue to send most of the material off-site for reclamation of precious metals, while the remainder would	4.13 Public Safety

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
hazardous waste facilities adjacent to the shoreline and along streams or creeks. Coordinate with federal, state and local agencies and law enforcement to prevent the illegal transportation and disposal of hazardous waste.	be transported to a secure landfill that is licensed to accept these wastes. The type of waste that would be increased (solid spent catalyst) would be much less hazardous than the waste being eliminated (liquid spent MEA); therefore, the consequences of an accidental spill of solid waste during transport would be less after the Project compared to the Facility today. During Project construction, it is estimated that approximately 500 tons of potentially hazardous soil would be excavated prior to and during the construction of elements of the Project. Any soil determined to be hazardous would be handled and stored as hazardous waste until it is disposed of at hazardous waste disposal facilities. Non-hazardous soil would be reused on site or would be sent off-site as a designated waste, as required by regulations. As described in <i>Section 4.3, Public Safety</i>, the Project would include additional measures to ensure that impacts to the public and environment from the use, storage, transport or disposal of hazardous materials during construction would be minimized, including mitigations requiring construction materials storage only in authorized locations, measures requiring transportation of these wastes off-site within the specified timeframes and in compliance with existing regulations, and measures requiring implementation of enhanced refinery and contract worker safety procedures for construction activities, as part of Chevron's enhanced safety program developed following the August 2012 fire.	4.13 Public Safety 4.14 Public Services
54. Policy SN2.3: Fire Safety Regularly update policies that will protect the community and its urban and natural areas from fire hazards. Emphasize prevention and awareness of fire safety guidelines to minimize risk and potential damage to life, property and the environment. In areas designated by the Richmond	The Project is consistent with this Policy. The Facility has a dedicated Chevron Fire Department, and as discussed in <i>4.14 Public Services</i>, any increased demand for police or fire services associated with construction or operation of the Project would not exceed the capacity of existing fire and police services, as provided by the Chevron Fire Department, and the Richmond Police and Fire Departments. As discussed in <i>4.13 Public Safety</i>, the Facility would be required to update its emergency response plans and procedures to reflect Project equipment and operating conditions, and provide training to the Richmond	

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
Fire Department as having a high fire hazard, ensure adequate fire equipment, personnel, firebreaks, facilities, water and access for a quick and efficient response in any area.	Fire Department prior to commencement of Project operations. The Chevron Fire Department responsibilities include inspections of fire-related equipment, permit authorization for hot work and confined space entry, security, and a variety of other tasks related to fire prevention and emergency response. The Chevron Fire Department trains its personnel to handle any emergency that might occur. These emergencies involve all aspects of fire-fighting, including fires in process plants, building fires, storage tank fires, wild land fires, or fires related to transportation modes, including ships, barges, tank cars, and rail cars. Chevron Fire Department personnel are trained in confined space, high angle, and heavy rescue procedures. In addition, all of the full-time members are certified Hazardous Material Technicians, and are qualified to deal with any hazardous material incident including any oil spills at the ship and barge loading facilities. The Chevron Fire Department also responds to medical emergencies. A variety of emergency response equipment exists at the Facility and includes 25 emergency response vehicles (including fire trucks), 2,500 fire extinguishers, water deluge systems, in-plant stationary fire monitors, fixed foam systems, and a water fog system. The liquefied petroleum gas storage vessels and anhydrous ammonia storage vessels are equipped with firewater deluge systems, which have the ability to cool the vessels and disperse vapor clouds to prevent failure in case of a fire. All of this equipment is required to be maintained, inspected, and tested as outlined in the Chevron Fire Department Procedures and Policies. As part of the Emergency Response Program, the Chevron Facility works with local emergency responders in preparing for and responding to emergencies. The Facility also works closely with the CCHMP for any necessary response to hazardous material releases (such as downwind air monitoring) and to alert the public in case of accidental releases, fires, or explosions in accordance with CCHMP's Emergency Response Area Plan. Likewise, the Chevron Fire Department supports the Contra Costa County Hazardous Materials Area Plan	

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	with equipment and trained personnel. The Facility worked with CCHMP to establish the Community Warning System and the Telephone Emergency Notification System zones, which provide incident notification to the community. The Chevron Fire Department also provides mutual aid to the City of Richmond Fire Department and responds outside of the Facility within the City of Richmond whenever asked to do so by the city fire department. The Chevron Fire Department also belongs to an industrial mutual aid organization, PMAO, and has responded to other oil companies and chemical plants during emergencies. Likewise, the emergency response resources of the other companies in PMAO are available for an emergency at the Chevron Facility if needed. The Project would include an enhanced emergency response training program, as described in <i>Section 4.13, Public Safety</i>, as well as an open space fire protection plan to reduce fuel loading in vegetated open space areas adjacent to the Refinery Process Area, and to minimize risks of fire occurrence and fire size.	
55. Action SN2.C Regional Emergency Coordination Plan Collaborate with regional agencies and neighboring jurisdictions to develop and implement a regional emergency coordination plan and agreement for police, fire and emergency medical services.	The Project is consistent with this Action. After the Project, as part of the Emergency Response Program, the Facility would continue to work closely with the Richmond Fire Department and the Contra Costa County Hazardous Materials Program to coordinate emergency preparedness and response to coordinate emergency preparedness and response. Emergency response drills are conducted annually with the Richmond Fire Department and/or the CCHMP. The Facility also works closely with the CCHMP for any necessary response to hazardous materials releases and to alert the public in case of accidental releases, fires, or explosions. The Chevron Fire Department also provides mutual aid to the City of Richmond Fire Department and responds outside of the Facility within the City of	4.13 Public Safety

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
56. Action SN2.D Fire Prone Area Designation Designate areas in Richmond that are particularly prone to fire hazards and make this information available to the community. Consider adopting wildfire development guidelines for development adjacent to fire prone areas.	Richmond whenever asked to do so by the Richmond Fire department. The Chevron Fire Department also belongs to an industrial mutual aid organization, the Petrochemical Mutual Aid Organization, through which Chevron and other oil companies and chemical plants in the area are available to respond to emergencies at each other's facilities when needed. The Facility would be required to revise its emergency response plan and procedures to incorporate Project-related new and modified equipment and operating conditions prior to commencement of Project operations, and all regionally coordinated emergency response efforts would then be based on the Facility's updated emergency response plan and procedures. The Project is consistent with this Policy. The major components of the Project would be constructed entirely within the existing processing areas of the Facility, many of which are located in barren or paved areas. However, Figure 4.13-5 also shows large areas of vegetated open space near the processing areas of the Facility, including the ridge of hills that extends approximately four kilometers from the tank farms at the southeast part of the Facility to the northwest tip of the peninsula and the flat open space to the northwest of the Low Sulfur Fuel Oil flare. During the dry season, from approximately April through October, these open space areas are susceptible to fires. According to Chevron, the growth of vegetation in these areas is controlled to limit fire potential. In addition, the Facility has its own fire protection measures, including buffers between the Refinery Process Area and fence lines. As described in <i>Section 4.14, Public Services</i>, the Facility supports its own Fire Department that is staffed with full-time and volunteer personnel trained to handle all types of emergencies, including wildland fires. The Facility is also served by the Richmond Fire Department, as noted in <i>Section 4.14, Public Services</i>. As part of the Project, Chevron would prepare and implement an open space fire protection plan to reduce fuel loading in vegetated open space areas	4.13 Public Safety

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	adjacent to the Refinery Process Area, and to minimize risks of fire occurrence and fire size, as described in <i>Section 4.13, Public Safety</i> .	
57. Action SN3.C: Emergency Preparedness Exercises Continue to hold joint fire, hazardous materials incidents, disaster drills and earthquake response exercises with adjacent communities, utility companies, larger businesses and industry, the East Bay Regional Park District and the State Office of Emergency Services in order to test and improve preparedness capabilities.	The Project is consistent with this Policy. The Facility would be required to mitigate potential impacts by revising its emergency response plan, and developing Emergency Operating Procedures, for new and modified Project equipment. The revised Safety Plan would be submitted to CCHS for approval prior to Project operations. The Facility conducts annual emergency response drills in which off-site responding agencies such as the Richmond Fire Department and/or the CCHMP, the Chevron Fire Department, and non-responding employees work together to resolve a given scenario. This pre-planning activity is intended to ensure that the members of the responding agencies are familiar with the Facility, the hazards of the regulated substances, the resources available at the Facility, and the locations of these resources. After the commencement of Project operations, these drills would enable responding agencies to become familiar with Project equipment and operations to be better prepared to respond to an emergency involving Project facilities.	4.13 Public Safety
58. Action SN3.E: Corporation, Industry and Utility Emergency Plans Regularly meet with large employers to develop and maintain up-to-date emergency plans for use in the event of a catastrophic event.	The Project is consistent with this Action. The Project would be located within the existing Facility and would not introduce any hazardous substances not currently used and stored in larger quantities at the Facility so would not interfere with existing emergency plans for areas located outside of the Facility. The Project would be integrated into the Facility's emergency plan, described in <i>Section 4.13, Public Safety</i> . Therefore, there is nothing to suggest that the Project would in any way impair or interfere with this or other emergency plans; however, the Facility's emergency plan would be updated, as necessary, as part of revisions to its RMP and Safety Plan required by Contra Costa Health Services (CCHS). This update would mitigate any potential impact if done prior to operational commencement of the Project elements; therefore the Project is consistent with this Action.	4.13 Public Safety

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
59. Action SN4.A: Noise Study Report Requirement Require proposed commercial and industrial uses with potential noise and vibration-producing activities or new noise-sensitive uses that locate in an area with day-night average sound level of 55 or greater to provide noise study reports. The report should identify noise mitigation measures that limit noise to an acceptable level compared to existing conditions.	The Project is consistent with this Action. As described in <i>Section 4.11, Noise</i> , potential noise associated with the Project was studied to determine that modeled levels of concurrent operation of all construction equipment would comply with the strictest applicable noise standard identified in the Richmond Noise Ordinance. The Project also includes mitigation measures to ensure that any nighttime construction, should it occur, would comply with all applicable noise standards. In addition, modeling of noise associated with Refinery Operations after installation of the Project showed that the Project would not result in any increase in noise at the nearest residential receivers. Thus the Project is consistent with this Action.	4.11 Noise
XIV. HISTORIC RESOURCES ELEMENT		
60. GOAL HR1: Historic Resource Preservation Richmond has a rich history that is woven throughout the fabric of the community. Preserve historic resources and leverage them to enhance and build upon Richmond's historic character.	The Project is consistent with this Goal. There are no historic resources located within the Refinery Process and Tank Farm areas of the Facility, which have been developed for decades for Facility uses, nor would any historic resources be impacted by the Project or any Project Design Feature. As discussed in <i>Section 4.5, Cultural Resources</i> , there is one resource (P-07-3119) within the Facility, the Facility administration building that could qualify as an historic resource. At the time of this document's preparation, the City of Richmond was processing documentation to designate the Chevron administration building for local listing as a City of Richmond historic resource. If the structure is locally designated, the building would qualify as a historical resource under CEQA Guidelines Section 15064.5(a)(2). However, the building would not be impacted by the proposed Project as it is located outside the Refinery Process and Tank Farm areas and no construction is proposed in its vicinity. Most of the construction for the Project is already complete. The remaining construction would occur entirely within the previously disturbed Refinery Process Area Tank Farm areas of the Facility. These areas are highly industrialized and thus retain no architectural distinction, nor do the physical structures of the Facility appear to be associated with significant events or	4.5 Cultural Resources

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	persons in California's history. Therefore, the construction of the proposed facilities would not directly or indirectly result in a change to any historic resources. Construction and operation of the Project would not require the removal of historical structures or related demolition activities. As a result, the Project is consistent with this Policy of preserving historic resources.	
61. Policy HR1.1 Preservation of Diverse Resources Protect, preserve and enhance the diverse range of historic, cultural and archaeological sites and resources in the City for the benefit of current and future residents and visitors.	The Project is consistent with this Policy. There are no known unique or significant archeological resources at the Facility, nor were any discovered during the Project excavation and construction activities completed following issuance of the writ. The Project would not adversely change the significance of any unique archaeological resource. There are no subsurface construction activities associated with any Project Design Features, so Project Design Features would not cause any adverse change to the significance of any unique archeological resource. As a result, there would be no impacts to archeological resources due to the Project While the Facility is largely modified and disturbed, the vast majority of Project-related excavation and subsurface work has already been completed, remaining excavation work would occur only within previously-developed portions of the Facility, and there is no subsurface construction activity included in any Project Design Feature, the general Project vicinity has a considerable level of previously identified prehistoric sites, especially along the margins of the San Pablo Bay. Previously unknown archaeological sites, e.g., shell midden soils, lithic artifacts, historic trash scatters, may occur deeply buried within the Project site. Damage to significant buried archaeological deposits would be a significant adverse impact. The Project would implement Mitigation Measure 4.5-1, as described in <i>Section 4.5, Cultural Resources</i>, to ensure appropriate treatment of any prehistoric or historic subsurface cultural resources discovered during Project construction. As part of the Mitigation Monitoring and Reporting Program for the EIR, Chevron shall have environmental monitors on-site during construction of the	4.5 Cultural Resources

TABLE A4.10-1 CONSISTENCY EVALUATION OF RELEVANT GENERAL PLAN GOALS, POLICIES, AND ACTIONS

Richmond General Plan 2030 Goals, Policies, and Actions	Project Consistency Evaluation	EIR Organizational Note: Corresponding EIR Section Addressing Goal, Policy, Action
	Project. The construction workers shall be trained by the monitors on environmental sensitivity and the identification of prehistoric or historic subsurface cultural resources.	

APPENDIX 4.13

Public Safety

APPENDIX 4.13-DET

Public Safety Detailed Background

APPENDIX 4.13-DET

PUBLIC SAFETY DETAILED BACKGROUND

This appendix provides more detailed background information regarding current and emerging regulatory programs that serve to protect public safety, additional information about Chevron's current public safety programs, and Facility accident history, including agency findings regarding the August 6, 2012 fire.

1.1 REGULATORY SETTING

Petroleum refineries are subject to complex and often overlapping regulatory requirements regarding industrial safety under federal, State, and local laws. As discussed in *Section 4.13, Public Safety*, the regulations share common themes for prevention of, and appropriate response to, industrial process accidents, including: the protection of worker health and safety; reporting and disclosure; performance specifications; maintenance and inspections; and other related requirements.

Some regulatory programs based in air quality and public health also indirectly serve to protect public safety. Additional information on such programs, including current regulations and emerging regulatory initiatives, is provided below.

1.1.1 Current Regulations

1.1.1.1 Federal Requirements

1.1.1.1.1 *EPA National Emission Standards for Hazardous Air Pollutants Regulations (40 CFR Parts 61 and 63)*

As further discussed in *Appendix 4.3-REG* of this EIR, National Emission Standards for Hazardous Air Pollutants (NESHAPs) are stationary source requirements for hazardous air pollutants. Part 61 NESHAPs regulate seven hazardous air pollutants: asbestos; beryllium; mercury; vinyl chloride; benzene; arsenic; and radon/radionuclides. Part 63 NESHAPs were promulgated after the 1990 Clean Air Act Amendments, and require application of technology based emissions standards referred to as Maximum Achievable Control Technology (MACT). Consequently, these post-1990 NESHAPs are also referred to as MACT standards. The NESHAPs are delegated to the States, but both U.S. Environmental Protection Agency (EPA) and the States implement and enforce the NESHAP standards. The NESHAP program includes compliance monitoring of facilities subject to the regulations, which entails reviewing reports and records,

interviewing facility personnel knowledgeable of the facility, inspecting the processes with emissions points subject to standard sampling wastewater discharges if applicable, inspecting against design and work practice standards, and reviewing leak detection and repair methods. Additionally, sources subject to NESHAP regulations must perform an initial performance test to demonstrate compliance, and are normally required to demonstrate continued compliance. Local NESHAP requirements that apply to the Facility are established in Bay Area Air Quality Management District (BAAQMD) Regulation 11 (BAAQMD, 2014).

1.1.1.1.2 U.S. Department of Transportation Oil Spill Prevention and Response Plans (49 CFR Chapter I, Subchapter B, Part 130)

The Oil Transportation Regulations prescribe prevention, containment, and response planning requirements of the U.S. Department of Transportation (DOT) applicable to transportation of oil by motor vehicles and rolling stock (49 CFR Section 130.1). The requirements apply to any liquid petroleum oil in packaging having a capacity of 3,500 gallons or more, or any liquid petroleum or non-petroleum oil in a quantity greater than 42,000 gallons per packaging, subject to certain exceptions (49 CFR Section 130.2(a)). The requirements do not affect the DOT Hazardous Materials Regulations (40 CFR Subchapter C) (see below). The Oil Transportation Regulations include communication requirements (49 CFR Section 130.11), packaging requirements (49 CFR Section 130.21), and written response plan requirements (49 CFR Section 130.31).

1.1.1.1.3 DOT and Pipeline and Hazardous Materials Administration (PHMSA) - Hazardous Materials Regulations (HMR) (49 CFR Chapter I, Subchapter C, Part 171 et seq.)

The Hazardous Materials Transportation Act (HMTA), as amended (49 USC 5101 et seq.) authorizes the Secretary of the DOT to regulate the transportation of hazardous materials. The Secretary is authorized to issue regulations to implement statutory requirements. The Pipeline and Hazardous Materials Safety Administration (PHMSA) was delegated the responsibility to write the hazardous materials regulations (HMRs), which are contained in 49 CFR Chapter I, Subchapter C. 49 CFR Section 172.101 contains the list of hazardous materials regulated by DOT (referred to as the "Hazardous Materials Table", DOT PHMSA, 2013).

The HMRs are applicable to the transportation of hazardous materials in commerce and their offering to:

- Interstate, intrastate, and foreign carriers by rail car (49 CFR Part 174), aircraft (49 CFR Part 175), vessel (49 CFR Part 176), and public highway/motor vehicle (49 CFR Part 177).

- The representation that a hazardous material is present in a package, container, rail car, aircraft, motor vehicle or vessel.
- The manufacture, fabrication, marking, maintenance, reconditioning, repairing or testing of a package or container which is represented, marked, certified or sold for use in the transportation of hazardous materials (49 CFR 171.1(a)).

The HMRs include requirements for registration, carrier responsibility, incident reporting, communications, labeling, hazardous materials training, recordkeeping, security plans, packaging, and compatibility (DOT FMCSA, 2014).

1.1.1.1.4 DOT and PHMSA Pipeline Safety Regulations - Gas and Liquid Integrity Management Rules

The PHMSA, Office of Pipeline Safety (OPS) issues and enforces the Pipeline Safety Regulations (49 CFR Parts 190-199), implementing the Federal Pipeline Safety Law (49 USC Section 60101 et seq.), to ensure the safety of interstate and intrastate pipelines transporting hazardous liquids, natural gas, and other flammable, corrosive and toxic gases. States may enforce safety standards on intrastate pipelines if the State has been certified by PHMSA under 49 USC Section 60105.

- **Gas IM Rule (49 CFR Part 192) (Gas Transmission Integrity Management Program or "Gas IM Rule"):** Part 192 of the Pipeline Safety Regulations regulates the in-pipeline transportation of natural gas and other gases, including hydrogen, which is transported as a compressed flammable gas. In addition to regulating gathering and transmission, PHMSA regulates the distribution and storage of hydrogen gas by pipeline (49 CFR Section 192.3). The Gas IM Rule specifies how pipeline operators must identify, prioritize, assess, evaluate, repair, and validate the integrity of gas transmission pipelines that could, in the event of a leak or failure, affect High Consequence Areas (HCAs) (generally, areas with a certain number of buildings or occupied by a certain number of people for a minimum number of days per year) within the United States (49 CFR Section 192.903)(DOT PHMSA, 2014a).
- **Liquid IM Rule (40 CFR Part 195) (Liquid Pipeline Integrity Management Program or "Liquid IM Rule"):** The Liquid IM Rule specifies how pipeline operators must identify, assess, evaluate, repair, and validate the integrity of hazardous liquid pipelines that could, in the event of a leak or failure, affect High Consequence Areas (HCAs), which include: commercially navigable waterways; high population or urbanized areas with at least 50,000 or more people and a population density of at least 1,000 people per square mile; a populated area that contains a concentrated population such as an

incorporated or unincorporated city, town, village, or other designated residential or commercial area; or an unusually sensitive area (drinking water or ecological resource area that is unusually sensitive to environmental damage from a hazardous liquid pipeline release) (49 CFR Section 195.450) (DOT PHMSA, 2014b).

1.1.1.1.5 Marine Protection, Research and Sanctuaries Act of 1972 (16 USC Section 1431 and 33 USC Section 1401) (MPRSA)

The Marine Protection, Research, and Sanctuaries Act (MPRSA) (also referred to as the Ocean Dumping Act) implements the London Convention, an international treaty that governs ocean dumping. The MPRSA prohibits dumping material into the ocean that would unreasonably degrade or endanger human health or the marine environment. Specifically, the MPRSA generally prohibits (1) transportation of material from the United States for the purpose of ocean dumping; (2) transportation of material from anywhere for the purpose of ocean dumping by U.S. agencies or U.S.-flagged vessels; (3) dumping of material transported from outside the United States into the U.S. territorial sea. A permit is required to deviate from these prohibitions. The standard for permit issuance is whether the dumping will "unreasonably degrade or endanger" human health, welfare, or the marine environment. Criteria and procedures for ocean dumping permits are established in EPA's ocean dumping regulations (40 CFR Parts 220-229).

1.1.1.1.6 Facility Security Rule (33 CFR Part 105)

The U.S. Coast Guard oversees development and implementation of security measures at marine oil terminals, and on oil tankers. Vessels and facilities must conduct security assessments, and must submit a Vessel Security Plan (VSP) or Facility Security Plan (FSP) to the Coast Guard for approval.

1.1.1.1.7 Chemical Facilities Anti-Terrorism Standards (CFATS) Regulation (6 CFR Part 27)

The U.S. Department of Homeland Security promulgated the Chemical Facilities Anti-Terrorism Standards (CFATS) regulations as a comprehensive federal security program for high-risk chemical facilities. The rule establishes risk-based performance standards, requiring covered facilities to prepare Security Vulnerability Assessments and to develop and implement Site Security Plans. Facilities are assigned to one of four risk tiers, based on potential consequences and likelihood of an attack on the facility. Based on the risk tier classification, facilities are subject to varying performance and planning requirements.

1.1.1.2 State Requirements

1.1.1.2.1 *California Aboveground Petroleum Storage Act (APSA) (Cal. H&S Code Sections 25270 et seq.)*

The California Aboveground Petroleum Storage Act (APSA) regulates above-ground storage of petroleum and petroleum products. A tank facility¹ is subject to the APSA if: (1) the tank facility is subject to the federal oil pollution prevention regulations (40 CCR Part 112); or (2) the tank facility has a storage capacity of 1,320 gallons or more of petroleum (Cal. H&S Code Section 25270.3).

The owner of a facility subject to the APSA must prepare a Spill Prevention Control and Countermeasure (SPCC) plan in accordance with the federal oil pollution prevention program (40 CCR Part 112), and must conduct period inspections to assure compliance with Section 112, subject to certain exceptions (Cal. H&S Code Section 25270.4.5).

The Certified Unified Program Agency (CUPA) implements the APSA (Cal. H&S Code Section 25270.4). At least once every three years, the CUPA conducts inspections of each storage tank or a representative sampling of storage tanks at each tank facility with aggregate storage capacity of 10,000 gallons or more of petroleum. The purpose of the inspection is to determine whether the owner or operator is in compliance with the spill prevention control and countermeasure plan requirements of the APSA (Cal. H&S Code Section 25270.5(a)).

1.1.1.2.2 *California Underground Storage Tank Program (Cal. H&S Code Sections 25280 et seq.; 23 CCR Division 3, Chapter 16)*

The Underground Storage Tank (UST) Program is intended to protect public health and safety and the environment from releases of petroleum and other hazardous substances from USTs.² There are four program elements: (1) leak prevention; (2) cleanup; (3) enforcement; and (4) tank tester licensing. The CUPA

¹ "Tank facility" means one or more aboveground storage tanks, including any piping that is integral to the tanks, that contain petroleum and that are used by an owner or operator at a single location or site. For purposes of this section, a pipe is integrally related to an aboveground storage tank if the pipe is connected to the tank and meets any of the following: (1) the pipe is within the dike or containment area, (2) the pipe is between the containment area and the first flange or valve outside the containment area, (3) the pipe is connected to the first flange or valve on the exterior of the tank, if state or federal law does not require a containment area, and (4) the pipe is connected to a tank in an underground area (Cal. H&S Code Section 25270.2(n)).

² "Underground storage tank" is defined as any one or combination of tanks, including pipes connected thereto, that is used for the storage of hazardous substances and that is substantially or totally beneath the surface of the ground (Cal. H&S Code Section 25281(y)(1)).

is the implementing agency for the leak prevention program element (Cal. H&S Code Section 25283(a))(SWRB, 2013).

1.1.1.2.3 California Highway Patrol Hazardous Materials Transportation (13 CCR., Div 2, Chapter 6)

The California Highway Patrol (CHP) has adopted regulations governing the transportation of hazardous materials on California roads and highways (13 CCR Division 2 Chapter 6) (see also federal hazardous materials safety regulations at 49 CFR Parts 171-180). These regulations apply to shipments of hazardous materials to and from the Facility and conform with federal DOT requirements. These regulations contain extensive requirements regarding packaging, labeling, placarding, record-keeping, release reporting and insurance.

1.1.1.2.4 California Pipeline Safety Act (GOV Code Sections 51010 et seq.) (24 CCR Part 9 Section 1.11.1 et seq.)

The State Fire Marshal (SFM) has exclusive safety, regulatory, and enforcement authority over interstate hazardous liquid pipelines, and may act as agent for the U.S. Secretary of Transportation to implement the federal Hazardous Liquid Pipeline Safety Act (49 USC Sections 2001 et seq.) and federal pipeline safety regulations as to those portions of interstate pipelines located within the state, as necessary to obtain annual federal certification (GOV Code Section 51010). Certain pipelines at the Facility are regulated under this program. Key elements to pipeline safety include routine maintenance, pigging (line clearing), line inspections, written procedures, and regular training. Covered pipelines must undergo periodic integrity testing using procedures approved by the SFM staff. In addition, all regulated pipelines are subject to inspection and testing by the SFM staff, with attention to corrosion, maintenance of proper operating pressures and electrical isolation. All spills, ruptures, fires and similar incidents must be reported and investigated for cause.

1.1.1.2.5 Porter-Cologne Water Quality Control Act Section 13272

Any person who, without regard to intent or negligence, causes or permits any oil or petroleum product to be discharged in or on any waters of the state, or discharged or deposited where it is, or probably will be, discharged in or on any waters of the state, shall as soon as (1) that person has knowledge of the discharge, (2) notification is possible, and (3) notification can be provided without substantially impeding cleanup or other emergency measures, immediately notify the California Emergency Management Agency of the discharge in accordance with the spill reporting provision of the California oil spill contingency plan (California Water Code Section 13272(a)). The reportable quantity for oil or petroleum products shall be one barrel (42 gallons) or more, by direct discharge to the receiving waters, unless a more restrictive reporting

standard for a particular body of water is adopted (California Water Code Section 13272(f)). The State Water Resources Control Board and Regional Water Quality Control Board (RWQCB) manage this and other statutory programs designed to prevent and minimize potentially harmful discharges of hazardous materials into surface waters and groundwater. These agencies, and these water quality protection mandates, are discussed in greater detail in *Section 4.9, Hydrology and Water Quality*.

1.1.1.2.6 Lempert-Keene-Seastrand Oil Spill Prevention and Response Act of 1990 (GOV Code Section 8670.1 et seq.)

The statute requires the Governor to appoint an administrator for oil response, who must be a deputy director of the California Department of Fish and Wildlife (CDFW) (GOV Code Section 8670.4). The administrator, subject to the Governor, has the primary authority to direct prevention, removal, abatement, response, containment, and cleanup efforts with regard to all aspects of any oil spill in the marine waters of the state, in accordance with any applicable marine facility or vessel contingency plan and the California oil spill contingency plan. The administrator shall cooperate with any federal on-scene coordinator, as specified in the National Contingency Plan (GOV Code Section 8670.7(a)). The administrator has additional duties related to oil spill clean-up and response (GOV Code Sections 8670.6 - 8670.14).

The statute establishes requirements for oil spill response, including the duty to clean up and remove the oil and to comply with the applicable oil spill contingency plan, and to immediately report the discharge to the California Emergency Management Agency (GOV Code Sections 8670.25 - 8670.27).

The statute also establishes requirements for oil spill contingency planning, including preparation of administrator-approved contingency plans for marine facilities and vessels, and screening and comprehensive risk-based monitoring for inspecting vessels at anchor and alongside docks (GOV Code Sections 8670.28 - 8670.37.5).

1.1.1.2.7 California Department of Fish and Wildlife Office of Spill Prevention and Response (OSPR) Oil Spill Investigation

The Office of Spill Prevention and Response (OSPR) mission is to provide best achievable protection of California's natural resources by preventing, preparing for, and responding to spills of oil and other deleterious materials, and through restoring and enhancing affected resources. OSPR and the U.S. Coast Guard jointly prepared oil spill contingency plans for California port areas, including the Port of San Francisco. The San Francisco Oil Spill Contingency Plan (CDFW, 2013b) is available online. The Lempert-Keene-Seastrand Oil Spill Prevention and

Response Act of 1990 (SB 2040) details the role of the OSPR in spill investigations. OSPR is the lead investigative unit for state and local governments. As the lead agency, OSPR will coordinate the investigative efforts for these government agencies (Contingency Plan, Section 1000) (CDFW, 2013a).

1.1.1.2.8 California State Lands Commission, Marine Facilities Division Marine Oil Terminal Engineering and Maintenance Standards

The Marine Oil Terminal Engineering and Maintenance Standards (MOTEMS) were approved by the California Building Standards Commission (BSC) on January 19, 2005, and codified as the 2001 Title 24, California Code of Regulations, Part 2, California Building Code, Chapter 31F - Marine Oil Terminals. These standards apply to all existing and new marine oil terminals in California, and include criteria for inspection, structural analysis and design, mooring and berthing, geotechnical considerations, fire, piping, mechanical and electrical systems.

1.1.1.3 Regional and Local Requirements

1.1.1.3.1 BAAQMD Regulations and Permit Requirements

Appendix 4.3-REG of this EIR describes BAAQMD regulations and permit requirements applicable to the Facility. These regulations establish comprehensive permitting programs for new and modified sources, as well as substantive standards that apply to many aspects of refining operations, e.g., leak detection and repair, storage of organic compounds, flaring, emissions of organic compounds, and control of hazardous air pollutants. Repair/replacement of emitting equipment at the Facility must be evaluated for consistency with BAAQMD permit requirements. Breakdowns and other incidents resulting in violation of applicable regulations must be promptly reported. Flaring events must be reported and investigated, and a report on the primary cause of the flaring event must be submitted to BAAQMD. Several BAAQMD regulations of particular relevance to public safety are as follows:

- **Regulation 1 (General Provisions):** Regulation 1, Section 301 establishes BAAQMD's standard for public nuisance. This rule prohibits discharges of air contaminants which cause injury, detriment, nuisance, or annoyance to any considerable number of persons or the public, or which endangers the comfort, repose, health or safety of any such persons or the public, or which may cause injury or damage to business or property (BAAQMD, 2011).
- **Regulation 2-5 (New Source Review):** Regulation 2-5 applies preconstruction permit review to new and modified sources of toxic air contaminants, and it contains project health risk limits and requirements for Toxics Best Available Control Technology (BAAQMD, 2010).

- **Regulation 8-40 (Aeration of Contaminated Soil and Removal of Underground Storage Tanks):** Regulation 8-40 limits the emission of organic compounds from soil that has been contaminated by organic chemical or petroleum chemical leaks or spills (BAAQMD, 2005).
- **Regulation 11 (Hazardous Pollutants):** sets emissions and/or performance standards for certain hazardous pollutants including asbestos containing materials (ACM), lead, and benzene (BAAQMD, 2014).
- **Regulation 12, Rule 11 (Flare Monitoring at Petroleum Refineries):** requires monitoring and recording of emission data for flares at petroleum refineries. It requires operators of flares at petroleum refineries to monitor the gases directed to the flare and submit a monthly report containing:
 - The total daily and monthly volumetric flow of the vent, pilot, and purge gas;
 - The hourly average molecular weight of the vent gas;
 - Composition of vent gas from required sampling;
 - Calculated daily and monthly methane, non-methane and SO₂ emissions; and
 - Archive images of the flare (BAAQMD, 2003).
- **Regulation 12, Rule 12 (Flares at Petroleum Refineries)** is intended to reduce emissions from flares at petroleum refineries by minimizing the frequency and magnitude of flaring. Flaring is prohibited unless consistent with an approved Flare Minimization Plan (Flare MP) that includes: (1) a detailed description and technical information for each flare; (2) a description of the equipment or procedures implemented within the last five years or planned to reduce flaring; and (3) a description of prevention measures needed to perform certain refinery activities without flaring. Each refinery must submit a Flare MP Annual Update no more than 12 months following approval of the initial Flare MP, and annually thereafter. Each refinery's Flare MP Annual Update must include any new prevention measures identified as a result of an investigation into the cause of flaring events that have occurred since the previous Flare MP approval. The plan updates (with the exception of confidential information) are required to be made available to the public during a 30-day public review and comment period. A Flare MP Annual Update will be approved only after consideration of public comments, and if the District determines that all feasible prevention measures have been incorporated and, if not already undertaken, scheduled for expeditious implementation (BAAQMD, 2006).

1.1.1.3.2 *City of Richmond Zoning Ordinance*

The Richmond Zoning Ordinance is contained in Chapter 15.04 of the Richmond Municipal Code. The Zoning Ordinance contains three types of zoning regulations that control the use and development of property: (1) land use regulations that specify land uses permitted or conditionally permitted in each zoning district, and include special requirements, if any, applicable to specific uses; (2) development regulations that control the height, bulk, location, and appearance of structures on development sites; and (3) administrative regulations that contain detailed procedures for the administration of zoning regulations (Richmond Municipal Code (RMC) Section 15.04.010(B)). The Planning Director and/or the Assistant City Engineer, building regulations division have a duty to enforce the Zoning Ordinance (RMC Section 15.04.950.030).

Zoning Ordinance provisions designed to promote the public health, safety, and welfare include the following:

- **M-3 Zoning District; Conditional Use Approval:** The Modernization Project is located in the M-3 Zoning District. Petroleum refining and related industries are a conditional use within the M-3 Zoning District. Therefore, the Modernization Project may be permitted by conditional use permit and then must comply with the terms and conditions of the permit (RMC Section 15.04.330.040). The Planning Commission has authority to impose reasonable conditions on the conditional use application to protect the public health, safety, and welfare of the citizens of the City of Richmond and to ensure that the operation and maintenance of the conditional use will be compatible with the neighborhood where it will be located (RMC Section 15.04.910.050(B)).
- **Design Review Approval:** The Modernization Project requires design review approval. The Design Review Board (DRB) reviews the design of exterior construction or modifications for which discretionary planning approval is required (RMC Section 15.04.930.020(A)). Applications requiring both Planning Commission and DRB approval are reviewed by the DRB for recommendation to the Planning Commission (*Id*). The DRB has authority to impose reasonable conditions in order to promote the public health, safety, and welfare of the citizens of the City of Richmond, and to that the design of the Modernization Project will be compatible with the area surrounding where it will be located (RMC Section 15.04.930.110(B)).
- **Hazardous Materials Ordinance:** Additionally, the Zoning Ordinance includes hazardous materials provisions (RMC Section 15.04.820.020) that govern all projects and activities which involve hazardous waste or hazardous materials (RMC Section 15.04.820.021). The purpose of the Hazardous

Materials Ordinance is to establish a basis for the issuance of conditional use permits for projects and activities that could significantly and/or adversely affect public health or the environment, and that generate, store, transport, treat, or dispose of significant amounts of hazardous materials. Further, the intent is to encourage reductions in the amounts of hazardous wastes or materials managed for the benefit of the health, safety, and general welfare of the residents and persons within the City of Richmond. Conditional use applications subject to the Hazardous Materials Ordinance must include certain information and require specific findings for approval (RMC Section 15.04.820.024(A) - (B)).

1.1.1.4 Industry Standards and Best Management Practices

In addition to the California Building Code (CBC) and incorporated standards, the Facility is also subject to the State Safety Orders (California Code of Regulations, Title 8), which in some cases incorporates industry standards for operation and maintenance of refineries, including inspections. For example, the CBC (24 CCR Part 2) adopts as standard reference documents certain codes, standards, and publications adopted and set forth in the code (CBC, Section 1.1.5; Chapter 34 (Referenced Standards)). The California Fire Code (CFC) (24 CCR Part 9) similarly provides that the codes and standards referenced in the CFC are considered part of the requirements of the CFC, to the extent prescribed by each reference (CFC, Section 1.1.5, 102.7, 105.2.4; Chapter 47 (Referenced Standards)). The discussion below provides a brief description of the most relevant industry standards routinely used at the Facility and some relevant industrial references used to assess process safety and impact from industrial releases.

1.1.1.4.1 *American Petroleum Institute Standards*

The American Petroleum Institute (API) promulgates standards for use throughout various sectors of the petroleum industry. The API's Standards Committees consist of subcommittees and task groups made up of industry experts who develop API standards. These groups identify the need for standards, then develop, approve, and revise those standards and other technical publications. The standards-writing subcommittees and task groups are open to representatives of groups that are materially affected by the standards. These include oil and gas companies, manufacturers and suppliers, contractors and consultants, and representatives of government agencies and academia.

The API Committee on Facility Equipment works to promulgate safe and proven engineering practices for the design, fabrication, installation, inspection, and use of materials and equipment in refineries and related processing facilities. These practices are produced in accordance with the API Procedures for Standards

Development and published as API Standards, Specifications and Recommended Practices. Below is a list of the subcommittees and the areas they work with:

- Subcommittee on Corrosion & Materials
- Subcommittee on Electrical Equipment
- Subcommittee on Heat Transfer Equipment
- Subcommittee on Inspection
- Subcommittee on Instruments & Control Systems
- Subcommittee on Mechanical Equipment
- Subcommittee on Piping & Valves
- Subcommittee on Pressure-Relieving Systems
- Subcommittee on Aboveground Storage Tanks

An illustrative listing and description of API Standards applicable to refining can be found online (API, 2014). While many of these standards are unique to certain types of operations or conditions, not all of which are applicable to the Facility, certain standards are applied regularly, including numerous standards that have been adopted as part of the State’s Occupational Safety and Health Administration (Cal/OSHA) Process Safety management (PSM) regulations and compliance with which is a function of Cal/OSHA’s regulatory oversight of the Facility, as indicated in Table A4.13-DET-1.

TABLE A4.13-DET-1 API STANDARDS ADOPTED BY CAL/OSHA

API Standard	Description	Adopted as Regulation	Associated Regulation
API- 510	Pressure Vessel Inspection Code	Yes	State of California State Safety Orders Title 8: Article 18 Subchapter 15. Petroleum Safety Orders--Refining, Transportation and Handling Article 18. Unfired Pressure Vessels, Boilers, and Fired Pressure Vessels and Pressure Relief Valves §6857. Vessels, Boilers and Pressure Relief Devices.
API-570	Piping Inspection Code	Yes	State of California State Safety Orders Title 8: Article 146 Subchapter 15. Petroleum Safety Orders--Refining, Transportation and Handling Article 16. Pumps, Pipe Lines and Valves §6845. Piping, Fittings, and Valves

API Standard	Description	Adopted as Regulation	Associated Regulation
API-579	Fitness-for-Service	Yes	State of California State Safety Orders Title 8: Article 18 Subchapter 15. Petroleum Safety Orders--Refining, Transportation and Handling Article 18. Unfired Pressure Vessels, Boilers, and Fired Pressure Vessels and Pressure Relief Valves §6857. Vessels, Boilers and Pressure Relief Devices.

Other API standards that are regularly applied at the Facility are shown in Table A4.13-DET-2.

TABLE A4.13-DET-2 API STANDARDS REGULARLY APPLIED AT THE FACILITY

API Standard	Description
API-500	Recommended Practice for Classification of Locations for Electrical Installations at Petroleum Facilities Classified as Class I, Division 1 and Division 2
API-520	Sizing, Selection and Installation of Pressure-Refining Devices in Refineries, Part I - Sizing and Selection, 7 th ed. 2000
API-521	Guide for Pressure-Relieving and Depressuring Systems, 2 nd ed. 1982 - 4 th ed. 1997
API-571	Damage Mechanisms Affecting Equipment in Refining Industry
API-572	Inspection of Pressure Vessels
API-573	Inspection of Fired Heater and Boilers
API-574	Inspection Practices for Piping System Components
API-578	Positive Material Identification
API-580	Risk-based Inspection
API-653	Tank Inspection, Repair, Alteration and Reconstruction
API-RP 752	Management of Hazards Associated with Location of Process Plant Buildings 3 rd ed. 2009
API-RP 753	Management of Hazards Associated with Location of Process Plant Portable Buildings 1 st ed. 2007
API-RP 754	Process Safety Performance Indicators for the Refining and Petrochemical Industries 1 st ed. 2010
API-RP 755	Fatigue Prevention Guidelines for the Refining and Petrochemical Industries
API-932B	Design, Materials, Fabrication, Operation, And Inspection

API Standard	Description
	Guidelines For Corrosion Control In Hydroprocessing Reactor Effluent Air Cooler (reac) Systems
API-939-c	Guidelines for Avoiding Sulfidation (Sulfidic) Corrosion Failures in Oil Refineries
API-941	High Temperature Hydrogen Attack
API-945	Avoiding Amine Stress Corrosion Cracking

Source: Chevron Data Transmittal #91, 2014.

In addition, Chevron Corporation, through its Energy Technology Company (ETC), specifically the Technical Codes & Standards (TC&S) group, develops, maintains, and publishes for proprietary use the Chevron Engineering Standards (CES). CES serve as the structured corporate library of engineering specifications, drawings, data sheets, and guidelines that constitute the company's repository of Chevron's collective knowledge for engineering facilities. The TC&S team is charged with CES's organization, accessibility, renewal, and optimization procedures. The CES are developed by Technology Subject Matter Experts (SMEs) using official codes, as well as industry, association, and Chevron-specific guidelines/recommendations which, in some cases, are more stringent than generally accepted ones. These codes and standards are for new facility design, construction, commissioning, start-up, operations, maintenance, and decommissioning. Further, as part of their process safety management system, existing facilities undertake a fitness-for-service analysis using their Integrity/Reliability and Health, Environment, and Safety (HES) Risk Management processes to identify the technical codes and standards that were applied during the design and construction of existing equipment, and determine and document any modifications that may be necessary for the equipment to be determined fit-for-service.

1.1.1.4.2 *National Fire Prevention Association (NFPA)*

The National Fire Prevention Association (NFPA) is an international nonprofit organization that works to reduce the burden of fire and other hazards on the quality of life by providing and advocating consensus codes and standards, research, training, and education. NFPA develops, publishes, and disseminates more than 300 consensus codes and standards intended to minimize the possibility and effects of fire and other risks, such as NFPA 30 Flammable and Combustible Liquids Code.

1.1.1.4.3 *American Institute of Chemical Engineers*

American Institute of Chemical Engineers (AIChE) is a nonprofit organization for the chemical engineering profession representing 45,000 members in industry,

academia, and government, which provides support and technical information to members. The Center for Chemical Process Safety (CCPS), a not-for-profit, corporate membership organization within the AIChE, has published numerous illustrative process safety reference materials useful for assessing potential accidents and their impacts (written by technical committees of experts in process safety that are peer reviewed) regarding refining and other high-hazard industries, including the following:

- Guidelines for Developing Quantitative Safety Risk Criteria (CCPS, 2009a)
- Guidelines for Process Safety Metrics (CCPS, 2009b)
- Guidelines for Enabling Conditions and Conditional Modifiers in Layers of Protection Analysis (LOPA) (CCPS, 2013)
- Guidelines for Evaluating the Characteristics of Vapor Cloud Explosions, Flash Fires, and Boiling Liquid Vapor Cloud Explosions (BLEVEs; CCPS, 2010)
- Guidelines for Hazard Evaluation Procedures (CCPS, 2008a)
- Guidelines for the Management of Change for Process Safety (CCPS, 2008b)
- Human Factors Methods for Improving Performance in the Process Industries (CCPS, 2006)
- Guidelines for Hazard Evaluation Procedures (CCPS, 2008a)
- Guidelines for Risk Based Process Safety (CCPS, 2007)
- Guidelines for Integrating Process Safety into Engineering Projects (CCPS, 2014)

1.1.1.4.4 *American Industrial Hygiene Association (AIHA)*

The American Industrial Hygiene Association (AIHA) is a nonprofit organization with approximately 10,000 members that serves the needs of occupational and environmental health and safety professionals practicing industrial hygiene in industry, government, labor, academic institutions, and independent organizations. AIHA promotes certification of industrial hygienists, administers comprehensive education programs, and operates several laboratory accreditation programs.

- **Emergency Response Planning Guidelines (ERPGs):** AIHA's Emergency Response Planning Committee developed the ERPGs for responding to potential releases of airborne substances for use in community emergency planning. The Valero Improvement Modernization Project DEIR states that ERPGs are generally the most applicable standards on toxic gas exposure and effects (ESA, 2002). ERPGs are intended to provide estimates of threshold

concentration of acutely hazardous substances where a range of adverse effects might occur depending on the severity of the effect, and for use as tools to assess the adequacy of accident prevention and emergency response plans (ERPs), including transportation emergency planning, community ERPs, and incident prevention and mitigation (ESA, 2002).

1.1.2 Emerging Policy Initiatives

1.1.2.1 CARB Initiatives

The California Air Resources Board (CARB) and the California Air Pollution Control Officers Association (CAPCOA) released a plan on July 19, 2013 entitled *Air Monitoring for Accidental Refinery Releases: Assessment of Capabilities and Potential Improvements Project Plan* in support of the mission of the Governor's Interagency Working Group on Refinery Safety (CARB and CAPCOA, 2013). The plan lays out the process and timeline for assessing and improving California's current refinery air monitoring and emergency response system. The 15-month project will be conducted collaboratively with local air monitoring agencies, and will evaluate and make recommendations on the potential need for additional resources, including equipment, services, staffing, and training to support local air emergency response programs.

CARB is building a new publicly accessible website as a state clearinghouse for refinery air monitoring data and real-time information. The website will include air quality monitoring data from local air districts' current air monitors, and includes new monitors recently installed near the Facility (CARB, 2014; COR, 2013).

1.1.2.2 BAAQMD

BAAQMD is developing a new rule to expand refinery monitoring and emissions tracking. Draft Proposed Regulation 12, Rule 15 (Petroleum Refining Emissions Tracking) would require refineries to prepare refinery-wide emissions inventories on an annual basis, and develop and implement an emissions reduction plan if emissions exceed specified trigger-levels compared to the Facility's baseline inventory (BAAQMD, 2013). If an emissions reduction plan fails to identify measures that can reduce emissions to a level that is lower than the trigger levels, then an emissions reduction audit is required. In addition, each refinery will be required to prepare and submit an air monitoring plan detailing fence line and community air monitoring systems, and to operate and maintain these systems. BAAQMD anticipates the final rule will be adopted in the first half of 2014.

1.1.2.3 Other Stakeholders

Other stakeholders have also reviewed and recommended changes to the existing regulatory programs and industry standards and practices governing refinery safety that were consulted in the public safety analysis presented in this chapter, including:

- The federal Chemical Safety Board (CSB) has been asked by its staff to consider recommending a new regulatory paradigm for managing safety risks. The CSB has identified weaknesses in both federal and California safety regulatory regimes, and has been asked by staff to evaluate whether a regulatory regime similar to the European "safety case" framework would be more effective at ensuring safety at high hazard facilities such as petroleum refineries (CSB, 2013b). CSB issued a draft report in December 2013 (CSB, 2013a) elaborating on the safety case regulatory regime. The CSB Board has not approved the report, and has directed further staff investigation on the safety case framework. CSB staff recommendations have included:
 - Enhancing Occupational Safety and Health Administration (OSHA) and Cal/OSHA PSM regulations to require periodic corrosion reviews and effective risk reduction;
 - Establish effective mechanisms for regulators to require improvements to recognized industry standards so that they establish needed process safety or integrity requirements, compared to the present system under which regulations recognize industry standards that contain "should" and "consider" statements instead of mandatory requirements;
 - Revise State and local process safety regulations regarding incident investigation to require rigorous post-incident hazard reviews or mandate inherently safer technology, such as corrosion resistant piping materials. Currently, both inherently safer technology and as low as reasonably possible (ALARP) principles remain voluntary instead of mandatory;
 - Revise state and local process safety regulations to mandate "effective" management of change (MOC) reviews, rather than merely conducting them and implementing agreed upon actions that may not effectively reduce risks;
 - Revise process safety regulations to require facilities to report to OSHA/Cal/OSHA when their use of highly hazardous chemicals in large quantities meets the standards' provisions for coverage;
 - Revise process safety regulations to expand coverage to chemicals that can undergo a catastrophic runaway reaction, rather than the the currently limited coverage to flammable, explosive, and toxic chemicals;

- Revise process safety regulations to incorporate leading and lagging process safety metrics, and to incorporate safe siting guidelines;
- Cal/OSHA should increase process safety staffing with expanded technical qualifications; and
- Cal/OSHA should conduct frequent audits of major hazard facilities and use company-reported leading and lagging process safety indicators to focus the audits.

Some parties, including the former chair of CSB and other safety professionals, have objected to the adoption of the new "safety case" regulatory paradigm. This recommendation remains pending with CSB.

- University of California School of Public Health's Labor Occupational Health Program (LOHP) (operating under the aegis of the Center for Occupational and Environmental Health), recently completed a Summary Report to Governor Brown's Interagency Task Force on Refinery Safety, which included recommendations for safety program reforms compiled by representatives from labor and community groups, as well as fire protection agencies (Wilson, 2013). The LOHP Report identified 19 specific changes that should be made to the existing regulatory framework for refinery safety. The response of the Governor's Interagency Task Force to the LOHP Report has not yet been issued but the LOHP Report was summarized in the California Environmental Protection Agency (Cal/EPA) Interagency Refinery Task Force's February 2014 report (Cal/EPA, 2014) discussed in *Section 4.13.2.3.5.2, California Interagency Working Group on Refinery Safety and Interagency Refinery Task Force*.
- The RAND Corporation, a nonprofit institution focused on improving policy and decision making through research and analysis, was asked by the Governor's Interagency Task Force on Refinery Safety to investigate several issues to inform the Task Force's discussions. In response to this request, RAND published a memorandum, *Refinery Process Safety Performance and Models of Government-Industry Relations* (RAND, 2013) which:
(1) summarizes information about different regulatory models and provides some recommendations about how to proceed in adopting new models; (2) summarizes suggestions about the role "leading indicators" can play in future regulation; and (3) reviews what existing measures indicate about changes over time and comparisons across continents. Accordingly, the RAND Corporation recommended that: (1) more responsibility be placed on refineries to lay out how they will ensure safety, and have regulators audit

their performance; and (2) an incremental approach for making a transition from the current enforcement program to the one recommended be adopted.

- The United Steelworkers (USW), the largest labor organization representing refinery workers, developed a Triangle of Prevention (TOP) safety program that increases the role of workers in preventing, reporting, and responding to accidents and "near miss" situations (McQuiston et al., 2012).
- The USW issued a report with recommendations for improving refinery safety in connection with the BP Texas City catastrophe in 2005. The report "*Beyond Texas City: The State of Process Safety in the Unionized U.S. Oil Refining Industry*" (USW, 2007), calls on the refining industry to initiate ten essential actions.
- Following the BP Texas City fire in 2005, and based on the recommendation of the CSB, an independent panel of experts led by former U.S. Secretary of State, James Baker, conducted a comprehensive review of BPs safety practices and published a report with ten detailed recommendations that may serve as a best-practice reference guide for any refinery seeking to strengthen its safety programs (Baker et al., 2007).

While several of the recommendations identified in the proposed California legislation, regulatory agency initiatives, proposed changes to industry standards and recommended practices, recommendations included in the CSB report and the UC Report, and the components of the USW TOP program go beyond California Environmental Quality Act (CEQA) mitigation for impacts relating to potential public safety risks from the sulfur-related components of the Modernization Project or the increased Facility utilization, collectively these proposals were considered in this public safety impact analysis.

1.1.3 Community Health and Safety, including Environmental Justice Considerations

As discussed and analyzed in greater detail in *Section 4.3, Air Quality*, federal, State, and local law and policy in recent years have sought to address "environmental justice" – the fair treatment of people of all races, income levels, and cultures with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies (GOV, Section 65040.12(c)).

A 1994 federal Executive Order directed federal agencies to identify and address areas with disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low-income populations (FR, 1994). The California Attorney General has indicated that

“identifying [disadvantaged and minority] communities is an essential part of describing the relevant CEQA setting.”

BAAQMD has established the Community Air Risk Evaluation (CARE) program to evaluate and reduce health risks associated with exposures to outdoor toxic air contaminants (TACs) in the Bay Area. As part of the CARE program, BAAQMD developed a methodology for identifying communities within the San Francisco Bay Area that are likely to face the highest health risks from TACs, based on identifying areas that (1) are close to or within areas of high TAC emissions; (2) have sensitive populations, defined as youth and seniors, with significant TAC exposures; and (3) have significant poverty. BAAQMD included the City of Richmond as one of six high priority communities, based on its analysis of conditions. Additional information on the CARE program is provided in *Appendix 4.3-PHYS*.

1.2 CHEVRON SAFETY PROGRAM

The text in this section was provided by Chevron, and provides more detailed information on Chevron's existing safety programs, including details on the Facility's process safety management program. Review of these Chevron programs, scores of hours of meetings and document review, and Facility visits were all integral parts of the review and EIR preparation process completed by the City's independent safety experts.

1.2.1 Process Safety Management

While the statutory basis and general purpose of the Cal/OSHA requirements (the State has delegated authority from Federal OSHA [29 USC Section 667]) are discussed in *Section 4.13 Public Safety*, these detailed requirements serve a significant purpose and warrant more detailed discussion in this appendix. The requirements of the PSM rules are directed primarily at protecting workers within the Facility, and particularly in the context of preventing and mitigating the consequences of accidental releases of hazardous substances used in a process.³ Given that workers are the first to be exposed to a hazard, standards that minimize risks to workers often serve to indirectly minimize risks to the public as well.

³ A “process” is defined as: “any activity involving a highly hazardous chemical including any use, storage, manufacturing, handling, or the on-site movement of such chemicals, or combination of these activities. For purposes of this definition, any group of vessels which are interconnected and separate vessels which are located such that a highly hazardous chemical could be involved in a potential release shall be considered a single process” (29 C.F.R. 1910.119(b)).

The PSM standard applies to facilities with processes involving any of more than 130 listed hazardous chemicals at or above specified threshold quantities, including four chemicals that are present at the Facility at or above the PSM threshold quantities (Chevron Data Transmittal #87, 2014). The PSM standard establishes a comprehensive management program, integrating technologies, procedures, and management practices. The PSM standard consists of provisions addressing process safety information (PSI), process hazard analysis (PHA), operating procedures, training, contractors, pre-startup safety review (PSSR), mechanical integrity, hot work permits, MOC, incident investigations, emergency planning and response, employee participation, and compliance safety audits. The following summarizes the implementation of the Facility's PSM Program with reference to elements that also satisfy California Accidental Release Prevention (Cal/ARP) Program requirements.

1.2.1.1 Process Safety Information

The PSM standard requires that an employer compile PSI before conducting PHA, to enable persons involved in the process to identify and understand the hazards posed by those processes. PSI includes information pertaining to the hazards of the highly hazardous chemicals used or produced by the process, information pertaining to the technology of the process, and information pertaining to the equipment in the process. The development, dissemination, and use of PSI are vital to the effective operation of the Chevron Richmond Facility. Personnel use information regarding chemical hazards, equipment specifications, and operating limits in daily operation and strategic decision making. The Facility's PSI program is also designed to satisfy the requirements of Section 2760.1 of the Cal/ARP regulations.

The Facility compiles PSI during the design and construction of a process. The PSI is updated as needed when any changes or additions are made, and it is retained for the life of the process or equipment plus 30 years.

Established procedures, documented in Refinery Instruction RI-362 "Process Safety Information" (Chevron, 2013g), require that PSI be up-to-date and accurate, and be readily available to employees participating in PHA. The Facility keeps PSI current by following established MOC and PSSR programs, discussed further below. Personnel have access to either the hard copies or electronic copies of PSI on a 24-hour basis, which enables personnel affected by the process the ability to identify and understand the hazards posed by each process. The following PSI is particularly important to the Facility's prevention program:

- Information pertaining to the materials in the process:

- Material safety data sheets (MSDS) are maintained for each regulated substance, and include the following information: toxicity information, permissible exposure limits, physical data, reactivity data, corrosivity data, and thermal and chemical stability data.
- Maximum Intended Inventory calculations/worksheets.
- Information pertaining to the technology of the process:
 - Process flow diagram (PFD) for each process (and process flow and control diagrams).
 - Process chemistry (included in Operating Manuals).
 - Safe upper and lower operating limits and an evaluation of the consequences of deviations from those limits (included in Operating Manuals and Safety Instruction Sheets).
- Information pertaining to the equipment in the process:
 - Materials of construction.
 - Electrical area classification.
 - Relief system design and design basis.
 - Piping and instrumentation diagrams (P&IDs).
 - Ventilation system design.
 - Design codes employed.
 - Material and energy balances.
 - Safety systems.
 - Electrical supply and distribution systems.
 - Equipment specification documentation.

The Facility's PSM program requires that personnel from the Facility verify that the equipment complies with recognized and generally accepted good engineering practices (RAGAGEP). Personnel are also required to verify that all equipment is designed, maintained, inspected, tested, and operated in a safe manner. Under Chevron's PSM program, all new designs must also follow the CES, unless an exception is made through a documented waiver process that includes reviews and approvals. Other methods to ensure compliance with CES include Lead Engineer approval of all engineering work orders and a Quality Management process to reinforce craft quality.

1.2.1.2 Process Hazard Analysis

In accordance with RI-363, “Process Hazard Analysis” (Chevron [n.d.6]), Chevron conducts a PHA on each process unit at the Facility to systematically assess and reduce risks associated with loss of containment of hazardous substances. The RI-363 is also designed to satisfy the requirements of Section 2760.2 of the Cal/ARP regulations (Chevron, 2013h). Initial PHAs have been completed on all existing process units and are performed for new processes or major modifications to existing processes. Chevron revalidates PHAs every five years to ensure the analysis is current and accurate.

PHAs are performed with the following objectives:

- To identify the hazards of the substances and of the process;
- To identify external events (including seismic events) that could lead to a release;
- To identify possible equipment failures or human errors that could lead to a release;
- To evaluate the potential consequences of an accidental release;
- To evaluate the safeguards used to prevent or mitigate an accidental release;
- To evaluate the likelihood of an accidental release; and
- To propose recommendations that would reduce the risks.

Additionally, human factors and facility siting issues are addressed in conjunction with each PHA and inherently safer systems reviews are conducted to identify and implement the most feasible inherently safer risk reduction strategies.

Each PHA is conducted by a multi-disciplinary team. The PHA team is generally composed of a trained PHA facilitator, a process engineer, a design engineer, an operations representative, and other specialists when needed (i.e., plant protection personnel, mechanics, inspectors, equipment reliability specialists, environmental specialists, safety engineers, etc.). The team considers the possible causes and potential consequences of deviations to identify hazardous conditions, analyze existing safeguards, and make recommendations for changes where appropriate. The PHA team uses a qualitative evaluation tool, the Chevron Integrated Risk Prioritization Matrix, to assess the severity, likelihood, and relative risk of each cause-consequence scenario. The PHA documentation is retained for the life of the process plus 30 years.

The Facility uses the hazards and operability (HAZOP) study and "What-if/Checklist" methodologies to conduct PHAs, selecting the appropriate methodology based on the complexity of the process.⁴ Most continuous processing/circulating systems are analyzed using the HAZOP methodology. Certain support systems such as chemical injection facilities, utility systems, truck and railcar loading, or flare systems are usually analyzed using the "What-if" methodology. The "Checklist" methodology is used to address Human Factors and Facility siting issues.

PHA recommendations not requiring a process unit shutdown are required by the RISO to be completed within one year. RI-363 provides that recommendations requiring a process unit shutdown must be completed during the first regularly scheduled turnaround of the process. Some recommendations may require consideration of temporary measures to mitigate the risk until the final solution can be completed. The business unit manager for the process unit that is the subject of the corrective action recommendation works in consultation with the technical, maintenance, and reliability departments to determine whether the proposed corrective action can be safely implemented during the next scheduled turnaround. In making this determination, the business unit manager considers, among other things, the scheduled scope of work and whether the corrective action can be accomplished within that scope, the impacts on other units, and whether the impacts associated with delay is greater than the potential impact associated with implementing the corrective action during the scheduled turnaround.

Engineered leak repairs are widely used in the refining industry for various purposes, and not all are related to hydrocarbon or chemical leaks. Generally, leak repairs can be divided into three categories: repairs to utility systems such as steam and water, minor emission reduction measures, and repairs to hydrocarbon/chemical systems. Engineered leak repairs for piping in hydrocarbon/chemical systems are covered by *American Petroleum Institute (API) 570 - Piping Inspection Code: In-service Inspection, Rating, Repair, and Alteration of Piping Systems* (API 570, 2009), whereas leak repairs for utilities and minor emission reductions are not. Leak repair solutions for utilities systems and

⁴ HAZOP and What-If/Checklist are two methods for conducting a Process Hazard Analysis (PHA). A HAZOP study systematically evaluates a planned or existing process for potential failures or problems. A HAZOP is performed by a team of experts from multiple disciplines in a creative brainstorming, systematic approach to identify potential failures or problems that could lead to undesirable consequences. The What-If/Checklist method combines a creative, brainstorming team approach with set of standard written lists that identify hazards, design deficiencies, and potential problems associated with common equipment or operations (CCPS, 2008a).

regulatory-driven emissions reductions often become permanent, for instance injection of packing material into a valve packing gland to meet strict volatile organic compound (VOC) standards applicable in the Bay Area. Additionally, not all leak repairs in hydrocarbon service are driven by a physical leak; many are implemented as preventative purposes based on inspection data.

The Facility has various “Refinery Instructions” (RI), which are work practices and operating procedures, and standards that address the appropriate time frame for removal of a leak repair, including RI-621, “On-line Leak Repair/Leak Seal” (Chevron, 2012c) and RI-370, “Management of Change” (Chevron, 2013b). Generally, RI-621 provides that the “expiration date” of an engineered leak repair should be established and tracked in the leak repair database, and should be based on available maintenance opportunities and established criticality. Replacement of an engineered leak repair with permanent repair materials is made at the appropriate maintenance opportunity, and for purposes of tracking and closure, the expiration date generally corresponds to the next planned turnaround based on a technical review. On the initial expiration date, the change is reviewed to determine whether to extend or remove the change, and a decision to extend a temporary change must be approved consistent with the process set forth in RI-621 and RI-370. Both Cal/OSHA and the County (acting pursuant to the Richmond Industrial Safety Ordinance (RISO)) have authority to review the Facility's leak repair database at any time.

Those engineered leak seals cited by Cal/OSHA following the August 6, 2012 incident that relate to mechanical integrity have been replaced with permanent repairs. The engineered leak seals in hydrocarbon service in the crude unit, none of which were the subject of Cal/OSHA citations following the August 6, 2012 incident, were also replaced before the crude unit restarted in April 2013.

Resolutions of PHA recommendations are tracked and managed in the PHA Database. The database is the permanent record for each recommendation. The database includes the original team findings, the plan to resolve the potential hazard, when the action is to be completed, and the work performed to resolve the recommendation. The database also records the person and department responsible for completing the recommendation.

1.2.1.3 Operating Procedures

Clearly written safe work practices and operating procedures, especially for high-risk critical tasks, are important for the safe operation of the Facility and reduce the likelihood of a release of hazardous chemicals or energy that could impact employees, the community, or the environment. The Facility's RI-102, “Procedures for Instructions and Standards” (Chevron, 2009b), the Electronic

Operating Manual (EOM) Guidebook (Chevron, 2011d), and RI-374, “Safe Work Practices” (Chevron, 2012d), articulate the Facility's requirements designed to ensure that operating procedures and safe work practices are consistent and accurate.

Safe work practices include, but are not limited to:

- Respiratory Protective Equipment and Ventilation (RI-338; Chevron, 2014a);
- Hot Work and General Work Permits (RI-341; Chevron, 2013a);
- Control of Entry Into Process Areas (RI-375; Chevron, 2013k);
- Electrical Safe Work Practices (RI-389; Chevron, 2013m);
- Safe Firing of Furnaces and Boilers (RI-9025; Chevron, 2012e);
- Control of Hazardous Energy (RI-9900; Chevron, 2013n) (includes lockout and tagout and lines and equipment opening); and
- General Procedures for Entering and Working in Confined Spaces (RI-9920; Chevron, 2013p).

The operating manuals include the following sections and appendices:

- Process description;
- Normal operations, including startup and shutdown;
- Emergency procedures, including shutdown;
- Routine duties;
- A Consequences of Deviation (COD) table which identifies safe operating limits and the consequences of operating outside those limits. The COD tables explain the steps to correct or avoid the consequences of deviating outside the identified operating limits, including initiation of emergency shutdown;
- A safety section which provides a brief description of the chemicals and the associated hazards (including special or unique hazards) and engineering and administrative safeguards (i.e., ventilation, personal protective equipment (PPE) used to prevent exposures, etc.); and
- A description of all safety systems (i.e., alarms, interlocks, shutdowns), their functions, and their set points.

The Facility's Electronic Manual Management System (EMMS) provides that operations and maintenance (O&M) procedures and manuals are kept both

current and accurate. The EMMS database provides employees a method to review and update documents according to a regular schedule. Operations procedures and manuals are reviewed at least every three years. Maintenance procedures are reviewed every five years.

The MOC process, described further below, is required for all non-cosmetic changes to procedures and manuals. Any revised documents are routed through the area business unit (ABU) for review and approval.

In addition, at the end of each calendar year, each ABU Manager is required to certify that the operating procedures for their area are current and accurate as part of the Facility's annual compliance certification process.

These procedures are also intended to satisfy the requirements of Section 2760.3 of the Cal/ARP regulation, Operating Procedures. This section covers the steps for each operating phase, operating limits, safety and health considerations, and safety systems and functions.

Following the August 6, 2012 fire, the Facility has developed and deployed a new Leak Response Protocol (Chevron Data Transmittal #87, 2014) for evaluating leaks and shutting down equipment. This new protocol has been shared with Contra Costa Health Services (CCHS), Cal/OSHA, and the CSB, as well as other refineries and industrial facilities in Contra Costa County. To ensure competency in the new protocol, new training has been developed for impacted employees, and implementation of this training is being monitored by Cal/OSHA consistent with the terms of the August 5, 2013 terms of probation. The Facility has also modified its pre-incident scenarios to provide guidance concerning equipment positioning, and is in the process of reviewing its design and fire-prevention standards for large fractioning towers, with proposed enhancements scheduled to be approved in 2014.

1.2.1.4 Training

The Facility training program is intended to provide employees with the necessary skills and knowledge in order to perform their jobs in an incident-free manner, and to satisfy the requirements of applicable laws and regulations.

One of the purposes of the written training plan for the Facility is to provide affected personnel with an understanding of the types and causes of potential incidents or deviations within the process, and the hazards associated with the process.

The operator training plan is outlined in an Operations Training Process Manual (Chevron, 2009a). Maintenance personnel training is described in RI-368, “Mechanical Integrity” (Chevron, 2013j), and contractor training is addressed in RI-366, “Contractors” (Chevron, 2013i). The training program is also intended to satisfy the requirements of Section 2670.4 of the Cal/ARP regulation and is comprised of the following:

- Fundamentals training;
- Plant or equipment specific formal training;
- Training provided as a result of a MOC, which includes training on updated or new procedures;
- Refresher training; and
- Training documentation.

The training program requires that all Facility operators (i.e., qualified people that control the functioning of a machine or process) receive training in safe work practices and basic operating principles prior to assignment. The operators must receive training specific to the operations of each process once they are assigned to a process unit. The training criteria are documented in job description documents that list the knowledge required (i.e., safe operating limits, safety system setpoints) and skills to demonstrate (i.e., emergency shutdown, lockout/tagout procedures). Various means are used to verify competency, including written and oral examinations, demonstrations, and on-the-job training. Documentation of the training is forwarded to the Chevron Development Department for filing and tracking.

Refresher training on specific operating procedures (i.e., normal operations, startup, shutdown); critical, seldom-done tasks; emergency procedures; MOC reviews; safe work practices (i.e., in plant hot work, lockout/tagout); and company-wide practices is provided. Examples of the types of training and refresher training an operator will need to remain qualified for their position include:

- Computer based training on job specific PSM requirements.
- Simulator or oral discussion/demonstration when applicable.
- Computer based training on safe work practices.
- Just in time training on startup, shutdown, and related procedures before turnarounds.

In addition, general training includes monthly “hypotheticals” or table top drills and quarterly discussion of process safety topics (Chevron, 2009a).

The training schedule was developed with employee consultation and requires refresher training to be conducted, typically every three years. Training documentation is tracked in the training database or crew turnover logs.

Training may also be required as a result of the MOC process. The Facility requires in RI-370, “Management of Change” (Chevron, 2013b) that the necessary training is conducted prior to implementation of the change to satisfy the MOC requirements of Section 2760.6 of the Cal/ARP regulation.

Since the August 6, 2012 fire, Chevron has been working to enhance the requirements for training and competency for leadership, inspections, and technical assessments. The essential inspector competencies have been identified and individual evaluations and training plans are being developed to ensure inspectors meet the identified competency requirements. Additionally, training for determining minimum thickness and fitness for service of individual piping components has been enhanced. This training program is being implemented consistent with the terms of probation agreed to on August 5, 2013, as monitored by Cal/OSHA.

1.2.1.5 Mechanical Integrity Program

Proper design and maintenance of equipment and safety systems is essential to prevent releases of hazardous materials. The Facility has developed a mechanical integrity program to also satisfy the requirements of Section 2760.5 of the Cal/ARP regulation. Mechanical integrity requirements of the PSM standard include establishing written procedures to maintain ongoing integrity of process equipment, training for workers involved in maintaining integrity of process equipment, and inspections and testing of the mechanical integrity of process equipment.

The Facility's mechanical integrity program applies to fixed and rotating equipment, instrumentation, and electrical systems. This includes pressure vessels, storage tanks, piping systems (including piping components such as valves), compressors, pumps, pressure relief devices, and vent systems, all of which the Facility requires to be inspected following API guidelines. The mechanical integrity program also applies to emergency shutdown systems and process controls, including monitoring devices, sensors, alarms, and interlocks.

RI-368, “Mechanical Integrity” (Chevron, 2013j), describes the Facility’s policy and standards for the mechanical integrity program, which consists of the policies and procedures described below.

- **Quality assurance procedures** – Members of the engineering, maintenance, inspection and purchasing departments each have specified roles in assuring mechanical integrity, and receive necessary training to fulfill those roles. These personnel are required to review all new equipment against the purchasing documents (which include, for example, equipment specifications and fabrication requirements) to ensure that the equipment is fabricated in accordance with the specifications which are typically those provided by the American Society of Mechanical Engineers (ASME), American Welding Society (AWS), and the National Board Inspection Code (NBIC). They also conduct checks and inspections to ensure that the equipment is installed properly and is consistent with the design specifications and the manufacturer’s instructions. The preceding elements of the quality assurance program are often performed in conjunction with the MOC and PSSR programs. The Purchasing and Materials Management Department, in conjunction with engineering, reliability and maintenance personnel, develops and maintains purchasing documents for spare parts. This is intended to ensure that all maintenance materials and spare parts are suitable for the process application.
- **Written maintenance procedures for process equipment** – Written procedures (including step-by-step instructions and required personal protective equipment) are developed for maintaining process equipment. The regularly scheduled maintenance (preventive maintenance) requests are automatically generated by a computer-based maintenance work management system. Non-preventive maintenance activities are also performed through the work management system (i.e., operators and engineers submit work requests to be scheduled by the Maintenance Planner/Scheduler). The maintenance employee completes the work order documentation and the maintenance history records are updated in the work management system. The Facility’s EMMS is designed to keep maintenance procedures and manuals both current and accurate. The EMMS database provides employees a method to review and update documents according to a regular schedule. Maintenance procedures are reviewed every five years.
- **Maintenance employee training** – The Facility carefully assesses each applicant for employment as maintenance personnel for skills and knowledge pertinent to their required job tasks. Additional skills training is provided on an as-needed basis or when required by applicable codes and standards. The

Facility's Development Department maintains documentation of skills training (i.e., union training program, community college training, specialty equipment training) and compliance training for maintenance employees. During initial employee training and refresher training, maintenance employees are provided with an overview of the process, the hazards associated with the process, and safe work practices. The Development Department maintains initial and refresher training records including content of training, instructor, and means used to verify competency. All welding related work and records are required to be monitored and controlled through the Facility Inspection Department in accordance with ASME, AWS, and NBIC requirements.

- **Inspection and testing procedures for critical equipment** – Inspection and testing procedures and frequency of testing for each piece of critical equipment are developed and documented by the Equipment Reliability group. The procedures and frequency are based upon jurisdictional requirements, manufacturer's recommendations, good engineering practice, operating history, and failure prediction and prevention analysis. Completed inspection and test documents (which include the inspector's name; date of the inspection or test; identification of the equipment, inspection and test procedures; and the results of the inspection or test) are retained by the maintenance and reliability department. Equipment Inspectors or Reliability Analysts review the results of each inspection or test to ascertain whether the equipment is within the acceptable limits and to determine if the frequency of the inspections should be adjusted. Procedures require that equipment outside of the acceptable limits is removed, repaired, or replaced, unless temporary protective measures can be put in place until the deficiencies are corrected. Inspection and test results are required to be maintained for the life of the equipment. Some examples of inspections and tests include internal and external inspections, thickness monitoring, ultrasonic/radiography inspection, hydrotesting, and infra-red scans. Instrumentation and control systems are also tested to ensure they will function as intended.

Following the August 6, 2012 fire, the Facility has taken steps to enhance its mechanical integrity program to ensure the Facility properly identifies and monitors piping circuits for appropriate damage mechanisms. As a first step, the Facility added a Fixed Equipment Integrity Manager to oversee development of the program enhancements and implement the enhancement on a go-forward basis, among other things.

The Facility has also developed a new process to review all damage mechanisms that may affect a given plant at the process level. This new process, which also responds to a CSB urgent recommendation, requires a team of subject matter experts to review, analyze, and make recommendations concerning damage mechanisms and how to mitigate their effect on each process unit. This review of damage mechanisms is assisted by the Facility's Fixed Equipment Integrity Group and the results are then provided to the PHA team for their consideration and review as that team formulates its recommendations. This new process, called the Damage Mechanism Review process, was piloted at the Facility in 2013 and has now been made a required element in the Process Safety Management process at the Facility.

In addition, the Fixed Equipment Integrity Group will be developing asset integrity plans that address damage mechanisms and recommendations for mitigation of risks for each process unit at the piping circuit level. Eventually, Chevron plans to integrate these circuit specific asset plans with the separate damage mechanism review process. A pilot of the asset integrity planning process has been performed for the crude unit.

Chevron has also developed and implemented processes for additional oversight of mechanical integrity-related recommendations from the Facility's Fixed Equipment Integrity Group, Chevron's ETC, and other subject matter experts, as well as from general industry alerts. A review of mechanical-integrity standards has been undertaken and these standards will be compared to existing Chevron standards to identify any discrepancies and establish a plan to reconcile those discrepancies on a go-forward basis.

In addition, the Fixed Equipment Integrity Group at the Facility has developed an Integrity Threat Process, which has been deployed at the Facility and which establishes a regular process for review of potential mechanical integrity threats and development of action plans to address such threats. Finally, the Facility has modified its Reliability Opportunity Identification/Intensive Process Review process and its PHA procedure, to incorporate consideration of damage mechanisms. Considering damage mechanisms when conducting PHAs was an element of the CSB's recommendations to Chevron and is included in Chevron's probation terms.

1.2.1.6 Management of Change

Changes within a refinery are sometimes necessary to address safety, environmental, and operational concerns. A change made in one part of the process or other processes may have unintended effects on other parts of the process because the Facility is an integrated system. These changes must

therefore be scrutinized in advance to avoid adverse effects to worker and public safety and to the environment. The Facility has a written MOC procedure, documented in RI-370, “Management of Change” (Chevron, 2013b). This procedure is intended to also satisfy the requirements of Section 2760.6 of the Cal/ARP regulation. The MOC procedure addresses management of the following types of changes:

- Process chemicals (i.e., raw materials, intermediate products, solvents);
- Technology (i.e., operating parameters, catalysts, rates);
- Equipment (i.e., materials of construction, equipment specifications); and
- Procedures (i.e., emergency response, maintenance, operating)

RI-370 establishes a hierarchy for MOC documents. The Facility’s MOC process, as described in RI-370, does not apply to “replacement in kind,” which is defined as a replacement that satisfies the design specifications. The design specifications are established by various standards organizations, including ASME, NFPA, American National Standards Institute (ANSI), as incorporated by California’s building and fire codes.

The Facility classifies changes as permanent, temporary, or emergency. Emergency changes are allowed during off-hours and holidays; however, at a minimum, the MOC process requires that the impact of the change on health and safety has been assessed, communication and training requirements have been met, and when required, a PSSR is to be completed prior to start-up. Temporary changes require the identification of a maximum allowable time frame for the change. All temporary MOCs will be given an initial maximum expiration date of one year. They can be extended an additional one year at a time following the health, safety, and environmental (HSE) process with management approval. Changes to Facility equipment or processes are implemented as a result of the Facility’s business and safety decision-making process. An MOC (i.e., the overall process for managing changes as well as the individual analysis of changes undertaken using the process, such as a change in metallurgy or a change in operating temperature) is typically initiated by the individual who has been assigned the task to carry out a proposal as part of the routine work process.

The MOC procedure requires Facility personnel to assess the potential impact of the change on safety and health through a Health and Safety Evaluation procedure for most changes. A HAZOP study or “What-if/Checklist” is conducted for additions and major changes that require a more structured evaluation. The following steps are required by the MOC procedure:

- Equipment must be fabricated and installed in accordance with the design specifications;
- Employees whose job tasks are affected by the change must be trained prior to the startup of the process;
- PSI must be updated as necessary; and
- Operating procedures must be updated as necessary in accordance with the change being made, and reviewed by a subject matter expert (Chevron, 2011d).

Simple changes require only communication of the change taking place. Persons affected by a change will be sent a notification of the change prior to being affected by that change. For more complex changes, a training package is developed, typically by the area trainer, and delivered to the affected employees, either on shift for minor changes, or in a classroom setting for major changes.

The person that authorizes the start-up of a change is responsible for the determination that the assigned individuals have completed all required tasks and reviews identified on the MOC form.

If it is considered necessary to use marked-up copies of P&IDs temporarily to expedite start-up, the MOC tracking system is used to verify completion of the update process. The individual that authorizes the start-up of any change is responsible for ensuring that all PSI, including P&IDs, are updated prior to start-up of the change. The P&ID update process is described in RI-362, "Process Safety Information" (Chevron, 2013g).

The MOC records are tracked according to assigned tracking numbers. The MOC records and documentation of completion of the tasks and reviews are maintained for the life of the process plus 30 years.

1.2.1.7 Pre-Startup Safety Review

The Facility has a written PSSR procedure and checklist, which is documented in RI-367, "Pre-Startup Safety Review" (Chevron, 2011c). This procedure is intended to also satisfy the requirements of Section 2760.7 of the Cal/ARP regulation. The Facility's PSSR procedure is designed to provide for a system of checks and verifications to ensure that equipment is suitable for service and meets required specifications prior to startup in order to prevent the accidental release of hazardous materials. In addition, PSSRs require that necessary operating, maintenance, and emergency procedures have been written and that employees have been trained to safely operate the equipment.

The PSSR process takes place prior to start-up of a new unit or the startup of an existing unit after a shutdown/turnaround. Changes requiring an MOC may also trigger a PSSR. The Facility PSSR program does not require PSSRs for MOCs initiated only for a change to PSI as such changes do not require the startup/shutdown of a process unit or equipment.

The PSSR Facilitator convenes a team with knowledge of the process and expertise in their field. Team members can include representatives from the business unit, maintenance group, engineering groups, and others depending on the nature of the change. Team members are responsible for verifying that the following actions have been taken prior to the introduction of regulated substances:

- Construction and equipment are determined to be in accordance with design specifications;
- Safety, operating, maintenance, and emergency procedures are in place and are adequate;
- For new facilities, a PHA has been performed and recommendations have been resolved or implemented before startup;
- PSI, including P&IDs, has been generated or updated, as appropriate;
- Communication to and/or training of each employee involved in operating the process has been completed, and
- Quality assurance goals of mechanical integrity have been met.

Verification of these steps is to be performed by the appropriate personnel from the team, and requires sign-off in the MOC and/or PSSR database.

All required signatures must be obtained and any exceptions documented prior to startup. PSSR exceptions are outstanding items that may or may not be required for safe startup. The PSSR facilitator and the appropriate Refinery Business Manager or delegate must review and agree on exceptions prior to start-up of the unit or equipment. Exceptions will be tracked to completion in the MOC or PSSR database. Each exception must be specific, assigned to an individual, have a due date, and be identified if it must be completed prior to start up. Authorization for startup requires completion of Appendix I, II, or III of RI-367 (Chevron, 2011c).

As part of the repair of the crude unit in response to the August 6, 2012 fire, the Facility replaced all fire-damaged piping in the crude unit subject to high-temperature sulfidation conditions with 9 Chrome alloy pipe. The piping

upgrades and other repairs to the crude unit were completed and the crude unit restarted in April 2013, following a rigorous and extensive PSSR process to ensure a careful and safe restart of the Unit. This PSSR process was reviewed in advance by Cal/OSHA and the EPA, and Cal/OSHA conducted a 4-day on-site audit of the PSSR process in early-April. Following completion of its audit, on April 5, 2013 Cal/OSHA lifted the Orders Prohibiting Use that had been in place since immediately following the August 6, 2012 fire.

1.2.1.8 Compliance Audits

The Facility's Compliance Audit Program, documented in RI-373, "Compliance Audit Policy" (Chevron, 2009c), is intended to also satisfy the requirements of Section 2760.8 of the Cal/ARP regulation. Audits help verify compliance with established standards/regulations and ensure that process safety systems are implemented as designed. Under the Facility's Compliance Audit Program, trained personnel must perform internal PSM compliance audits at least every three years to review and evaluate the written documentation/records, and implement the PSM Program and Cal/ARP prevention program. Compliance audits can cover the entire Safety Program, or can focus on individual elements of it, subject to the discretion of the auditor.

The Chevron Corporate Operational Excellence Audit Group assigns an Audit Team Lead. This person is responsible for leading the audit team and ensuring all of the goals and objectives of the audit are fulfilled. The balance of the audit team is to be comprised of qualified personnel knowledgeable in the process. The PSM Audit Team Lead fulfills the role of Audit Liaison and is responsible for making notifications, interview schedules, and determining meeting locations. The Operations Excellence/Process Safety Management (OE/PSM) Manager is to assist in the removal of barriers which may impede the team's ability to succeed and must work with the other resource owners (i.e., managers of the different work groups assigned to assisting in closing audit findings) to ensure that findings requiring mitigation have adequate resources committed to implement the mitigation measures in a timely fashion.

The Compliance Audit Program provides that the audit team shall utilize a field assessment and audit checklist to perform:

- An assessment of the adequacy of documented safety program requirements, including operating procedures such as RIs;
- A review of records (i.e., completed hot work permits, MOC documents, incident investigations, equipment records) to assess implementation of the documented procedures;

- Interviews with employees to assess their understanding of applicable programs (for example, whether personnel have a basic understanding of the mechanical integrity program); and
- Interviews with key personnel (those with primary responsibility for each element within the Safety Program).

The Compliance Audit Program requires that team members formulate findings for improvement. The results of the compliance audit are to be communicated to members of management during a closing meeting and in an audit report. The appropriate PSM element owners are responsible for reviewing the findings, determining appropriate resolutions, assigning responsibility for each resolution, and compiling status reports of progress made in implementing the resolutions. The periodic status updates are maintained in an audit database. The Facility retains the two most recent compliance audit reports. The audit program requires that the Facility track to final disposition the resolutions formulated during all compliance audits.

1.2.1.9 Incident Investigations

The Facility's incident investigation procedure, documented in RI-371, "Near Loss, Event Reporting, and Incident Investigation" (Chevron, 2014b), is intended to satisfy the requirements of the PSM standard as well as of Section 2760.9 of the Cal/ARP regulation. RI-371 establishes procedures for investigating each incident that results in, or could reasonably have resulted in, an accidental release of a regulated substance causing injuries or property damage. Incident investigations provide Chevron with the means to identify root causes or systemic factors and implement solutions to prevent future incidents.

RI-371 requires that personnel must promptly report any abnormal event or near miss, including those with the potential for catastrophic release. All events are to be reported into the Facility's incident database. Personnel trained in the methodology to be used are assigned as investigation team leader and/or investigation team facilitator. The experience and number of the other team members are dependent upon the nature of the incident. Typically, the incident investigation teams are comprised of a management sponsor, team leader, and other employees (including contract employees) knowledgeable in the operation, design, and maintenance of the process.

Incidents are classified as Level 1, 2, or 3 based on a variety of impacts or potential impacts, including but not limited to personal injuries, severity of environmental impacts, and degree of damage resulting from a fire or explosion. Level 1 is the least severe, with Level 3 being the most severe. Significant

incidents (Level 3 severity classification) require the use of the TapRoot® methodology for root cause analysis, which incorporates human factors in the investigation process. TapRoot® is a systematic process, software, and training for finding the root causes of problems; it is used to investigate and fix the root causes of major accidents, everyday incidents, minor near misses, quality issues, human errors, maintenance problems, medical mistakes, productivity issues, manufacturing mistakes, and environmental releases.

The incident investigation team leader is responsible for initiating the investigation as soon as possible, and no later than within 48 hours of the time of the incident or near miss. The team lead selects team members for Level 1 and 2 investigations, and coordinates and supervises investigation team activities. Team members, with team leader/facilitator guidance, collect and analyze facts; identify root causes; develop appropriate solutions in order to avoid a repeat occurrence; and prepare the initial investigation report. The management sponsor has overall accountability for the investigation and its documentation, confirms team leader and members, assigns team members for Level 3 investigations, ensures needed resources are available, and reviews and approves the final investigation report.

The incident investigation program requires that report findings and recommendations are promptly addressed and resolved in a timely manner. The functional work group manager is responsible to ensure the corrective actions are completed in accordance with RI-371 (Chevron, 2014b).

The investigation report must be entered into the Facility's computerized incident database, along with lessons learned and recommendations to prevent future occurrences. Recommendations must be tracked until completion. The Facility regularly reviews metrics to prevent corrective actions from becoming overdue and also tracks the status of investigations so they are completed in a timely fashion, in accordance with RI-371. An Operational Excellence Reliability Intelligence (OERI) database shows when corrective actions are overdue. For every Major Chemical Accidental Release investigation, corrective actions must be completed within a year of the investigation close-out meeting unless requiring a shutdown. Every corrective action has a verification and validation process. Copies of the investigation reports are retained for a minimum of five years.

Investigation results are reviewed with employees (including contract employees) whose job tasks are relevant to the findings in regular safety meetings, in other acceptable forums, or through incident bulletins. The management team discusses incidents that resulted in significant consequences as part of the daily

safety discussions. Alerts and Bulletins distributed from other Chevron facilities are reviewed during monthly safety meetings.

Initial reporting of any incident to CCHS is done in accordance with the CCHS “Hazardous Materials Incident Notification Policy.” This includes 72-hour and 30-day follow-up reporting and establishes minimum requirements for final reporting. The final incident report includes at a minimum: date of incident, date investigation began, a description of the incident, the factors that contributed to the incident, and recommendations resulting from the investigation. The incident investigation report shall be made available to CCHS or other applicable agencies as appropriate. These requirements are detailed in RI-371 (Chevron, 2014b).

1.2.1.10 Employee Participation

The Facility relies on the expertise of employees and contractors at all levels and disciplines to optimize operations and safety. This is achieved by consulting with employees to ensure consideration of their knowledge and experience in all applicable areas of the prevention program. The Facility has developed a written plan of action regarding employee participation in all aspects of the prevention program. The written program, which is intended to also satisfy the requirements of Section 2760.1 of the Cal/ARP regulation, is documented in RI-361, “Employee Participation Plan” (Chevron, 2013f). The Facility's employee participation program fosters ongoing engagement between management and employees and encourages active participation in the design, development, implementation and continual improvement of process safety activities, and systems.

The written employee participation plan (RI-361) and other Facility policies—including Process Hazards Analysis (RI-363; Chevron, 2013h); Operator Work Instructions (RI-124; Chevron, 2013e); Incident Investigations (RI-371); Management of Change (RI-370; Chevron, 2013b); Pre-Startup Safety Review (RI-367; Chevron, 2011c); and the Operations Training Process Manual—provide that:

- Employees and their representatives are consulted on the conduct and development of PHAs conducted to comply with Section 2760.2 of the Cal/ARP regulation. The Facility requires participation by plant operations and engineering personnel as members of the analysis team. Other employees with responsibilities relating to specific processes are consulted prior to and during the PHA. Employee involvement is documented in PHA reports.

- Employees and their representatives are consulted on the development of all elements of the prevention program and the emergency response program. Examples of participation include:
 - O&M employees are involved in the development and review of procedures, and their participation is documented in the EMMS;
 - O&M employees are members of the required incident investigation teams, and their participation is documented in the incident report;
 - O&M employees are consulted regarding the appropriate type and frequency of training;
 - O&M employees participate in various safety activities: Incident and Injury Free Committee, Joint Health and Safety Meetings, PSM Steering Committee, and their participation is documented in meeting minutes; and
 - O&M employees participate in MOC activities such as Health and Safety Evaluations and PSSRs, which are documented in the MOC database.

1.2.1.11 Hot Work Permit

Controlling ignition sources is vital to the Facility's PSM program and risk management plan. The Facility has a hot work permit program to prevent inadvertent ignition of flammables or combustibles when performing jobs such as welding, and to ensure that any fires which may occur can be readily suppressed and extinguished. The Facility's hot work permit program is documented in RI-341, "Hot Work and General Work Permits" (Chevron, 2013a) and is also intended to satisfy the requirements of Section 2760.11 of the Cal/ARP regulation. The hot work permit program requires that employees complete permit requirements certifying that the applicable portions of the fire prevention and protection requirements are implemented prior to beginning hot work operations. Management personnel must authorize any hot work (e.g., cutting, grinding, burning, welding, brazing) to be performed in a unit and ensure appropriate safety precautions are taken prior to initiation of the work.

The fire prevention procedure, covered in RI-341, restricts hot work in certain areas. When grinding, burning, welding, or brazing work is needed in these areas, an ignition source permit must be initiated by the Maintenance supervisor and approved by the local Operations supervisor and under certain circumstances additional approvals are required. The permit is terminated when continued use of the ignition source is hazardous, when conditions of its issuance change, or when the permitted hot work has been inactive for more than two hours (unless tests show that conditions are still non-hazardous).

The Facility maintains three copies of the ignition source permit. The first is required to be posted at the physical location of the hot work for the duration of the work. The second is to be provided to the control room file. The third must be provided to the Facility's internal emergency services department (ESD), where it is kept on file for at least 12 months after the date of issue. The permit shall contain the following information:

- The effective date and time;
- The place of use;
- The hours during which the source of ignition may be used;
- The specific location or piece of equipment where the source of ignition will be used;
- The nature of the source of ignition; and
- Any special precautions or limitations to be observed before, during, or after the use of the source of ignition, including the need for a fire watch and fire hoses or extinguishers. The criteria for needing a fire watch are identified in RI-341. The responsibilities and authority of the fire watch are to continuously monitor assigned job(s), extinguish incipient stage fires, sound fire alarm when necessary, and to use Stop Work Authority if they think that work being performed is unsafe.

Trained personnel from the Facility's Emergency Services, Operations, and Maintenance departments are required to perform an inspection of the area to ensure the following prior to authorization of hot work:

- The source of ignition may be safely used. RI-341 requires that only approved apparatus be used and that personnel performing the hot work (including contractors) be informed of the hazards and are properly trained. Also, the flammable gas or vapor content in the air must be less than 10% of the lowest content that is flammable or explosive.
- Combustible materials in areas that will be exposed during hot work are protected or relocated.
- Proper fire extinguishing equipment is available to employees performing hot work.

Personnel in the control room must be notified prior to initiation of the hot work to make them aware of the ignition source. This awareness allows personnel in the control room to promptly contact the fire watch and personnel performing hot work if continued use of the source of ignition becomes hazardous.

No specific changes have been made to the hot work permit program as a result of the August 6, 2012 fire.

1.2.1.12 Contractors

The Facility's contractor program is documented in RI-366, "Contractors" (Chevron, 2013i), which is intended to satisfy the PSM requirements as well as Section 2760.12 of the Cal/ARP regulations. The contractor program requires that safety issues are addressed during contractor selection and that Chevron and the contract company share responsibility for the safety of all employees. The Facility and all contract companies are jointly responsible for safety and must ensure that contractor's employees are trained in and understand the following:

- Work practices necessary to perform the job;
- Hazards associated with a process;
- Applicable sections of the emergency response procedure. RI-400, "Emergency Response Plan" (Chevron, 2013c), which is incorporated into the training required by RI-366, "Contractors," provides the overall framework for the Facility emergency response plan (Chevron Data Transmittal #87, 2014). In addition to RI-400, the Facility has specific emergency plans for different areas, risks, or types of incidents. These include but are not limited to:
 - RI-406, "Fire Emergency Response" (Chevron, 2010a)
 - RI-410, "Marine Oil Spill" (Chevron, 2012a)
 - RI-414, "Off-site Material or Waste Spill Response" (Chevron, 2010b)
 - RI-417, "Liquid Petroleum Gas (LPG) Release Emergency Response" (Chevron, 2010c)
 - RI-422, "Hazardous Waste Treatment Center and Storage Facility Contingency Plan" (Chevron, 2013d)
 - RI-423, "Hazardous Waste Generator Contingency Plan" (Chevron, 2012b)
 - RI-440, "Emergency Plans for Total Power Outage" (Chevron, 2011a)
 - RI-480, "Emergency Action Plans" (Chevron, 2009d)
 - RI-481, "Employee Initial Emergency Response Test" (Chevron, 2011b); and
- Applicable safe work practices.

Chevron's Contractor Safety Management Program employs a system of controls which requires contractors to meet Chevron's standards and expectations for

supporting safe Facility operations to protect contractors, employees, the community, and the environment. The Facility requires that potential contract companies complete and return a pre-qualification questionnaire regarding their safety programs to the Facility's Contracts Administration group for review against established criteria. The questionnaire includes confirmation that the contracting company has an established written safety program, job qualification employee requirements, a program for random drug and alcohol testing, initial and refresher training programs, a behavior-based safety process, and a short service employee program. The contractor program also requires that metrics, such as Total Recordable Incident Rate, are also considered when selecting contract companies. The Facility's Contracts Administration group may also request that the contract owner submit additional documentation, such as safety training records/logs. The contractor office audit process also includes verification of appropriate skills and certification required to perform the job. Contract companies found to be acceptable against the established criteria are then logged into a "Preferred Contractors" list. The Facility's Contractor Health Environmental Safety Management (CHESM) database maintains files of the completed questionnaires and any additional information requested.

All contractor employees employed by the Facility are required to receive training required by RI-366 (Chevron, 2013i) before being allowed on-site at the Facility. Each contractor employee must complete a course in general Facility safety conducted by the Bay Area Training Corporation (BATC)/DISA Global Solutions or Occupational Safety Councils of America (OSCA), which offer DISA Safety Orientation Program (DSOP) and Nor-Cal/LA Refinery Safety Orientation (NCRSO/LARSO). In addition, the Safety Management Contractor Program requires that each contractor employee must complete a course in Incident and Injury Free Orientation (IIFO), emergency procedures and Facility-wide work practices specific to the Facility. Training is also given on process-specific hazards related to the area in which the contractor employee will be working. Contractors and all employees other than operators assigned to the specific process unit must sign in at the Facility's control room for the unit, review the ERP for the area before entering the unit, and sign out when leaving.

The Maintenance Department and Health, Environmental, and Safety Department periodically audit contractor companies. The frequency of the audits is adjusted according to safety performance history and the type of service being provided. The contract owner/CHESM administrator is responsible for ensuring that each contractor provides proper training and maintains documentation for each contract employee. The contract owner/CHESM administrator also monitors contractor performance (i.e., compliance with stationary source safe work practices, knowledge of types of work, and the hazards involved).

Documentation of the audits and on-site evaluations is maintained for a minimum of five years within the CHESM database.

It is also critical for contractors and Facility personnel to be aware of any unique hazards that may occur prior to performing their work. A Joint Job Safety Visit is performed by the local operators and the maintenance contractor prior to the commencement of work. Additionally, communication of hazards when changes take place is accomplished via RI-370, “Management of Change” (Chevron, 2013b); RI-9900, “Control of Hazardous Energy including Lock-out/Tag-out” (Chevron, 2013n); and/or RI-375, “Control of Entry into Process Areas” (Chevron, 2013k) processes.

No specific changes have been made to the contractor program as a result of the August 6, 2012 fire.

1.2.2 Accident History

The following accidents meet the definition of an accidental release according to CalARP Section 2750.9, were reported in previous Risk Management Plan (RMP) submissions, or were included in the 2008 EIR and retained here for continuity:

- **On June 19, 2012**, during maintenance of a pipe elbow, approximately one pint of a hydrocarbon oil mixture was released to the San Francisco Bay at the Long Wharf. A Community Warning System (CWS) Level 1 was issued and the material was contained with booms and pads.
- **On November 14, 2011**, hydrocarbons (vacuum residuum) were released during a filter change on the vacuum residuum pumps in the crude unit’s residuum filters (K1165). The released heavy hydrocarbons subsequently ignited. The crude unit was shut down and CWS Level 1 was activated. Thick black smoke was visible off-site; however, air sampling conducted by Chevron indicated that no hazardous or toxic substances were detected above Cal/OSHA Permissible Exposure Limits (PELs) or California Office of Environmental Health Hazard Assessment/Air Resources Board (OEHHA/ARB), Reference Exposure Level (RELs). One employee sustained minor burns to the face due to radiant heat exposure. The emergency shutdown resulted in flaring. According to Chevron, up to 35,000 pounds (lbs) of heavy hydrocarbons (vacuum residuum) may have been released. Additionally, 384 lbs of sulfur dioxide (SO₂) and 1.3 lbs of hydrogen sulfide (H₂S) were also calculated by Chevron to have been released.
- **On September 26, 2011**, tetramer product leaked from a cargo hose from Berth 2 of the Long Wharf. A total of approximately five gallons (or less) were released to the San Francisco Bay, which spread to an area of approximately

18 feet by 12 feet. According to the Emergency Release Follow-Up Notice Reporting Form filled out by Chevron, the leak was secured and both internal and external spill response personnel were notified and called in to the site. The release was contained with booms around the berthed vessel. The deployed boom was then replaced by a permanent fence boom, which provided full containment of the spill until a vacuum truck and weir type skimmer were able to recover the material. Workboats also swept the area with absorbent pads and booms. According to the report form, the oil sheen was no longer present on the surface of the water after cleanup and no sensitive areas were affected. Several agencies were on-site during these activities, including the U.S. Coast Guard, the CDFW, and the California State Lands Commission.

- **On March 23, 2011**, according to the Emergency Release Follow-Up Notice Reporting Form filled out by Chevron, during a routine pump procedure, a bleeder valve was left open which allowed a mixture of vacuum gas oil and aviation turbine gas jet fuel to release into a drip pan. The drip pan had small leaks, which resulted in the oil mixture to be released to the San Francisco Bay at the end of the Long Wharf causeway nearest to Berth 7. Approximately 200 square feet of surface water was affected due to the 24 gallons of oil that were released. The bleeder valve was closed upon discovery of the release, and the Chevron spill response team was called onto the site. A boom present under the Long Wharf for precautionary purposes contained the spill initially, and the response team further contained the spill with a second absorbent boom. Boat crews swept the area with absorbent material and vacuum trucks also collected oil, until oil was no longer visible. Chevron indicated that all Long Wharf drip pans were to be inspected and repaired if necessary, and that all drip pans would be replaced during the upcoming dry season.
- **On November 2, 2009**, a small amount of recovered oil containing light hydrocarbons (approximately one gallon) was released into the San Francisco Bay, resulting in a light surface sheen on the water which covered an area of approximately 45 square feet. The release was determined to be due to a pipe leak at the Long Wharf. The State Office of Emergency Services, the U.S. Coast Guard, CCHS, and the San Francisco RWQCB were notified of the release verbally. The leak was secured with two clamps, and the surface sheen was reported by Chevron to have immediately dissipated.
- **On June 21, 2009**, a sump overflow at the Long Wharf resulted in the release of approximately two gallons of a recovered oil and water mixture to the San Francisco Bay. An estimated 200 square feet were affected. The sump valves were immediately closed and the spilled oil mixture was secured with booms

and absorbents within approximately 25 minutes. The absorbent boom was removed from the area the following day. According to the Emergency Release Follow-Up Notice Reporting Form filled out by Chevron, the high level alarm on the sump was to be repaired and additional training to operations personnel was to be administered as corrective actions resulting from the incident.

- **On January 15, 2007, at 5:18 a.m.,** a fire occurred at the crude unit number four when a sulfidation corrosion thinned carbon steel section of the 4-inch-diameter wash-oil swing-out spool failed, releasing a mixture of wash-oil, vacuum gas oil and vacuum residual. A CWS Level 2 alert was issued by the Richmond at 5:22 a.m., followed by a CWS Level 3 siren at 5:30 a.m. In order to not accumulate larger quantities of unburned fuel, several small fires continued in a controlled manner until 2:14 p.m. One employee was treated for minor burns by the Chevron Fire Department and by an outside hospital. That employee was released and returned to work the same day. Another employee received on-site treatment and returned to work the same day. Monitoring conducted by the Facility in the neighboring community showed no evidence of adverse air quality levels. Subsequent corrective action included upgrading the metallurgy of the swing-out spool and replacing a gate valve. In addition, other similar gate valves in crude unit number four were replaced with more modern technology.
- **On August 17, 2006,** a nitrogen truck contractor was sent to the hospital for exposure to aqueous ammonia and H_2S from an unspecified unit. Approximately five to ten gallons of the substances were released due to an unreported cause. No additional information was provided on the CCHS Hazardous Materials Program Incident, Notification, and Complaint Report Form.
- **On October 21, 2003, at 12:40 a.m.,** while disconnecting a railcar, a momentary release of ammonia occurred at the Isomax ABU, spraying onto an employee. This resulted in burns to the employee's face and neck. The release did not result in any off-site consequences.
- **On September 4, 2003,** as the Poly Plant pump P-651A was being prepared for hot alignment and re-start, less than one barrel of Whole Polymer was released from an open 0.75-inch bleeder valve on the pump discharge pipe as the pump suction valve was being opened. The operator closed the suction valve to isolate the leak and the hot stock auto-ignited, resulting in a small fire with visible smoke. Plant operators isolated the leak and extinguished the fire within approximately three minutes. Concurrently, an approximate 4.0 (Richter scale) earthquake occurred in the vicinity of the plant resulting in a large "boom" sound. The Refinery Shift Coordinator,

unaware of the earthquake and assuming the sound was related to the fire in the plant, activated the CWS Level 3 alarm. An “all-clear” was issued less than an hour later when the CCHS and shift coordinator determined that the incidents were unrelated.

- **On August 9, 2003**, TP-603A, the main lube oil pump, shut down unexpectedly and would not restart due to a seized bushing on the shaft; the backup lube oil pump, TP-603B was out of service due to a routine check. This resulted in the shutdown of the K-600 Isomax recycle compressor due to low lube oil pressure at 1:52pm. Burners were shut off on furnaces F-610 and F-620 and operators began de-pressurizing the reactors per emergency procedures in order to decrease reactor bed temperatures. The feed was also pulled and the system depressurized. TP-603A was handed over to maintenance for repairs. At 6:10pm, K-600 restarted. Later, an increase in reactor bed temperatures was observed in R-610 and R-620. Operators then shut down K-600 due to inability to maintain seal oil flow. Operators de-pressurized the system to reduce reactor bed temperatures but bed temperatures remained high. Operators opened the emergency de-pressure valves and North Isomax was taken off of Flare Gas Recovery. Flaring was initially unstable with incomplete combustion, but stabilized after 10 minutes. CWS Level 1 was first activated just before 8:00 p.m. and at 9:19 p.m., CWS Level 3 was activated as a result of multiple agencies receiving odor complaints. All clear⁵ was issued at 11:09 p.m. Approximately 790 lbs of SO₂ was released from flaring due to the incident. Multiple hand-held analyzer samples were taken and results were found to be below detection level. One bag sample (of seven) showed a positive result for H₂S (0.1 ppm). According to a Chevron investigation of the incident, the root causes were determined to be: (1) a seized bushing on the shaft of TP-603A (equipment difficulty, unexpected failure) resulted in the inability to pump lube oil for K-600. Bushing failure/seizure is noted as an uncommon occurrence; (2) emergency procedures were unclear regarding when to discontinue effort to restart the compressor and fully de-pressure the unit (K-600) (human performance difficulty, management system); and, (3) flare was unstable with incomplete combustion due to design difficulty. In addition, Chevron identified the following corrective actions: (1) repair TP-603A bushing on shaft; (2) establish guidelines for what reactor temperature and pressures must be before attempting to restart the recycle compressor.

⁵ The term “all clear” is not a written finding resulting from the investigation; instead it is a term of art used by community warning system (CWS) operators and confirmed by Contra Costa County Health to indicate via phones, text messages, emails, social media (currently Facebook and Twitter), and the CWS public website that the hazard of concern no longer exists (Chevron Data Transmittal #87, 2014).

Review revised procedures with operating crew; (3) consider creating a simulator scenario for restarting the plant after an emergency loss of K-600 recycle compressor; and, (4) upgrade flare instrumentation to include relief gas flow indicators.

- **March 5, 2003:** The Head Operator of one of the pilot plants burned his hand while attempting to unclog a pipe in a pilot unit at the Chevron Research facility. The employee was transported to the Chevron on-site clinic and later transferred to Brookside Hospital due to nausea. CWS Level 1 was issued. No additional details about the incident were recorded on the CCHS Hazardous Materials Program Incident, Notification, and Complaint Report Form.
- **On October 21, 2002, at 6:00 a.m.,** three 115 kilovolt (kV) flashovers (an unintended electrical arc “flashes over” from one exposed live conductor to another or to the ground, producing intense heat and light) occurred at the Standard Oils Switching Station (SOSS) Bus No. 2. The flashovers caused an upset condition in the high voltage electrical system. Following that, at 7:10 a.m., a single flashover occurred on Bus No. 2 at the SOSS. Six circuit breakers opened and electrical power was lost at both Cogeneration (Cogen) units, as well as power to Substations 1 and 2. Both Cogen units tripped on “flame out” causing a high pressure steam shortage throughout the Facility, and the fluid catalytic cracker shut down. During this event, Substations 2 and 4 continued to supply power to a portion of the Facility. There was no release of hazardous substances to off-site receptors.
- **On January 31, 2002, at 12: 07 p.m.,** a release of H_2S occurred when a process upset occurred at the No. 4 sour gas plant in the Isomax ABU, causing the No. 3 sulfur recovery unit in the Cracking ABU to shut down. These occurrences caused the process gases to be routed to the sulfur recovery unit stack and safety flare in the Isomax and Distillation and Reforming units. Two plant operators in the sulfur recovery unit were exposed to H_2S and natural gas during the restart of No. 3 sulfur recovery unit. The Emergency Management Team responded to the incident and determined that the workers were not harmed and could return to work immediately and that no off-site consequences occurred due to the small size of the release.

APPENDIX 4.13-OCA

Off-Site Consequence Analysis Modeling Parameters and Results Summary

Appendix 4.13-OCA
Project RMP*Comp Inputs and Outputs for Worst Case Scenarios
Chevron Modernization Project
Richmond, CA

Chemical	Ammonia (anhydrous) ^a	Hydrogen	Hydrogen sulfide
CAS #	7664-41-7	1333-74-0	7783-06-4
Category	Toxic	Flammable	Toxic
Scenario	Failure of largest containment of liquid ammonia storage	Failure of Praxair hydrogen plant (total inventory)	Failure of largest H ₂ S gas containment
Method	RMP Guidance, Table 7	RMP*Comp ^{c, d}	RMP*Comp ^{b, d}
Quantity Released (lb)	900	40,000	370
Release Duration (min)	10	Instantaneous	10
Release Rate (lb/min)	90	N/A	37
Mitigation Measures	None	None	None
Topography	Urban	N/A	Urban
Endpoint	150 ppm	1 psi	30 ppm
Basis	ERPG-2	CalARP	ERPG-2
Estimated Distance to Toxic/Flammable Endpoint (mi)	0.9	0.4	0.9
Estimated Distance to Toxic/Flammable Endpoint (km)	1.4	0.6	1.4

Notes:

- a. The ERPG-2 value for Ammonia (anhydrous) was recently updated; this analysis uses the updated value of 150 ppm. The CalARP guidance has not yet been updated to reflect this change.
- b. For Hydrogen Sulfide RMP*Comp runs, ENVIRON used a physical state of liquified under pressure.
- c. For Hydrogen RMP*Comp runs, ENVIRON used a physical state of gas.
- d. Default values in RMP*Comp were used for meteorological data inputs.

Abbreviations:

APPENDIX 4.13-PROG

Modernization Project Reliability Program

Modernization Project Reliability Program

Richmond Refinery

2014 Revision

MODERNIZATION PROJECT RELIABILITY PROGRAM

I. INTRODUCTION

Chevron U.S.A. Inc. (“Chevron”) has proposed this Reliability Program (“Program”) to mitigate potentially significant effects to public safety that might arise from implementation of the Modernization Project at Chevron’s Richmond Refinery. Among other things, the Modernization Project would increase the Facility’s sulfur removal capacity from 600 to 900 long tons per day (LT/d), which has the potential to increase the sulfur level of crude oil blends and gas oils processed by the Refinery. Sulfur is a naturally occurring element in crude and must be removed to produce the end-products processed at the Refinery. The processing of sulfur can lead to corrosion (“sulfidation corrosion”) of piping and equipment, and must be effectively monitored and managed. Sulfidation corrosion is identified as a damage mechanism by *American Petroleum Institute (API) Recommended Practice 571 – Damage Mechanisms Affecting Fixed Equipment in the Refining Industry*.

The Project would increase the sulfur content of crude oil blends and gas oils processed at the Refinery. Therefore, the City of Richmond, with technical support from an independent expert retained by the City and Chevron, undertook a Reliability Analysis to assess the potential for increased risk of damage occurring from the physical, operational, and feedstock changes proposed as part of the Project, including from sulfidation corrosion, and makes recommendations on steps to be taken to mitigate the risks from these changes. The results of this Reliability Analysis are presented in the Modernization Project Environmental Impact Report (EIR), *Appendix 4.13 – Reliability Analysis of Modernization Project Changes* (Reliability Analysis).

The Reliability Analysis makes several general observations and recommendations concerning the Refinery’s overall mechanical integrity program, as well as specific recommendations to monitor and address the potential effects of the Project. Section II of this Program generally describes the actions the Refinery is in the process of implementing to enhance its mechanical-integrity program and overall Refinery safety, which Chevron believes address the general recommendations from the Reliability Analysis.¹ Section III of this Program sets forth the Project-specific recommendations that will be implemented as a result of the Reliability Analysis. Section IV of the Program describes the ongoing regulatory review and reporting obligations committed to in this Program that will ensure that the actions identified in this Program is implemented.

II. GENERAL RECOMMENDATIONS AND REFINERY ACTIONS TO ADDRESS

The Reliability Analysis includes the following five general recommendations (*Appendix 4.13, pp. 123-124*):

¹ While these actions are being developed and implemented throughout Chevron U.S.A. Inc.’s refining system, the discussion focuses primarily on development and implementation at the Richmond refinery.

- **Recommendation:** Chevron should ensure that its organizational communication procedures and work processes incorporate mechanisms by which risk concerns, corrective actions, and recommendations that are identified (e.g., during inspections, turnarounds, audits, PHAs, etc.) by personnel (or contractors) are addressed, reviewed and authorized by management as appropriate, tracked, and closed out, and that the rationale for any decision not to implement a recommendation or corrective action, or otherwise address a risk concern, are clearly documented.
- **Recommendation:** Chevron should further clarify and incorporate into their mechanical integrity program and program documents periodic reviews of work processes, procedures, inspection strategies, etc. to account for physical, operational and organizational changes over time that could affect the assumptions that went into the original decisions. Examples that illustrate this include: (1) periodic reviews of inspection CML densities and placements to ensure that unpredictable damage mechanisms can be detected and (2) reviews of wet H₂S damage risk, based on crude feed constituent changes. Chevron reports that it is developing "asset strategy plans" for each process unit, and that the development of the asset strategy plans will address this recommendation by including review of inspection procedures, working documents, CMLs, and damage mechanisms, and that the asset strategy plans will identify and implement changes needed to each as a result of the review. Whether called an "asset strategy plan" or otherwise included in another safety program (e.g., included as part of the Richmond Industrial Safety Ordinance documentation), Chevron should clarify its implementation tracking process for changes needed as a result of these periodic reviews.
- **Recommendation:** Chevron should leverage its existing infrastructure and technology to lessen the reliance on human interaction in responding to potential risks, including for example Chevron's current pilot project to implement Integrity Operating Windows per the guidelines of the draft API 584 Recommended Practice for the crude unit. Chevron should extend the pilot project to the remaining operating units.
- **Recommendation:** Chevron should review their Positive Material Identification (PMI) Procedure for compliance with API 578, *Material Verification Program for New and Existing Alloy Piping Systems*, based on PMI inspection of equipment and piping during shutdown/ dismantling/disassembly, and make revisions, as warranted, to ensure that Chevron's PMI Procedure conforms to API 578.
- **Recommendation:** Chevron should review and modify their Piping Inspection Procedure to incorporate an engineering review of thickness inspection data with near term "Flag" dates for high risk equipment/piping to assure that the actual minimum thickness associated with the Flag date has either been verified through inspection or, alternatively, the inspection data analyzed with techniques such as a statistical analysis (95% CL or extreme value analysis) to evaluate what risk is involved if the actual minimum thickness was not measured.

Regarding the general recommendations, the Refinery is already implementing numerous actions to enhance safety, resulting in new or improved process safety work processes. Changes have

also been made in the reliability organization to provide more mechanical integrity oversight. Chevron believes these and other actions, described in detail in the EIR, *Chapter 4.13 – Public Safety*, § 4.13.2.4.3.2.2², generally address these recommendations.

For example, the first recommendation calls for Chevron to ensure its organizational communication procedures and work processes adequately identify, track, and close out concerns and recommendations regarding risk. The Refinery is already taking the following actions to enhance organizational communication and competency concerning general and specific mechanical-integrity related recommendations:

- Developing and implementing a new process for additional oversight of general mechanical-integrity related recommendations from industry, Chevron’s Energy Technology Company, and other subject matter experts.
- Development and deployment of an Integrity Threat Process to address inspection recommendations for equipment and piping that could significantly impact safety, or environmental or plant operations, including tracking recommendations by target completion date using the refinery’s MERIDIUM and OERI databases until it is resolved.
- Updating its internal work instructions in 2013 to address inspection results that indicate that equipment or piping will reach “flag” or “alert” thickness prior to the next scheduled turnaround and to include immediate notification of any field measures that indicate a remaining life of one year or less. This update also addresses the last general recommendation above to review and modify the piping inspection procedures.
- Enhancing the requirements for training and competency for leadership, inspections, and technical assessments, including specifically training for determining minimum thickness and fitness for service of individual piping components.
- With regard to turnaround planning, tracking and documenting any decision to defer or not to implement a fixed equipment inspection recommendation to approval by the Refinery Business Manager for the process unit for which the recommendation was made.

Further, the second and third general recommendations provide that Chevron should clarify and modify its mechanical integrity program to, among other things, consider physical, operational and organizational changes over time, and to leverage its existing infrastructure and technology to lessen the reliance on human interaction in responding to potential risks. The Refinery is already implementing enhancements to its mechanical-integrity program. For example:

- The Refinery has added a Fixed Equipment Integrity Manager, who is responsible for developing, implementing, and stewarding the refinery’s Fixed Equipment Integrity program with a goal of achieving zero process safety incidents and improving mechanical availability.
- The Refinery has developed and piloted in its crude unit a Damage Mechanism Review (DMR) process that is consistent with *API 571* and which requires a team of subject

² While these actions are being developed and implemented throughout Chevron U.S.A. Inc.’s refining system, the discussion focuses primarily on development and implementation at the Richmond refinery.

matter experts to review, analyze, and make recommendations concerning damage mechanisms and how to mitigate the effects of damage mechanisms on each process unit. This process has now been made a required element in the Process Safety Management (PSM) process at the refinery for identified process units, and is being undertaken on an ongoing basis.

- The Refinery has piloted in its crude unit a process to create and utilize asset strategy plans for each process unit at the piping circuit level, which will be integrated into the DMR process and will include, among other things, integrity operating windows consistent with draft *API 584 – Integrity Operating Windows* and consideration of process conditions, inspections techniques and frequency, mixing and injection points, and corrosion monitoring locations (CML). These asset strategy plans will be implemented for all processing units on an ongoing basis.

The Refinery reports the status of the above-identified actions to CalOSHA as part of the August 5, 2013 terms of probation described in *Chapter 4.13 – Public Safety* of the environmental impact report, and has also committed to providing quarterly updates to the City pursuant to Mitigation Measure 4.13-CUM-1d. As part of this process, Chevron will work with the County, the City, and its consultants, to ensure that the above-stated general recommendations from the Reliability Analysis have been addressed.

In addition, Chevron will undertake a review of its Positive Material Identification (PMI) Procedure for compliance with API 578, *Material Verification Program for New and Existing Alloy Piping Systems*, based on PMI inspection of equipment and piping during shutdown/dismantling/disassembly, and make revisions, as warranted, to ensure that Chevron's PMI Procedure conforms to API 578.

III. PROJECT RECOMMENDATIONS

The enhanced safety measures described above will provide the foundation for the management of damage mechanisms in the refinery, including sulfidation corrosion, on a go-forward basis. In particular, the damage mechanism review process, the updated PHA process, and development and deployment the asset strategy plans, including integrity operating windows, will be used post-Project for all refinery units to manage risks from all damage mechanisms. In addition to this process, which provides for ongoing evaluation of risks and resulting recommendations, the Reliability Analysis has identified numerous Project-specific recommendations, which Chevron is committing to implement as part of this Reliability Program.

In order to identify Project-related recommendations, the Reliability Analysis assumed certain post-Project operating conditions. The assumptions and analytical method are described more fully in the EIR, Appendix 4.13-REL. The recommendations below, including piping circuit upgrades and installation of additional corrosion monitoring equipment, are tiered to this analysis, meaning that these measures will be implemented well before they would be triggered by actual projected post-Project operations.

A. Schedule and Report on Upgrades to Identified Piping Circuits

The Reliability Analysis for the Modernization Project has identified seventeen (17) piping circuits in the Crude Unit that warrant replacement based on the Reliability Analysis. The Refinery has committed to accelerating the replacement of these circuits during the next scheduled turnaround for the Crude Unit, no later than end-of-year (EOY) 2017, as follows:

Equipment number	Equipment description	Existing Metallurgy	New Material	Replacement Date
0955-002-008	V-1103 Desalted Crude	CS	9 Chrome	EOY 2017
0955-002-014	V-1103 Desalted Crude	CS	9 Chrome	EOY 2017
0955-002-015	V-1103 Desalted Crude	CS	9 Chrome	EOY 2017
0955-002-016	V-1103 Desalted Crude	CS	9 Chrome	EOY 2017
0955-002-017	V-1103 Desalted Crude	CS	9 Chrome	EOY 2017
0955-002-018	V-1103 Desalted Crude	CS	9 Chrome	EOY 2017
0955-002-030	Desalted Crude From E-1165A To F-1100A/B	CS	9 Chrome	EOY 2017
0955-002-031	Desalted Crude From E-1165B To F-1100A/B	CS	9 Chrome	EOY 2017
0955-002-032	Desalted Crude From E-1116's to E-1165C	CS	9 Chrome	EOY 2017
0955-007-009	#4 Sidecut Circ Reflux	CS	9 Chrome	EOY 2017
0955-007-017	#4 Sidecut Circ Reflux	CS	9 Chrome	EOY 2017
0955-009-003	C-1100 Bottoms to F-1160	5Cr	9 Chrome	EOY 2017
0955-012-001	C-1160 Outlet #7 Sidecut	CS	9 Chrome	EOY 2017
0955-012-002	#7 Sidecut	CS	9 Chrome	EOY 2017
0955-013-007	C-1160 OUTLET: #8 Sidecut to E-1188	CS	9 Chrome	EOY 2017
0955-013-008	C-1160 Outlet: #8 Sidecut to C-1160	CS	9 Chrome	EOY 2017
0955-013-009	C-1160 Outlet: #8 Sidecut to E-1114	CS	9 Chrome	EOY 2017

The Reliability Analysis for the Modernization Project has also identified four partial piping and valve replacements in the Crude Unit that warrant replacement based on reasonably foreseeable post-Project operating conditions. The Refinery has committed to accelerating the replacement of these partial components during the next scheduled turnaround for the Crude Unit, no later than end-of-year (EOY) 2017, as follows:

Equipment number	Equipment description	Existing Metallurgy	New Material	Replacement Date
0955-015-002	C-1160 OUTLET to E-1165 A/B/C	9Cr/5Cr/ (2) 10" spool piece and drain valves CS	Replace 5Cr and CS with 9CR; existing 9Cr remains in place	EOY 2017
0955-015-017	K-1165A/B Pump Out	9Cr/5Cr/CS	Replace short 5Cr deadleg immediately off filters with 9 Cr. CS is either free-draining, isolated, or cool wash oil service, so no need to replace because do not see regular service	EOY 2017
0955-019-034	P-1165/A Case Vents to C-1160	SS/CS	CS is downstream of single SS block valve. Upgrade the 3/4" CS pump case vents with SS to double block and bleed design.	EOY 2017
0955-019-017	Pump Vents	9Cr/5Cr/CS	Replace 5Cr with 9Cr and add a second block valve and bleeder. CS component is downstream of 5Cr single block valve; no project impact on CS portion downstream of the valve.	EOY 2017

Chevron shall obtain all required permits for replacement of these piping circuits pursuant to the California Building Standards Code, inclusive of the California Fire Code, and, once the piping circuits are replaced, shall submit copies of closed permits to the Planning Department to demonstrate compliance with this commitment.

B. Installation and Monitoring of Additional Permasense® Monitors on Identified Circuits

Since the beginning of 2013, the Refinery has installed a total of 117 Permasense® probes in the Crude Unit on six piping systems consisting of carbon steel, 5 Chrome, and 9 Chrome materials. Permasense® is the trade name of a type of high-temperature ultrasonic device that is mounted on a pipe or vessel, and penetrates through insulation. It has wireless sensors that provide periodic equipment thickness readings (at variable intervals, but currently set to collect thickness data twice a day) to monitor a system. Due to noise and sensitivity, the technology is limited to longer-term trending (days and months vs. hours) which is appropriate for piping subject to sulfidation conditions with its predictable rates.

The six piping circuits on which the sensors were installed were chosen based on past and anticipated projected future operating conditions. The wireless probes collect pipe wall thickness data while the plant is operating, and are used to monitor corrosion rates. This long-term online monitoring program will be part of the reliability program to ensure safe operation of equipment after the Modernization Project commences operations. Thirteen of these piping circuits with Permasense® monitors installed have been identified for replacement and will be upgraded to 9 Chrome pursuant to the piping circuit upgrades planned as a part of this Reliability Program and the Permasense® monitors will not be reinstalled on these circuits. In addition, as part of the Project, the Refinery will install at least 25 additional Permasense® monitors on carbon steel circuits in the Solvent De-Asphalter (SDA). These sensors are being installed to confirm the predictive model results that there will be little-to-no sulfidation corrosion in the SDA post-Project.

Data from the Permasense® monitors will be utilized in the reporting obligations set forth in section IV below.

C. Crude Unit Recommendations

The operational and feedstock changes contemplated by the Modernization Project, specifically increases in sulfur content of feedstocks, increased hydrogen purity produced by the new hydrogen plant, increased H₂S partial pressures in hydroprocessing plants recycle streams, or potentially higher temperatures in the crude unit based on API gravity ratings, could all contribute to increased damage mechanism activity post-Modernization Project, thereby warranting the implementation of the following preventive measures.

1. Based on the marginal results from the F-1100 radiant tube sulfidation analysis, Chevron should monitor the post-Modernization Project sulfur content being fed to the crude unit and use a 2.0 wt.% sulfur content of feed as a trigger to conduct a review of the F-1100 crude charge furnace to study whether the 5 Chrome radiant tubes are safe to operate until the 2017 shutdown.

2. Chevron's analysis of the atmospheric column furnace F-1100 does not include conclusive evidence as to the present creep/stress-rupture condition of the tubes. Therefore, it is believed that some additional actions are required in order to lower the risk of a creep/stress-rupture or sulfidation failure in a F-1100 tube under post-Modernization Project operating conditions. Acceptable options to lower the risk of heater tube failures include:
 - Furnace F-1100: Option 1, complete all of the following actions:
 - Complete a full internal tube inspection for F-1100 during the 4th quarter 2017 crude unit turnaround using intelligent pigs.
 - Conduct testing on the two currently available, radiant section tubes from the F-1100 Furnace to verify their existing metallurgical, physical and mechanical properties, plus remaining creep life using accelerated Omega creep testing as an input to decide whether the F-1100 furnace should be retubed during the 2017 shutdown.
 - Conduct additional metallurgical, physical, mechanical and Omega creep testing on radiant furnace tube samples to be removed during the 2017 shutdown, depending on the results of the Omega testing planned for the 2012 furnace tube samples.
 - In 2017, replace tubes as needed in F-1100, per Chevron's replacement criteria for furnace tubes. The replacement criteria are based on the minimum furnace tube thickness on the furnace Safety Instruction Sheet and remaining wall thickness collected by intelligent pig data.
 - Install at least three Permasense® continuous monitoring ultrasonic thickness gauge monitors in each of the furnace outlet systems. If the monitors indicate an increase in corrosion rates greater than 5 mpy, review the need for additional mitigation actions.
 - Furnace F-1100: Option 2:
 - Retube the F-1100A/B furnace during the 2017 turnaround with 9Cr or higher alloy tubes.
3. The vacuum column furnace, F-1160, is constructed of 5Cr radiant furnace tubes. The recommended actions for this furnace are as follows:
 - Complete a full internal tube inspection for F-1160 during the 2017 crude unit turnaround using intelligent pigs.
 - In 2017, replace tubes as needed in F-1160 per Chevron's replacement criteria for furnace tubes. The replacement criteria are based on the minimum furnace tube thickness on the furnace Safety Instruction Sheet and remaining wall thickness collected by intelligent pig data.
4. Conduct laboratory analyses to more accurately determine crude and crude blend sulfur speciation and H₂S evolution, which could be used to predict likely crude corrosion rates. Timing: 4Q2015

5. Develop integrity operating windows (IOWs) for critical crude unit operating parameters per the guidelines in the draft version of API 584. 3Q2014
6. The Crude Splitter software is used to predict the distribution of the sulfur in the atmospheric tower sidecut and bottom streams. Verify the Crude Splitter predicted sulfur results with post-Modernization data on the sulfur containing streams within the first year of operation following the implementation of the Modernization project if the trigger points (2.25 wt.% sulfur and 2.75 wt. % sulfur) noted in § IV.A below are reached.
7. Revise the asset integrity plans for the Crude Unit Atmospheric Column Reflux Drum, V-1100, the Stabilizer Column Reflux Drum, V-1190, and the Vacuum Column Overhead Seal Drum, V-1160, to include inspection for Wet H₂S damage. An external Automatic Ultrasonic Testing inspection of representative sections of the "water wet" portions of V-1100, V-1160 and V-1190 vessels should be conducted as a baseline before the start of post-Modernization conditions, then checked externally again approximately one year after the start of the Modernization conditions. In addition, a one-time internal inspection should be conducted of these vessels during the scheduled maintenance turnaround after the start of Modernization conditions, using eddy current or other approved internal inspection techniques per the Chevron Wet H₂S program.
8. Develop a process monitoring plan for the crude unit overhead to confirm any impacts of the increased sulfur levels. The monitoring plan should be implemented post-Modernization and should include:
 - Process sampling of the accumulator for pH, chlorides, iron and H₂S content. Compare to established integrity operating windows (IOWs);
 - Monitor Desalter pH;
 - Analyze the atmospheric tower post-Modernization to quantify if, and how much, increased H₂S is in the overhead system resulting from the increased sulfur feed to the unit;
 - Higher mercaptan crudes could lead to increased sulfidation corrosion rates in the jet or kerosene cuts. Modify asset integrity plans to monitor for potential increased corrosion if higher mercaptan crudes are run compared with current and historical crude and crude blends; and
 - Review the asset integrity plan to ensure that the Permasense continuous ultrasonic monitoring locations are properly placed to ensure early detection should corrosion rates increase significantly beyond expectations per the McConomy curve predicted rates.
9. Develop and implement physical or administrative controls to assure that carbon steel piping components downstream of high sulfur streams operating > 500F are not inadvertently placed into continuous (e.g., placement of a warning tag, locked valve, double-block-and-bleed valves or other measures). This should be completed prior to the commencement of Modernization Project operations.
10. Higher mercaptan crudes could lead to increased sulfidation corrosion rates in the jet or kerosene cuts. Conduct a historical review of purchased crudes and processed crude blends for the 90% confidence level of highest mercaptans processed and use

this statistical number to set a review flag in the crude and gas oil acceptance procedure. If higher mercaptans crudes are run at the Richmond Refinery, review the Permasense® corrosion rate data from this time period as part of the crude management of change lookback. This should be completed prior to the commencement of Modernization Project operations.

11. Add corrosion monitoring locations (CMLs) to the crude unit atmospheric column overhead piping (circuit 0955-003-001) at the termination of the Hastelloy internal overlay. This should include the termination of cladding in the vertical section of piping, as well as the termination point at the inlet to the E- 1101's. Review other, similar locations in the crude unit for missing dissimilar metal interface thickness monitoring locations (TMLs). This should be completed prior to the commencement of Modernization Project operations.

D. Hydroprocessing Recommendations

1. At the 2.25% wt. % sulfur in crude feed trigger point, evaluate and modify as warranted, based on any increased sulfur in this section of the unit, inspection plans (what, where and how often) for the distillation section of the hydroprocessing units where sulfidation corrosion rates have been “erratic” and uncertain, per API 939-C.
2. Report on the progress of the project to compare the HP-002 Best Practice Guideline regarding water wash to API 932-B recommendations to ensure that the HP-002 document is consistent with 932-B guidelines. This report should be submitted prior to the commencement of Modernization Project operations.
3. Conduct process monitoring and sampling for post-Modernization Project operations for all hydroprocessing units, to develop process data to confirm assumptions made during the damage mechanism review regarding amounts of H₂S and ammonium bisulfide in the overhead systems. This shall be completed after commencement of Modernization Project operations.
4. Develop integrity operating windows (IOWs) for the hydroprocessing units to incorporate existing critical reliability variables such as the wash water rate for Nh₄HS corrosion control. The IOWs shall be established prior to the startup of Modernization Project operations.
5. If the REAC Corrosion Control Project (TKN) is not completed pre-Modernization Project, conduct a review of current operations to ensure that corrosion rates will remain under REAC best practice guidelines with any increase in sulfur to the unit. This shall be completed prior to the startup of Modernization Project operations.

E. SDA Recommendations

1. Verify post-Modernization Project conditions regarding H₂S content in the SDA overheads and target one or more “water wet” vessels for inspection using internal eddy current, external automatic ultrasonics (AUT) or other non-destructive evaluation (NDE) techniques appropriate for wet H₂S cracking detection within one year of operation under post-Modernization Project conditions.
2. Conduct water boot analysis for corrosive constituents similar to that conducted in the crude unit on the unit overhead accumulator drums, including cyanides. This should

be conducted at the 2.25 wt.% and 2.75 wt. % sulfur trigger points identified in § IV.A below.

3. When the sulfur wt.% of crude oil processed at the Facility reaches 2.25 wt.% sulfur on an annual average, and the again when it reaches 2.75 wt.% sulfur annual average, the Facility shall trigger the same responses for the SDA plant as described in the recommendation section for the crude unit.
4. Conduct a follow-up smart pig inspection of F-100 and F-120 furnace tubes during the first planned maintenance after the unit has seen at least 1 year of post-Modernization Project operating conditions.
5. Install at least 25 additional Permasense® monitors on carbon steel circuits in the Solvent De-Asphalter (SDA) including sulfidation “dead legs,” based on a critical review of historical corrosion rates. These sensors will confirm the predictive model results that there will be little-to-no increase in sulfidation corrosion in the SDA post-Modernization Project. These installations should be completed prior to the commencement of Modernization Project operations.
6. Develop integrity operating windows (IOWs) per draft API RP-584 for identified damage mechanisms in the SDA unit. The IOWs should be established prior to the commencement of Modernization Project operations.
7. Develop process monitoring and sampling plans for post-Modernization Project operating conditions to confirm assumptions made during the damage mechanism review project. The monitoring and sampling plans should be developed prior to the commencement of Modernization Project operations, and should be implemented after commencement of Project operations following an increase in sulfur content to the SDA unit.

F. Amine Systems Recommendations.

It is recommended that Chevron review ongoing sampling results (per Best Practice timing plus vendor sampling and reports) to determine if post-Modernization Project amine loading and heat stable amine salts (HSAS) are impacted by any increase in H₂S to the TKC Unit. This should be done prior to the commencement of Modernization Project operations.

G. Sulfur Recovery Unit Recommendations

Associated with the new liquid oxygen piping, the Facility shall typically design and build new construction in conformance with the special design and installation precautions associated with oxygen piping systems, i.e., design and installation best practice details common in industry for oxygen piping systems, including pre-commissioning cleaning of the piping interior to remove harmful materials such as dirt, debris, iron, grease and other contaminants known to cause ignition of pure liquid and gaseous oxygen.

H. Sour Gas System Recommendations

Based on the potential risk of ammonium bisulfide corrosion in carbon steel due to the possibility of the sour gas condensing at locally cool portions of piping, Chevron should develop and implement a mitigation plan for this eventuality. The mitigation plan is to

include reviewing sour gas P&IDs and isometric drawings to locate low points where water could accumulate, locate dead legs and establish inspection/monitoring plans for verifying if and where water is condensing out of the vapor phase. This should be conducted within 1 year of commencement of Modernization Project start-up.

1. Chevron should conduct a review to confirm their post-Modernization assumptions made during this review regarding ammonium bisulfide concentrations, dew points and potential for salt condensation in the sour gas piping, at the 2.25 wt. % and 2.75 wt. % average annual sulfur content trigger points.
2. Develop integrity operating windows (IOWs) per draft API RP-584 for identified damage mechanisms for the sour gas system. These IOWs should be established prior to the commencement of Modernization Project operations.

I. Sour Water System Recommendations

1. The block diagrams shown in Figure A4.13-REL-16 and Figure A4.13-REL-17 do not include detailed information at the “P&ID” level. Also, information is lacking on the sour gas streams in the overhead of the H₂S and NH₃ strippers in the SWS unit. (However, for purposes of the review the overhead systems of the WWT plants were deemed to be out of scope.) The impact of post-Modernization Project corrosion from sour water corrosion should be minimal, based on the Reviewer’s analysis of the sour water streams. However, based on a lack of detail at the P&ID level Chevron should conduct a review of their sour water piping inspection programs at the P&ID/Inspection Isometric level (including to ensure that low points, galvanic metal couple locations and CMLs are properly captured) to ensure that their program is sufficient to detect any ammonium bisulfide corrosion in the system. This should be completed prior to the commencement of Modernization Project operations.
2. Chevron should be monitoring and sampling to confirm their assumptions regarding the ammonium bisulfide concentrations and velocities in the sour water piping and H₂S concentrations in the H₂S Stripper and NH₃ Stripper overhead systems. This review should be conducted when average annual sulfur content levels reach 2.25 wt. % and again at 2.75 wt. %.
3. The H₂S stripper, NH₃ stripper, ammonia stripper overhead condenser, and ammonia stripper reflux drum are all Category 2 Wet H₂S vessels and therefore are included in Chevron’s wet H₂S program. If a post-Modernization Project review of the assumptions regarding the severity of wet H₂S damage in the overhead systems warrants a change in the categorization of the overhead wet H₂S vessels, then a wet H₂S cracking inspection should be conducted. This should be conducted within one year after the commencement of Modernization Project operations.
4. Continue as with the existing condition inspection, the X-ray and/or close-grid UT inspection techniques for all of the overhead piping from the NH₃ stripper to the reflux drum regardless of metallurgy.
5. Develop integrity operating windows (IOWs) per draft API RP-584 for identified damage mechanisms for the sour water system. The IOWs should be established prior to the commencement of Modernization Project operations.

J. Recovered Oil Recommendations

If not already present, add CML locations to the C-710 injection nozzle and adjacent C-710 tower shell so that the assumptions regarding post-Modernization Project corrosion rates not increasing in severity can be verified. Implement prior to the operational startup of the Modernization Project.

IV. ONGOING REGULATORY REVIEW AND REPORTING

In order to demonstrate compliance with the recommendation above, as well as to provide the City regular update concerning the implementation of the corrective actions described in § II above, the Refinery will undertake the following reporting obligations.

A. Re-evaluate and Report on Post-Project Operating Assumptions from Reliability Review

The Reliability Analysis for the Modernization Project assumed certain operating conditions once the Project is implemented, including projected temperatures, sulfur levels, and corrosion rates for various process units and individual piping circuits. These assumptions were based on a conservative 3.3 wt% sulfur case. In order to verify that the assumptions made during the reliability review were accurate, the Refinery will undertake the following actions:

- When the sulfur weight percent of crude oil processed at the Refinery reaches 2.25 wt% sulfur on an annual average, and the again when it reaches 2.75 wt% sulfur annual average, the Refinery shall:
 - Assemble a reliability review team that will be made up of appropriate subject matter experts (SMEs), including a Senior Process Engineer, Senior ETC Materials and Corrosion Engineer, Refinery Materials Engineer and Process Operator.
 - For all damage mechanisms identified as being affected by the Project, and using then-current inspection and/or monitoring data, the reliability review team shall review, analyze, and, as necessary, update, the data and conclusions prepared during the reliability review for the Modernization Project to determine whether the assumptions made and conclusions reached during the reliability review accurately reflect actual post-Project operating conditions.
 - Use the data from the laboratory tests described above to consider any potential post-Project impacts from sulfur speciation.
 - Review any operational or process changes that have occurred post-Project.
 - Make recommendations concerning material upgrades and /or enhanced inspection opportunities as necessary based on the re-evaluation.
 - Report on the results of the this re-evaluation and any resulting recommendation to Contra Costa Health Services, the expert agency charged with implementing the Richmond Industrial Safety Ordinance, as well as one or more Refinery workforce representatives from any process units impacted by the re-evaluation and recommendations and who shall have the necessary subject matter expertise to engage in a Project-level reliability review.

B. Report Inspection Results for Identified Circuits in Service Susceptible to High-Temperature Sulfidation Corrosion and other Damage Mechanisms Effected by the Project

All piping circuits in the Refinery, including the new 9 Chrome circuits being installed pursuant to § III.A of this Reliability Program, are regularly monitored and inspected. Beginning one year from commencement of Project operations, and annually thereafter, the Refinery will provide reports to the City summarizing the monitoring and inspection results for the identified circuits. These reports shall at a minimum include the following information:

- A list of all piping circuits identified as potentially susceptible to sulfidation corrosion, including specifically piping circuits identified during the reliability review for the Modernization Project as being susceptible to sulfidation corrosion and subject to potential process changes.
- A list of components identified through the 100% component inspection conducted following the August 6, 2012 incident pursuant to the methodologies set forth in the API 939-C - Guidelines for Avoiding Sulfidation (Sulfidic) Corrosion Failures in Oil Refineries and Updated Inspection Strategies for Preventing Sulfidation Corrosion Failures in Chevron Refineries (Sept. 30, 2009) that may lack sufficient thickness to remain in service until the next scheduled turnaround.
- A description of the solutions implemented with respect to components of insufficient thickness identified above.
- A description of the current fixed inspection frequency for carbon steel piping circuits identified as potentially susceptible to sulfidation corrosion.
- A description of any findings from inspection and monitoring of the piping circuits identified during the reliability review for the Modernization Project as being susceptible to sulfidation corrosion and subject to potential process changes that indicate that any of these circuits lack sufficient thickness to remain in service until the next turnaround and a description of the solution to be implemented with respect to these circuits.
- Chevron shall obtain all required permits for replacement of these piping circuits pursuant to the California Building Standards Code, inclusive of the California Fire Code, and, once the piping circuits are replaced, shall submit copies of closed permits to the Planning Department to demonstrate compliance with this commitment.

C. Process Hazard Analyses (PHA) Revalidation

Chevron shall work with Contra Costa Health Services (CCHS) to update and revalidate the process hazard analyses (PHA) prepared for the Project components consistent with the requirements of the Richmond Industrial Safety Ordinance (Richmond Municipal Code Ch. 6.43). This revalidation shall occur prior to commencement of Project construction, and again after construction but before startup of Project operations for any changes that may have arisen during construction that could affect the earlier PHA. The PHAs shall include inherently safer

systems analyses (ISSAs), damage mechanism reviews and evaluation of the consequences thereof resulting from the Project, and Layers of Protection Analyses (LOPA).

Chevron will notify CCHS and the City of the availability of these PHAs, and make these PHAs available for review by CCHS. The PHAs (initial and updates/revalidations, inherently safer systems analysis, damage mechanisms review, and LOPAs) shall be consistent with proposed amendments to the RISO. Chevron shall conduct the LOPAs and submit written LOPA reports, prepared in accordance with industry best practices (such as those issued by the Center for Chemical Process Safety (CCPS)) to CCHS for review prior to construction (and post-construction, for those LOPAs warranted based on changes that arise during construction).

D. Share Schedule for and Report Results of Process Hazard Analyses (PHAs) Considering Damage Mechanisms.

Chevron shall provide annual reports to the City summarizing the PHAs/revalidated PHAs completed during the preceding calendar year to account for consideration of damage mechanisms, and shall include a list of fixed equipment inspection recommendations submitted for each turnaround, indicating which recommendations were accepted, and for those that were not accepted, the reason the recommendation was rejected. All PHAs shall be available for agency review pursuant to the terms of the RISO.

E. Updated Safety Program List

Chevron shall maintain a list of programs, procedures, and/or other Refinery documentation that are updated to implement this Reliability Program or the corrective actions described in § II above. Chevron shall maintain this list at the Refinery and make it available to the County during audits, inspections, or upon request.

F. Other Reporting Obligations

1. Probation Terms Reporting

Prior to Project start-up, Chevron shall provide the City a status report on the refinery's compliance with the terms of probation entered into on August 5, 2013, and shall thereafter provide the City reports substantively similar to the reports filed with Cal/OSHA under the terms of probation once per year as necessary until such time as the terms of probation end, including a copy of any response documents provided by CalOSHA, or a detailed summary of any CalOSHA responses if CalOSHA does not approve sharing the response documents with the City. Chevron will work with CalOSHA to pursue their approval to share the Chevron CalOSHA response documents. The original reports and related documents shall be made available at the Refinery upon request by the City or County and during any audits or inspections conducted under the RISO.

2. RISO Audits

Following commencement of Project operations, Chevron shall provide the City an annual report informing the City of any agency-initiated audits performed pursuant to the Richmond Industrial Safety Ordinance during the previous calendar year, and shall update the City concerning the findings from and status of implementation of any recommendation that come out of such audits.

G. Community Engagement

On an annual basis following Project approval until such time as the City determines that such meetings are no longer required, Chevron shall hold town halls for its workforce and for the community to provide updates concerning:

1. The status of the enhanced safety measures being implemented by the Refinery following the August 6, 2012 fire, including actions taken to implement the recommendations made by public agencies that investigated the August 6 incident.
2. The status and/or results of the material upgrades, inspection and monitoring program, and ongoing compliance with the Richmond Industrial Safety Ordinance, including Project-related PHAs, DMRs, LOPAs, and ISSAs.
3. When triggered, the results of the reliability review revalidation and the status of any recommendations made as a result of this review.

H. Reporting Obligation

As part of its ongoing reporting obligation under the Mitigation Monitoring and Reporting Program adopted by the City, Chevron shall report on the status of all requirements of this Reliability Program on an annual basis in a form acceptable to the City. All reporting obligations herein shall be subject to the protection for trade secrets provided in Richmond Municipal Code § 6.43.110 and California Health and Safety Code section 25538 incorporated therein.

APPENDIX 4.13-REL

Reliability Analysis of Modernization Project Changes

March 7, 2014

ENVIRON International Corporation
201 California Street, Suite 1200
San Francisco, CA 94111

Attn: Dr. Douglas Daugherty
Re: Reliability Analysis

Dear Dr. Daugherty:

The Hendrix Group In. (Hendrix) was engaged by Environ, on behalf of the City of Richmond (City), to provide refinery technical expertise to the City of Richmond for the development of an environmental impact report (EIR) for the Chevron Richmond Revised Renewal Project (Modernization Project).

Hendrix was asked to conduct a Reliability Analysis to support the City's assessment of hazard risk potentially resulting from operational and feedstock changes associated with the Modernization Project for the Environmental Impact Report being prepared for this Project. The Reliability Analysis included a review of Chevron documentation (including confidential business information), as well as extensive interviews with Chevron personnel and subject matter experts.

The technical report describing our Reliability Analysis, including conclusions and recommendations, is attached to this letter.

Sincerely,
David Hendrix, Principal
The Hendrix Group, Inc.

APPENDIX 4.13-REL

RELIABILITY ANALYSIS OF MODERNIZATION PROJECT CHANGES

1.1 OVERVIEW

Refinery Operations include processing flammable crude and gas oils in various process units that involve heat, pressure, and chemical reactions. Refinery Operations also require storage and internalized pipeline transportation of petroleum and other hazardous materials. As discussed in the EIR, *Section 4.13, Public Safety*, in recent years two refinery fires at the Chevron Richmond Refinery (Facility) have resulted from pipeline corrosion, attributable at least in part, to processing higher concentrations of sulfur in high-temperature Refinery Operations—i.e., high-temperature sulfidation (HTS). This is one type of “damage mechanism” that is known to occur in refineries, based on their operations, but there are other known mechanisms that can also cause damage to refinery equipment. This technical appendix provides background on how damage can occur from the operation of a refinery, assesses the potential for increased risk of damage occurring from the physical, operational, and feedstock changes proposed as part of the Modernization Project, and makes recommendations on steps that can be taken to reduce the risks from these changes.

“Damage mechanisms” are those phenomena that cause the degradation of materials, based on exposure to their environment. For the purposes of this report, the damage mechanisms include those corrosion processes, cracking mechanisms, and mechanical and metallurgical changes to a material that result in a loss of function or a pressure boundary release to atmosphere.

1.2 SCOPE AND METHODOLOGY

The City of Richmond retained the author of this report—a refinery corrosion expert (Reviewer)—to conduct a reliability analysis (Reliability Analysis) to identify and evaluate the risks that may result from Modernization Project operational and feedstock changes.¹ The Reliability Analysis was not limited to the new and modified units associated with the Project. The Reliability Analysis considered all units, process, and ancillary equipment at the Facility that may be affected by Modernization Project operational and feedstock changes. Units and equipment that would not be affected physically, operationally, or from changing

¹ The potential risks associated with the physical changes of the Modernization Project are outside the scope of this Review and are analyzed in the EIR, *Section 4.13, Public Safety*.

characteristics of crude and gas oils associated with the Modernization Project were identified and eliminated from further reliability analysis.

The methodology for this Reliability Analysis was based on an approach whereby the Reviewer and City's technical consultants conducted interviews with and reviewed information provided by Facility and Chevron Technical Department subject matter experts (SMEs) from several technical disciplines including Process Engineering, Technical Department Materials and Equipment Engineering, and refinery Materials Engineering personnel, with support from other departments, as needed. Based on discussions and interviews with Chevron personnel and review of relevant documents, the methodology for conducting the Review for the Modernization Project included the following steps:

1. Determine the post-Modernization Project operating conditions;
2. Identify the potential damage mechanisms that would result from the Modernization Project operating conditions, and identify the units and equipment that potentially would be impacted by these damage mechanisms;
3. Evaluate the potential impact of the identified damage mechanisms on fixed equipment, piping, and piping components under post-Modernization Project operating conditions; and
4. Recommend measures to reduce the potential impacts of new or increased damage mechanism activity that could result from the Modernization Project.

The first step in the Reliability Analysis—identifying the post-Modernization Project operating conditions—was accomplished by conducting interviews with Chevron SMEs and collecting and reviewing relevant documentation containing information on process temperature and pressure changes, Modernization Project physical changes, changes in crude and gas oil sulfur content, increases in Hydrogen Sulfide (H_2S) and ammonium bisulfide in sour water and sour gas streams and process monitoring tools. The Reliability Analysis identified the following Modernization Project changes in operating parameters and feedstock characteristics relevant to the damage mechanism evaluation:

- Increased sulfur content (wt. %) in feedstocks (crude and gas oils);
- Increased hydrogen (H_2) purity (partial pressure) produced from a new hydrogen plant;
- Increased H_2S partial pressures in refinery processing units where the sulfur in the crude is either intentionally, or as a by-product of other reactions, converted to other sulfur containing compounds;

- Increase in nitrogen content based on a moderate to strong statistical relationship found between API gravity in the intermediate-light gravity range (between 28 and 40 API) and nitrogen content and a weak correlation between sulfur and nitrogen content as described in Appendix 4.3-MET; and
- Increased ammonium bisulfide content of high severity hydroprocessing/sour gas streams based on the sensitivity analysis for nitrogen at 1877 ppm.

Increased Facility operational utilization from 89% up to 93% and possibly to 100% of Title V permitted levels was also evaluated in the context of damage mechanism activity. However, because impacts from damage mechanisms are estimated based on “full utilization” (i.e., constant exposure to the environmental factor causing the degradation), changes in utilization were considered to be negligible for purposes of evaluating risk.

For purposes of analyzing the characteristics of different crude oil blends and gas oils that might be processed at the Facility in post-Modernization Project operating conditions, and the risks associated with those different feedstocks, the Review considered two theoretical crude oil blends. First, the Review identified a benchmark crude analytical case—referred to as the “P-50” case—representing a crude oil blend with approximately 2.38 wt. % sulfur and 32.3 API gravity.² In addition, this Review evaluated an analytical “P-90” case, representing a crude oil blend with approximately 3.28 wt. % sulfur and 28.4 API gravity.³

While the P-50 case is representative of reasonably foreseeable Modernization Project conditions, the P-90 case represents an extreme scenario that is not likely to materialize in post-Modernization Project operating conditions. The Reviewer was provided information indicating that the Facility would not likely be able to process a crude blend similar to the P-90 case due to other Facility constraints, such as the sulfur removal capacity limitation and permitted capacity of units such as the solvent de-asphalting unit (SDA unit). These constraints would likely require decreasing the Facility's utilization rate when the sulfur content of feedstocks increases.

Temperature was discussed and determined not to be a variable changing as a result of the Modernization Project. Therefore, it is not included in this Reliability Analysis, other than in the context of its ongoing role in damage mechanisms already present in baseline operating conditions such as high temperature sulfidation.

² This P-50 case roughly approximates the URM “project crude blend” of 31.6 API gravity and 2.5 wt. % sulfur identified in Appendix 4.3-URM for purposes of the air quality impacts analyzed by the EIR.

³ The characteristics of this P-90 case generally correspond to the “heaviest crude blend” and the “most sour crude blend” cases in Appendix 4.3-URM.

Finally, because the Modernization Project may result in a slight decrease in crude oil gravity post-Project, and because gravity and nitrogen have been found to correlate in Appendix 4.3-MET, this Reliability Analysis evaluated a conservative scenario of processing a crude oil blend with 1877 ppm nitrogen. Chevron was unable to identify a crude blend in the intermediate-light gravity range that approximated the 1877 ppm nitrogen number, so instead conservatively increased the 1596 ppm nitrogen level of a crude blend used in Appendix 4.3-URM with 30.3 API gravity and 2.35 wt% sulfur. Given the need to artificially increase the nitrogen level of the crude blend for analytical purposes, it is not reasonably foreseeable that such high-nitrogen blend would be processed post-Modernization Project due to design constraints that limit the Facility's ability to process crudes outside of the intermediate-light gravity range on a sustained basis.

The specific methods by which the Reviewer determined which process units and associated equipment and piping may be impacted by Modernization Project are discussed in detail in subsequent sections. The primary basis for the identification of damage mechanisms that might be implicated by the Modernization Project was consideration by the Reviewer of *API-571 - Damage Mechanisms Affecting Fixed Equipment in the Refining Industry*. In addition, the Reviewer relied on his extensive experience in refinery damage mechanisms to identify additional damage mechanisms that are not listed in *API-571* for evaluation as a part of this Reliability Analysis. Additional details regarding the identification of damage mechanisms for purposes of this Reliability Analysis are included in subsequent sections of this Appendix.

1.3 BACKGROUND ON DAMAGE MECHANISMS IN REFINERY OPERATIONS

1.3.1 General Description of Hazards Associated with Refinery Operations

Crude oil is a complex mixture of thousands of different hydrocarbons and varying amounts of other compounds containing sulfur, nitrogen, and oxygen, as well as salts, trace metals, and water. Crude oils can vary from a clear liquid, similar to gasoline, to a thick, tar-like material needing to be heated to flow through a pipeline. A petroleum refinery's main function is to split crude oil into its many parts (or fractions) which are then reprocessed into useful products. The type, number, and size of process units required at a particular refinery depends on a variety of factors including the type of crude oil and the products required. The interconnected units making up a refinery are a maze of tanks, furnaces, distillation towers (fractionating columns), reactors, heat exchangers, pumps, pipes, fittings, and valves, as well as control systems, instrumentation, and safety equipment. Products of crude oil refineries include:

- Fuels such as gasoline, diesel fuel, heating oil, kerosene, jet fuel, bunker fuel oil, and liquefied petroleum gas;
- Petroleum solvents including benzene, toluene, xylene, hexane, and heptane, which are used in paint thinners, dry-cleaning solvents, degreasers, and pesticide solvents;
- Lubricating oils produced for a variety of purposes, and insulating, hydraulic, heat transfer and medicinal oils;
- Petroleum wax;
- Greases, which are primarily a mixture of various fillers; and
- Asphalt.

These products can be hazardous not only in their final state but also as they are being processed and refined.

1.3.2 Health and Safety Hazards

The plant and equipment of refineries are generally modern, and the processes are largely automated and totally enclosed. Routine operations of the refining processes generally present a low risk of exposure when adequate maintenance is carried out and proper industry standards for design, construction, and operation have been followed. The potential for hazardous exposures always exists, however.

1.3.3 Hazardous Chemicals

In a refinery, hazardous chemicals can come from many sources and in many forms. In crude oil, there are not only the components intended for processing, but impurities such as sulfur, chlorides, water, vanadium, and arsenic compounds. The oil is separated into many component streams that are further altered and refined to produce the final product range. Most, if not all, of these component stream chemicals are inherently hazardous to humans, as are the other chemicals added during processing. Hazards include fire, explosion, toxicity, corrosiveness, and asphyxiation.

1.3.4 Fire and Explosion

The principal hazards at refineries are fire and explosion. Refineries process a multitude of products with low flash points (i.e., the temperature at which there is sufficient vapor of a given chemical to ignite when an ignition source is present). Although systems and operating practices are designed to prevent such catastrophes, they can occur. Constant monitoring is therefore required.

Safeguards include warning systems, emergency procedures, and permit systems for any kind of hot or other potentially dangerous work.

1.3.5 Airborne Exposure

Airborne exposure can occur with a release of a substance from the Facility that is acutely hazardous, such as ammonia, H₂S, or any harmful byproducts which may occur from a fire. A release can be a threat if a harmful concentration of the gas reaches off-site receptors.

Table A4.13-REL-1 highlights major potential air contaminants which can escape from a typical refinery operation and their major sources. It does not attempt to identify all such possible hazards.

Table A4.13-REL-2 reviews common hazardous chemicals and chemical groups typically present and their most significant hazards to workers.

1.3.6 Major Shutdown and Maintenance

The principal exposures to hazardous substances occur during shutdown or maintenance work, since these are a deviation from routine operations. Facility turnarounds require careful planning, scheduling, and step-by-step procedures to make sure that unanticipated exposures do not occur.

1.3.7 General Description of How Refineries Manage Risks from these Hazards

1.3.7.1 Process Safety Programs

There are a host of procedural/prescriptive and performance based publications, guidelines, recommended practices and standards/laws on process safety promulgated by industry, standards writing organizations, industrial advocacy groups and governmental organizations on a federal, State and local level. Many, if not most of them, originate from the OSHA "Process Safety Management of Highly Hazardous Chemicals" regulations, which contain requirements for the management of hazards associated with processes using highly hazardous chemicals to help assure safe and healthful workplaces. The regulations include various performance based requirements related to process safety that the refining industry is obligated to meet and those specific requirements are listed elsewhere. Included in the requirements is a mechanical integrity section that stipulates the requirements for maintaining the mechanical integrity of process equipment.

The mechanical integrity requirements include the following elements:

- The employer must establish and implement written procedures to maintain the ongoing integrity of process equipment;

TABLE A4.13-REL-1 MAJOR POTENTIAL AIR CONTAMINANTS WHICH CAN ESCAPE FROM A TYPICAL REFINERY OPERATION AND THEIR MAJOR SOURCES

Air Contaminants	Major Sources
Hydrocarbon vapors – compounds of carbon (C) and hydrogen (H)	▪ transfer and loading operations ▪ storage tanks ▪ crude unit, atmospheric, and vacuum towers ▪ cracking units (“cat”, hydrocracking, coking-polynuclear aromatic hydrocarbons [PAHs] and high-boiling aromatic hydrocarbons [HBAHs] are of concern because of their carcinogenic potential) ▪ rearranging and combining processes such as reformers and alkylation units ▪ treating operations ▪ cracking unit regeneration ▪ heat exchangers ▪ boilers and heaters ▪ pumps, valves ▪ cooling towers
Sulfur dioxide (SO ₂)	▪ boilers ▪ cracking unit regeneration ▪ treating operations ▪ flares
Carbon monoxide (CO)	▪ rearranging and combining processes such as reformers and alkylation units ▪ catalyst regeneration ▪ flares ▪ boilers ▪ furnaces
Nitrogen dioxide (NO _x)	▪ flares ▪ boilers
Hydrogen sulfide (H ₂ S)	▪ sour crudes ▪ liquid wastes ▪ pumps ▪ crude tower ▪ cracking operations ▪ rearranging and combining processes such as reformers and alkylation units ▪ hydrogenation
Particulates	▪ catalyst dusts – cracking units, catalyst regeneration, and rearranging and combining processes such as reformers and alkylation units ▪ petroleum coke dust – cracking units
Chlorine (Cl or Cl ₂)	▪ caustic unit
Ammonia (NH ₃)	▪ compressors

**TABLE A4.13-REL-2 COMMON HAZARDOUS CHEMICALS AND CHEMICAL GROUPS
TYPICALLY PRESENT AND THEIR MOST SIGNIFICANT HAZARDS TO
WORKERS**

Material	Dominant Hazard
Additives	▪ usually skin irritants
Ammonia	▪ designated substance under construction regulations. See chapter on asbestos in this manual.
Asphalt	▪ dermatitis (can be photosensitizer)
Benzene	▪ designated substance under industrial regulations
Carbon monoxide	▪ toxic on inhalation
Caustic soda	▪ corrosive to skin and eyes
Chlorine	▪ corrosive to skin and tissue on contact or inhalation
HBAHs (high boiling aromatic hydrocarbons)	▪ potential carcinogens
Hydrofluoric acid	▪ corrosive to skin and tissue on contact or inhalation
Hydrogen sulphide	▪ toxic on inhalation
MEK (methyl ethyl ketone)	▪ corrosive to skin
Nitrogen	▪ asphyxiant
PAHs (polynuclear aromatic hydrocarbons)	▪ potential carcinogens
Phenol-acid	▪ corrosive to skin and tissue
Silica	▪ designated substance under industrial regulations
Sulphuric acid	▪ corrosive to skin and tissue on contact or inhalation
Sulphur dioxide	▪ toxic on inhalation

- Employees involved in maintaining the ongoing integrity of process equipment must be trained in an overview of that process and its hazards and trained in the procedures applicable to the employees' job tasks;
- Inspection and testing must be performed on process equipment, using procedures that follow recognized and generally accepted good engineering practices (RAGAGEP);
- The frequency of inspections and tests of process equipment must conform with manufacturers' recommendations and good engineering practices, or more frequently if determined to be necessary by prior operating experience;
- Equipment deficiencies outside the acceptable limits defined by the process safety information must be corrected before further use;

- In constructing new plants and equipment, the employer must ensure that equipment, as it is fabricated, is suitable for the process application for which it will be used. Appropriate checks and inspections must be performed to ensure that equipment is installed properly and is consistent with design specifications and the manufacturer's instructions;
- The employer also must ensure that maintenance materials, spare parts, and equipment are suitable for the process application for which they will be used.

It is the above mechanical integrity elements that go to the heart of minimizing the release of hazardous substances due to equipment failure from the various damage mechanisms discussed in this Appendix. Various industry organizations and standards writing organization have published various documents intended to define minimum requirements for the OSHA Mechanical Integrity performance base elements, primary among them The American Petroleum Institute (API). In turn, refining organizations have drafted internal mechanical integrity procedures and guidelines intended to satisfy the regulations within their specific organizational structure and experience.

1.3.7.2 Management of Change

Management of change (MOC) involves: (1) the recognition of change situations; (2) the evaluation of hazards; (3) the decision on whether to allow a change to be made; and, (4) necessary risk control and follow-up measures (CCPS, 2014). The MOC element helps ensure that changes to a process do not inadvertently introduce new hazards or unknowingly increase risk of existing hazards. The MOC element includes a review and authorization process for evaluating proposed adjustments to facility design, operations, organization, or activities prior to implementation to make certain that no unforeseen new hazards are introduced and that the risk of existing hazards to employees, the public, or the environment is not unknowingly increased. It also includes steps to help ensure that potentially affected personnel are notified of the change and that pertinent documents, such as procedures, process safety knowledge, and so forth, are kept up-to-date.

Organizations usually have written procedures detailing how MOC will be implemented. Such procedures apply to all work that is not determined to be Replacement in Kind (RIK). The results of the review process are typically documented on an MOC review form. Supplemental information provided by system designers to aid in the review process is often attached to the MOC review form. Once the change is approved, it can be implemented. Potentially affected personnel are either informed of the change or provided more detailed training, as necessary, prior to implementation of the change. Follow-on activities, such as updates to affected process safety information and to other

Risk Based Process Safety Management (RBPS) elements, are assessed to identify which are required before startup, and which may be deferred until after startup. All such activities are tracked until completed.

1.3.7.3 Inspections/Monitoring

Included in the mechanical integrity section of the OSHA Process Safety Management (PSM) regulations are requirements for inspecting processing equipment to verify its existing condition, based on damage mechanisms that could result in a release to the environment. The inspection and testing must be performed on process equipment using procedures that follow RAGAGEP and the frequency of inspections and tests of process equipment must conform with manufacturers' recommendations and good engineering practices, or based on prior operating experience. The inspections must satisfy the requirements of: (a) being able to identify and locate the damage mechanisms before they result in a release or otherwise compromise the integrity of the equipment and (b) accurately verify their severity. Again, there are many published guidelines, recommended practices and standards that are available to guide the development of an effective inspection program, including API-653,-570, -572, -574, -510 and -580, among others.

Process monitoring is another common tool used by industry to guard against equipment failure. Process monitoring as a mechanical integrity tool is being elevated by the impending issue of a new API document, RP 584. RP 584 is an API Recommended Practice pending publication that outlines the essential elements in defining, monitoring and maintaining integrity operating windows (IOWs) as a vital component of inspection planning, including Risk Based Inspection (RBI) planning. It is intended to address the issue that, however well founded and well managed, inspection and mechanical integrity systems alone cannot maintain the integrity of pressure equipment in and of themselves. API-584 IOWs are discussed further in *Section 1.3.7-5* below.

1.3.7.4 Materials Selection

Damage mechanisms are those phenomena that cause the degradation of materials, based on exposure to their environment. Damage mechanisms result from the natural consequence of exposing processing equipment to the process environment, including hazardous and corrosive chemicals that cause loss of thickness from corrosion, environmental cracking, metallurgical deterioration from exposure to elevated temperatures and mechanical damage. The first line of defense against the failure of equipment (based on a pressure boundary release) from these damage mechanisms is the proper selection of materials known to be resistant to damage mechanisms associated with the process. In the refining industry, there is an extensive body of knowledge regarding the damage mechanisms present in various refining processes and also what metals and/or alloys are known to be resistant to the damage mechanisms at hand. Typically,

this materials selection occurs during the detailed design phase of a new capital project or as a result of a non-capital project maintenance need. Most materials selections involve compromises with the selection decision based on imperfect information regarding the process and economic constraints. The selection also recognizes the issue of planned obsolescence based on an established design life for the project or equipment item. Materials selection can be made by people with various responsibilities and experience backgrounds, but ideally an experienced corrosion and materials engineer is involved in the selection process.

1.3.7.5 Integrity Operating Windows

In addition to the application of industry codes, standards and recommended practices, a number of other systems are vital to support a rigorous mechanical integrity program in order to predict/avoid/prevent pressure equipment damage/corrosion, leaks and failures and improve reliability. Three key elements of those systems as described in the draft API RP 584, Integrity Operating Windows, include:

1. The establishment, implementation and maintenance of IOWs;
2. An effective transfer of knowledge about unit specific IOWs to all affected personnel; and
3. An effective MOC program to identify any changes to the process or the physical hardware that might affect the integrity of pressure equipment.

Chevron has stated that it is currently in the process of establishing IOWs for the crude unit, per the draft API-584 Integrity Operating Windows, and is expected to complete implementation in the crude unit 3Q 2014. Some IOWs for the crude unit have already been determined through an SME review process. One example of an IOW would be the process temperature limit at the top of the atmospheric tower that Chevron attempts to control above the salt dew point temperature limit. Chevron's Best Practice (Crude Unit Overhead Corrosion Control Best Practices) calls for a minimum 25F margin between the atmospheric tower overhead process temperature and the temperature at which chloride salts form. A review of Chevron's IOWs that have been established shows that this particular IOW is included. In addition, Chevron has stated that the newly established IOWs per API-584 will be integrated with the existing refinery process monitoring (RPM) work process as discussed above. This will allow for:

- Integrating with an established work process
- Roles and responsibilities per API-584
- Notification process when IOWs are in deviation

Chevron is in the process of implementing a formal IOW program that meets the requirements of the draft API recommended practice. This will expand upon their existing critical reliability variables. For the third element Chevron has a mature MOC program. In order to operate any process unit, a set of operating ranges and limits needs to be established for key process variables, to achieve the desired results (i.e., product within specification, safe operation, reliability, etc.). These limits are generally called operating limits or operating envelopes. IOWs are a specific subset of these key operating limits that focus only on maintaining the integrity or reliability of process equipment. Typically IOWs address issues involving process variables that, when not adequately monitored or controlled, can impact the likelihood and rates of damage mechanisms, which could result in a loss of containment. IOWs are those preset limits on process variables that need to be established and implemented in order to prevent potential breaches of containment that might occur as a result of not controlling the process sufficiently to avoid unexpected or unplanned deterioration or damage to pressure equipment. Operation within the preset limits should result in predictable and reasonably low rates of degradation. Operation outside the IOW limits could result in unanticipated damage, accelerated damage and potential equipment failure from one or more damage mechanisms. A properly structured, efficient and effective inspection program depends on IOWs being established and implemented to improve inspection planning and to avoid unanticipated impacts on pressure equipment integrity. Inspection plans are typically based on historic damage mechanisms and trends and are not generally designed to look for unanticipated damage resulting from process variability and upsets. Inspection plans generally assume that the next inspection interval (calculated based on prior damage rates from past operating experience) are scheduled on the basis of what is already known and predictable about equipment degradation from previous inspections. Without a set of effective and complete IOWs and feedback loop into the inspection planning process, inspections might need to be scheduled on a more frequent time-based interval just to look for anything that might potentially occur from process variability.

Chevron currently has a work process called RPM that pre-dates API-584, Integrity Operating Windows, but has many of the elements of IOWs. SMEs were tasked with developing critical process variables (CPVs). CPVs are the dynamic system parameters that are essential for controlling a particular outcome in the following areas:

- Equipment reliability (critical reliability variables or CRVs), or
- Environmental compliance (critical environmental variables or CEVs), or
- Process optimization (critical optimization variables or COVs).

Control parameters for the CPVs were established within currently established Honeywell controls to allow for early detection of a process control trending toward an alarm state.

The definition of a CRV is similar to an IOW variable in that a CRV is defined as those variables that, when left in deviation, can lead to degradation of equipment. Some examples of CRVs are:

- Reactor and Furnace tube skin temperatures
- Boiler feed water and cooling water chemistry
- Wash water rates
- Rich and lean DEA loadings
- Piping velocities
- Column and vessel liquid levels

Chevron has reported that the CRVs, CEVs, and COVs have been incorporated into existing process monitoring work processes within Chevron. Roles and responsibilities were reportedly established and the training of key personnel was implemented (not independently verified). In addition, a monitoring tool for all CPVs was established to provide visibility and accountability. The on-line tool that was implemented is Operational Excellence and Reliability Intelligence (OERI). An example of a report from OERI is below (Figure A4.13-REL-1) and describes the monitoring of CRVs in the crude unit overhead reflux drum, V-1100. This report also allows the operators to look at the consequence of deviation (COD) for a particular CRV by clicking on an information icon (see Figure A4.13-REL-2 below).

1.3.7.6 Risk-Based Inspection Assessments

Risk is the combination of the probability of some event occurring during a time period of interest and the consequences, (generally negative) associated with the event. Risk Based Inspection, e.g., API-580, is a risk assessment and management tool that addresses an area not completely addressed in other organizational risk management efforts such as Process Hazards Analyses (PHA) or reliability centered maintenance (RCM). It complements these efforts to provide a more thorough assessment of the risks associated with equipment operations. RBI produces Inspection and Maintenance Plans for equipment that identify the actions that should be implemented to provide reliable and safe operation. The RBI effort can provide input into an organization's annual planning and funds required to maintain equipment operation at acceptable levels of performance and risk.

COD Report from OERI

Condition Information for: 11QF_V1100OVH.P-NH3 - DRE4CUV-1100 NH3 CONC

Consequence of DeviationHigh Limit:

1. Increased salt generation. See Nalco report for current ammonia balance on overhead system to determine ammonium chloride sublimation point or request info from PED. As ammonium chloride sublimes, it leaves salt deposits behind which can corrode the system. If greater than 25 F above C1100 O/H water dew point temperature it's OK.
2. High ammonia in effluent system if ammonia concentration gets too high.

1.3.8 Damage Mechanisms

API-571, “Damage Mechanisms Affecting Equipment in the Refining Industry” lists 66 of the most common damage mechanisms occurring in the refining, petrochemical, pulp and paper and fossil utility industries. API-571 categorizes those damage mechanisms as follows:

- A) Mechanical and metallurgical failure
- B) Uniform or localized loss of thickness
- C) High-temperature corrosion
- D) Environment-assisted cracking

A generally accepted definition of corrosion (a damage mechanism) is the “Naturally occurring phenomenon commonly defined as the deterioration of a substance (usually a metal) or its properties because of a reaction with its environment,” (Van Delinder, 1984). This definition encompasses all materials, both naturally occurring and man-made and includes plastics, ceramics, and metals. This section focuses on the corrosion of metals.

This definition of corrosion begs the question: why do metals corrode? A significant amount of energy is put into a metal when it is extracted from its ores, placing it in a high-energy state. These ores are typically oxides of the metal such as hematite (Fe_2O_3) for steel. A guiding principle of thermodynamics is that a material always seeks the lowest energy state. In other words, most metals are thermodynamically unstable and will tend to seek a lower energy state, which is an oxide or some other compound. The process by which metals convert to the lower-energy oxides is called corrosion.

The corrosion of most common engineering materials at near-ambient temperatures occurs in aqueous (water-containing) environments and is an electrochemical process. The aqueous environment is also referred to as the electrolyte and almost always involves liquid water. The corrosion process involves the removal of electrons (oxidation) of the metal and the consumption of those electrons by a reduction reaction, such as the reduction of dissolved oxygen or water molecules. The oxidation reaction is commonly called the anodic reaction and the reduction reaction is called the cathodic reaction. Both electrochemical reactions are necessary for corrosion to occur. The oxidation reaction causes the actual metal loss but the reduction reaction must be present to consume the electrons liberated by the oxidation reaction, maintaining charge neutrality. Otherwise, a large negative charge would rapidly develop between the metal and the electrolyte and the corrosion process would cease. The oxidation and reduction reactions are sometimes referred to as half-cell reactions (Peabody, 2010).

1.3.9 Eight Forms of Corrosion

The idea of describing the various ways corrosion can damage metals by the appearance of the corrosion has become common place. It is convenient to classify corrosion by the forms in which it manifests itself, the basis for this classification being the appearance of the corroded metal. The eight forms are: (1) uniform, or general attack; (2) galvanic, or two-metal corrosion; (3) crevice corrosion; (4) pitting; (5) intergranular corrosion; (6) selective leaching, or parting; (7) erosion-corrosion; and (8) stress corrosion cracking. This listing is arbitrary but covers practically all corrosion failures and problems. Below, the eight forms of corrosion are discussed in terms of their characteristics, mechanisms, and preventive measures.

1.3.9.1 Uniform Attack

Uniform attack is the most common form of corrosion. It is normally characterized by a chemical or electrochemical reaction which proceeds uniformly over the entire exposed surface or over a large area. The metal becomes thinner and eventually fails. For example, a piece of steel or zinc immersed in dilute sulfuric acid will normally dissolve at a uniform rate over its entire surface. A sheet iron roof will show essentially the same degree of rusting over its entire outside surface.

Uniform attack, or general overall corrosion, represents the greatest destruction of metal on a tonnage basis. This form of corrosion, however, is not of too great concern from the technical standpoint, because the life of equipment can be accurately estimated on the basis of comparatively simple tests. Uniform attack can be prevented or reduced by: (1) proper materials, including coatings; (2) inhibitors; or (3) cathodic protection.

1.3.9.2 Galvanic or Two-Metal Corrosion

A potential difference usually exists between two dissimilar metals when they are immersed in a corrosive or conductive solution. If these metals are placed in contact (or otherwise electrically connected), this potential difference produces electron flow between them. Corrosion of the less corrosion-resistant metal is usually increased and attack of the more resistant material is decreased, as compared with the behavior of these metals when they are not in contact. The less resistant metal becomes anodic and the more resistant metal cathodic. Usually the cathode or cathodic metal corrodes very little or not at all in this type of couple. Because of the electric currents and dissimilar metals involved, this form of corrosion is called galvanic, or two-metal, corrosion. It is electrochemical corrosion, but we shall restrict the term galvanic to dissimilar-metal effects for purposes of clarity.

1.3.9.3 Crevice Corrosion

Intense localized corrosion frequently occurs within crevices and other shielded areas on metal surfaces exposed to corrosives. This type of attack is usually associated with small volumes of stagnant solution caused by holes, gasket surfaces, lap joints, surface deposits, and crevices under bolt and rivet heads. As a result, this form of corrosion is called crevice corrosion.

1.3.9.4 Pitting

Pitting is a form of localized attack that results in localized holes in the metal. The holes may be small or large in diameter, but in most cases they are relatively small. Pits are sometimes isolated or so close together that they look like a rough surface. Generally a pit may be described as a cavity or hole with the surface diameter about the same as or less as the depth.

Pitting is one of the most destructive and most difficult to detect forms of corrosion. It causes equipment to fail because of perforation with only a small percent weight loss of the entire structure. It is often difficult to detect pits because of their small size and because the pits are often covered with corrosion products. In addition, it is difficult to measure quantitatively and compare the extent of pitting because of the varying depths and numbers of pits that may occur under identical conditions. Pitting is also difficult to predict by laboratory tests. Sometimes the pits require a long time, several months or a year to show up in actual service. Pitting is of particular concern because it is a localized and intense form of corrosion, and failures often occur with suddenness.

1.3.9.5 Intergranular Corrosion

Grain boundary impacts are of little or no consequence in most applications or uses of metals. If a metal corrodes, uniform attack normally results as grain boundaries are usually only slightly more reactive than the matrix. However, under certain conditions, grain interfaces are very reactive and intergranular corrosion results. Localized attack at, and adjacent to, grain boundaries, with relatively little metal loss at the grains, is intergranular corrosion. The alloy disintegrates (grains fall out) and/or loses its strength.

Intergranular corrosion can be caused by impurities at the grain boundaries, enrichment of one of the alloying elements, or depletion of one of these elements in the grain-boundary areas. A well-documented form of intergranular corrosion is the depletion of chromium in the grain-boundary regions results in intergranular corrosion (sensitization) of stainless steels.

1.3.9.6 Selective Leaching

Selective leaching is the removal of one element from a solid alloy by corrosion processes. The most common example is the selective removal of zinc in brass

alloys (dezincification). Similar processes occur in other alloy systems in which aluminum; iron, cobalt, chromium, and other elements are removed. Selective leaching is the general term to describe these processes, and its use precludes the creation of terms such as de aluminification, de cobaltification, etc.

1.3.9.7 Erosion-Corrosion

Erosion-corrosion is the acceleration or increase in rate of deterioration or attack on a metal because of relative movement between a corrosive fluid and the metal surface. Generally, this movement is quite rapid, and mechanical wear effects or abrasion are involved. Metal is removed from the surface as dissolved ions, or it forms solid corrosion products which are mechanically swept from the metal surface.

Erosion-corrosion is characterized in appearance by grooves, gullies, waves, rounded holes, and valleys and usually exhibits a directional pattern. In many cases, failures because of erosion corrosion occur in a relatively short time, and they are unexpected largely because evaluation corrosion tests were run under static conditions or because the erosion effects were not considered.

1.3.9.8 Stress Corrosion Cracking (SCC)

Stress-corrosion cracking refers to cracking caused by the simultaneous presence of tensile stress and a specific corrosive medium. During stress-corrosion cracking, the metal or alloy is virtually unattacked over most of its surface, while fine cracks progress through it. This cracking phenomenon has serious consequences since it can occur at stresses within the range of typical design stresses.

Two classic cases of stress-corrosion cracking are “season cracking” of brass, and the “caustic embrittlement” of steel. Both of these terms describe the environmental conditions present which led to stress-corrosion cracking. Season cracking refers to the stress-corrosion cracking failure of brass cartridge cases. During periods of heavy rainfall, especially in the tropics, cracks were observed in the brass cartridge cases at the point where the case was crimped to the bullet. It was later found that the important environmental component in season cracking was ammonia resulting from the decomposition of organic matter.

Many explosions of riveted boilers occurred in early steam-driven locomotives. Examination of these failures showed cracks or brittle failures at the rivet holes. These areas were cold-worked during riveting operations, and analysis of the whitish deposits found in these areas showed caustic, or sodium hydroxide, to be the major component. Hence, brittle fracture in the presence of caustic resulted in the term caustic embrittlement. While stress alone will react in ways well known in mechanical metallurgy (i.e., creep, fatigue, tensile failure) and

corrosion alone will react to produce characteristic dissolution reactions, the simultaneous action of both sometimes produces the disastrous results.

1.3.10 Damage Mechanisms Found in Refineries

All refining corrosion mechanisms can be categorized as a subset of the general eight forms of corrosion summarized above. A listing and description of the most common refining damage mechanisms is found in the API document, *API-571, Damage Mechanisms Affecting Fixed Equipment in the Refining Industry* (API-571, 2011). API-571 has become a Recognized and Generally Accepted Good Engineering Practice (RAGAGEP) regarding damage mechanisms in the refining industry. The starting point for the damage mechanism assessment review was Table 5-4 in API-571. The table is not meant to be an exhaustive list of all damage mechanisms, but to serve as a useful starting point reference. In conducting the Modernization Project damage mechanism review, the API-571 damage mechanism list and other relevant damage mechanisms were considered. A list of the damage mechanisms from API-571 is provided below in Table A4.13-REL-3. For the purposes of the Reliability Analysis, the considered damage mechanisms can be divided into three broad categories: (1) damage mechanisms relevant to a process unit and also impacted by the Modernization Project, (2) damage mechanisms relevant to a process unit, but not impacted by the Modernization Project, and (3) all other damage mechanisms.

An independent analysis of relevant damage mechanisms resulting from anticipated post-Modernization Project operating conditions was conducted, considering the potential feedstock change of increased sulfur, and the conservative possibility of increased nitrogen based on the finding in Appendix 4.3-MET that it is likely that the crude oils processed by the Facility, if the Modernization Project is implemented, would have the potential to contain higher nitrogen levels. The increased sulfur and nitrogen is considered to influence all damage mechanisms identified in Table A4.13-REL-4, except for high-temperature hydrogen attack (HTHA), which is a function of the higher purity hydrogen from the new hydrogen plant, creep/stress rupture, which is a function of temperature, time and stress and oxygen-enhanced ignition and combustion, which results from the new oxygen injection line to the sulfur recovery unit (SRU). The review was conducted considering the extensive body of knowledge regarding the damage mechanisms that result from sulfur and nitrogen compounds in crude oils, depending on the refining units they are routed through, reviewing documents submitted by Chevron regarding their specific crude and product slate processing scheme at the Facility, plus the years of experience of the Reviewer in corrosion processes and identification of damage mechanisms in chemical and refining processes. The independent damage mechanism review did not identify any additional damage mechanisms other than the ones in Table A4.13-REL-4.

TABLE A4.13-REL-3 API-571 LISTING OF DAMAGE MECHANISMS

DM#	Damage Mechanisms	DM#	Damage Mechanisms
1	Sulfidation	33	885°F (475°C) Embrittlement
2	Wet H ₂ S Damage (Blistering/HIC/SOHIC/SSC)	34	Softening (Spheroidization)

1.4 MODERNIZATION PROJECT CHANGES WITH POTENTIAL TO INCREASE RISKS FROM DAMAGE MECHANISMS AT REFINERIES

Chevron owns and operates the Facility, which processes crude oil blends, externally-sourced gas oils, and natural gas into a number of products, including motor gasoline, jet fuel, diesel fuel, and lubricant base oils, as well as fuel oil, liquefied petroleum gas and sulfur.

In 2011, Chevron submitted an application to the City for the Modernization Project that includes a new hydrogen plant and hydrogen purity improvements (sulfur removal improvements). The objectives of the Modernization Project relevant to this Reliability Analysis include:

- Enhance the Facility's flexibility to process crude oil blends and externally sourced gas oils with higher sulfur content; and
- Replace the existing hydrogen production plant with a larger, more modern plant that is more energy-efficient, produces higher purity hydrogen, and has sufficient capacity to meet the Facility's hydrogen needs.

As indicated above, the Modernization Project is designed to improve the Facility's flexibility to process higher sulfur crudes. The Facility currently has the capacity to process crude oil blends with gravity at the lighter end of the intermediate range (intermediate-light), and will remain configured in the same manner to process such crude oil blends after the Modernization Project is implemented. However, the Facility's ability to process more sulfur would allow it to accept more sour crude oil blends at either the higher or lower end of the intermediate-light gravity range. Therefore it is reasonably foreseeable that after

TABLE A4.13-REL-4 FACILITY UNITS AND IDENTIFIED PROJECT-RELATED DAMAGE MECHANISMS IDENTIFIED FOR FURTHER REVIEW

	API-571 Damage Mechanisms	Crude Unit	Hydro-treating	SDA Unit	SRU	Sour Gas (Off plot)	Sour Water Plants (WWT) and Sour Water (off plot)	Recovered Oil
1	Sulfidation	X	X	X				X
2	Wet H ₂ S Damage (Blistering/HIC/SOHIC/SSC)	X	X	X		X	X

13	Sour Water Corrosion (acidic)	X						
65	Oxygen-Enhanced Ignition and Combustion				X			

Note: HIC = hydrogen-induced cracking; SOHIC = stress-oriented hydrogen-induced cracking; SSC = sulfide stress cracking; SDA unit = solvent de-asphalting unit

the Project, the Facility could accept higher quantities of sour crudes that fall in the lower end of the intermediate-light range, resulting in an overall lower average API gravity compared to the average crude gravity run during the baseline period of 2008 to 2010.

Chevron has applied to the City for a conditional use permit (“CUP”) for the Modernization Project. The CUP process for the Modernization Project requires preparation of a revised environmental impact report (“EIR”), which must include analysis of the Modernization Project’s potentially significant impacts on public safety. Specifically, the EIR analyzes whether the Modernization Project could create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment.

Given the objective of the Modernization Project to allow the Facility to process crude oils and externally-sourced gas oils containing higher levels of sulfur than currently being processed, the Modernization Project includes various components that will enable the Facility to process and remove this additional sulfur, and includes an amendment to the Facility’s Title V permit to increase the sulfur removal limit from 600 to 900 long tons per day (lt/d). The 900 lt/d limits equates to an approximate capacity of 3 wt. % sulfur in crude oil blends.

The Modernization Project has physical, operational, and feedstock changes from current existing operations, as described in greater detail in the EIR, *Chapter 3, Project Description*. The Modernization Project changes relevant for this Reliability Analysis are described in further detail in the following sections.

1.4.1 Description of Modernization Project Changes

As discussed above and in *Section 1.2, Scope and Methodology*, the Modernization Project involves several operational and feedstock changes that could have a bearing on the activity of damage mechanisms at the Facility. Each of these operational and feedstock changes is discussed below.

1.4.1.1 Risk Impacts of the Increase in Facility Operational Utilization up to 100% Relative to Baseline Period

Chevron anticipates increasing the refinery operational utilization from 89% up to 93%, and considers the possibility of reaching 100% of its Title V maximum permitted capacity levels. Here, utilization is defined as the average annual operational rate relative to the maximum permitted capacity. For purposes of this Reliability Analysis, utilization is considered to determine the extent to which a planned increase in Facility utilization will materially impact baseline damage mechanism activity.

To respond to the issue of whether an increase in Facility utilization rates have the potential to impact existing equipment/piping damage mechanisms or initiate new ones, one must consider what environmental parameters influence the severity of damage mechanisms. Damage mechanisms resulting from environmental exposure to refinery processes can be broadly categorized into several damage type categories: (a) thinning, (b) cracking, (c) mechanical/metallurgical, and (d) high temperature. An example of a thinning damage mechanism is ammonium bisulfide corrosion. A cracking mechanism would include wet H₂S cracking. A mechanical/metallurgical damage mechanism would include temper embrittlement or brittle fracture. Thinning (corrosion) mechanisms are typically expressed in units of mass loss, or more traditionally, in units of thickness loss per unit of time. The most common unit that thinning is expressed in when studying or reporting on corrosion rates is thousands of an inch per year, or mils per year (mpy). Cracking is more complicated, but cracking can be expressed as time to cracking or whether a material cracks or not in a specific environment (pass-fail).

With that background, Facility utilization doesn't normally materially impact an assessment of the relative risk of thinning mechanisms, as the reported metal loss is typically ratioed over a full year of exposure, regardless of the actual exposure time and it is this "full year" rate which drives risk and decisions on mitigating risk. The risk of damage from cracking is also driven considering "full utilization" exposure time. In fact, common practice is to not consider refinery utilization as a risk parameter nor is a reduced utilization time considered as a risk reduction measure. There are damage mechanisms that can increase in severity based on downtime. Therefore, based on the above rationale, the Project's contemplated increase in Facility utilization would not have a bearing on damage mechanism activity and does not warrant further analysis in this Reliability Analysis as full time exposures were conservatively considered.

1.4.1.2 Impact of Project Operational and Feedstock Changes on Risk

This section discusses the methodology and rationale used to define what operating units (processing equipment and components) at the Facility would be potentially impacted by the Modernization Project, based on damage mechanisms affected by the operational and feedstock changes of the Project. It also describes which operating units (processing equipment and components) were determined not to be affected by the Modernization Project.

Chevron's Modernization Project goal of increasing its flexibility to refine higher sulfur crude and gas oils and to refine more crude oil at the lower end of the intermediate gravity range will result in the acceptance of higher sulfur crude oil blends and gas oils and has the potential to result in the processing of crude oil blends in a lower gravity range than was processed during the baseline period.

The Project's operational and feedstock changes could result in the following changes in parameters relevant to the reliability and damage mechanism review and which were further evaluated:

- Increased wt. % sulfur in feedstocks (crude and gas oils);
- Increased hydrogen (H_2) purity (partial pressure) produced from a new hydrogen plant;
- Increased H_2S partial pressures in refinery processing units where the sulfur in the crude is either intentionally, or as a by-product of other reactions, converted to other sulfur containing compounds;
- Increase in nitrogen content based on a moderate to strong statistical relationship found between API gravity in the intermediate-light gravity range (between 28 and 40 API) and nitrogen content and a weak correlation between sulfur and nitrogen content as described in Appendix 4.3-MET; and
- Increased ammonium bisulfide content of many process streams due to increased nitrogen in the feedstocks.

The primary driving force for additional damage mechanisms and/or the increased severity of existing damage mechanisms is the planned increase in total sulfur content of purchased crude and supplemental gas oil feed to the Facility associated with the Project. The current baseline sulfur content of blended crude feed is approximately 1.58 wt.% on an annual-average basis. Two crude blend cases considered in this reliability and damage mechanism analysis were a 2.38 wt.% sulfur (P-50 case) and a sulfur content of 3.28 wt.% sulfur (the P-90 case). The P-50 case is the most likely future high sulfur case, considering other Facility operating constraints, with 2.38 wt.% sulfur content and 32.3 API gravity, approximating the URM project crude blend of 2.5 wt. % sulfur and 31.6 API gravity (Appendix 4.3-URM). Chevron identified a "P-90" analytical case of 3.28 wt. % sulfur and API gravity of 28.4, which approximates the "heaviest crude blend" and the "most sour crude blend" scenarios from the URM. The P-90 case was selected to represent an extremely conservative scenario because the 3.28 wt.% level is much higher than the reasonably foreseeable and planned annual average sulfur content post-Modernization Project, and would also result in much lower overall Facility utilization per the sulfur recovery unit constraint, as noted in the Unit Rate Model included as Appendix 4.3-URM.

Other changes include the new hydrogen plant, which could potentially add additional damage mechanisms and/or an increased severity of existing damage mechanisms by increasing the purity of hydrogen feed to several refinery units that use hydrogen to process and reduce sulfur in sulfur containing hydrocarbons (e.g., HP units). In addition, various physical changes/additions to accommodate the increased H_2S and ammonium bisulfide content in sour gas

streams occurring in sulfur conversion (hydroprocessing) units could potentially add additional damage mechanisms and/or the increased severity of existing damage mechanisms. The potential impacts of the Modernization Project's physical changes are discussed in *Section 4.13, Public Safety* of the EIR.

The increased sulfur content in purchased crude and gas oils is anticipated to be the primary reason for an increased severity of damage mechanisms associated with the Modernization Project. The identified increased damage mechanisms resulting from the higher sulfur crude include high-temperature sulfidation, high-temperature H_2 - H_2S corrosion, wet H_2S damage (SSC/hydrogen-induced cracking [HIC] / SOHIC), acidic sour water corrosion, ammonium bisulfide corrosion (sour water corrosion) and ammonium chloride corrosion. The extent of the damage caused by sulfur and the units and equipment it impacts is based on the amount of sulfur, the processing conditions the sulfur is exposed to and the materials of construction of the equipment exposed to the sulfur compounds.

The Reliability Analysis methodology approach was based on a combination of: (1) the Reviewer's personal experience; (2) interviews/information provided by a panel of Facility and Technical Department SMEs from several technical disciplines, including Process Engineering, Technical Department Materials and Equipment Engineering, and refinery Materials Engineering personnel, with support from other departments as needed; (3) a review of Chevron provided and requested documents; and, (4) a review of available published papers and industry standards and recommended practices.

1.5 UNITS IMPACTED BY THE MODERNIZATION PROJECT BASED ON OPERATIONAL AND FEEDSTOCK CHANGES

The general process to determine which Facility units would, and would not, be impacted by the Modernization Project included the following steps:

1. Conduct a sulfur mass balance to determine the estimated sulfur in the various crude unit product streams and the related sulfur-levels of the feed to downstream units.
2. Conduct a nitrogen mass balance to determine the routing and amount of nitrogen going to the different processing units.
3. Review which units would be impacted by hydrogen introduced to the unit from the new hydrogen plant.
4. Review all Project physical changes.
5. Using API-571, *Damage Mechanisms Affecting Fixed Equipment in the Refining Industry*, 2011, as a reference, plus the Reviewer's experience and

the wealth of industry and technical associated published literature regarding damage mechanisms in refineries, determine the reliability impacts that could arise from the reasonably foreseeable changes to current process conditions that would result from construction and operation of the Modernization Project.

6. Determine any reliability impacts based on other available sources, including standards, guidelines or lessons learned.

To determine which processing units would be affected by an increase in sulfur content of crude and/or imported gas oil, the sulfur containing streams were traced from where the crude first entered the refinery at the crude unit through downstream processing units in the refinery to a point where: (1) the sulfur became extinct (i.e., removed); (2) the sulfur levels returned to baseline levels; or (3) sulfur in the crude, where converted to other, lighter sulfur compounds through contact with heat, pressure or catalysts, was at the original baseline level. A similar approach was used to evaluate changes in nitrogen, hydrogen purity and H_2S . Figure A4.13-REL-3 provides a summary of the impacted and non-impacted units resulting from the review.

Table A4.13-REL-4 details the processing units and their associated Modernization Project relevant damage mechanisms that were considered to apply to post-Modernization Project operating conditions based on the review steps described above. The damage mechanisms themselves are discussed subsequently.

1.6 UNITS NOT IMPACTED BY THE MODERNIZATION PROJECT BASED ON OPERATIONAL AND FEEDSTOCK CHANGES

Several units were determined not to be affected by operational and feedstock changes of the Modernization Project, as listed below. A review of post-modernization physical changes was not considered to be in the scope of this review, with the exception of the new amine equipment. Based on the intended service of the new amine equipment it was not considered to be impacted by post-Modernization Project operational or feedstock changes; therefore, was not included in Table A4.13-REL-4 as an impacted unit. However, it was decided to discuss the unit in the impacted unit section to provide an explanation for why the risk for damage mechanisms normally associated with amine unit would not increase with the Project.

The Richmond Refinery

02.20.2014 file path: U:\Chevron Renewal\ENVIRON\Files\Report\Figures\DEIR Figures\REL

Source: Chevron (T85)

Figure A4.13-REL-3
Chevron Refinery Modernization Project EIR
Facility Streams Impacted by Modernization Project

1.6.1 Fluid Catalytic Cracker Unit

Feeds are TKC desulfurized gas oil and purchased gas oil. Feed does not change to this unit with the Modernization Project and hydrogen is not used at this unit. The fluid catalytic cracker unit does not remove sulfur, and the fluid catalytic cracker unit makes gasoline as its primary product. California limits the sulfur content of gasoline (and diesel), so the sulfur level of gas oil feedstocks to the fluid catalytic cracker unit could not change enough to exceed the sulfur content requirements in the sulfur levels set by California.

1.6.2 Isomerization/Penhex

Feed does not change to this unit with the Modernization Project. The feed to this unit is desulfurized and denitrified at the Naphtha Hydrotreater (NHT) to an existing specification sampled weekly, as specified in Electronic Operating Manual for the NHT, since sulfur and nitrogen are poisons to the Penhex catalyst. The existing feed sulfur level specification will not change with the Project (Chevron, [n.d.1]). If the current specification or actual operational data changes in the future from the existing conditions, then Chevron should evaluate the change using the reliability and damage mechanism review approach outlined in this Appendix. Chevron should then submit a report on the change and the findings of the reliability review to the City.

Make-up hydrogen used in this unit comes from the Rheniformer units and not from the new hydrogen plant so purity of hydrogen will not change to this unit as a result of the Modernization Project.

1.6.3 Alkylation

Feed does not change to this unit with the Project nor is hydrogen used at this unit. Feed is from the fluid catalytic cracker unit, which does not change from existing conditions with the Modernization Project, as described above.

1.6.4 No. 4 and 5 Rheniformers

Feed does not change to these units with the Modernization Project. Pre-treated gasoline and naphtha from the Isomax and NHT are the feeds to this unit and existing specifications for sulfur to this unit, reviewed by the Reviewer as a part of the Reliability Analysis, will not change as a result of the Modernization Project. If the current specification or actual operational data changes in the future from the existing conditions, then Chevron should evaluate the change using the reliability and damage mechanism review approach outlined in this Appendix. Chevron should then submit a report on the change and the findings of the reliability review to the City.

Hydrogen is produced in these units and used in other units at the refinery. No hydrogen from the new hydrogen plant will be used here.

1.6.5 Yard Deisobutanizer (YDIB)

This unit recovers isobutane at units (yard LPG, Butamer, RLOP and Isomax gas recovery units) downstream of the sulfur removal processes at the Facility; therefore its input and output streams will not change from existing conditions as a result of the Modernization Project.

1.6.6 Naphtha/Reformatte Splitter

Feed does not change to this unit with the Project. The naphtha splitter feed is from the NHT and has an existing specification for sulfur and nitrogen which will not change with the Modernization Project. If the current specification or actual operational data changes in the future from the existing conditions, then Chevron should evaluate the change using the reliability and damage mechanism review approach outlined in this Appendix. Chevron should then submit a report on the change and the findings of the reliability review to the City.

The reformatte splitter feed is from the Rheniformers which will not change from existing conditions.

1.6.7 Butamer

The feed to this unit is from the YDIB and Alkylation units, both of which do not change with the Modernization Project.

1.6.8 LNF/HNF

Feed to the Light and Heavy Neutral Finishers will not change post-Modernization Project since the upstream units, the LNC and HNC, desulfurize and denitrify to the same level as current specifications.

1.6.9 ISOMAX Reactors

The feed to the ISO Reactors will not change post-Modernization Project since the feed is pretreated in the upstream TKN unit, which desulfurizes and denitrifies to the same level as current specification.

1.6.10 Propoly Plant/Selective Hydrogenation Unit (SHU)

The feed to the Propoly plant and the SHU will not change post-Modernization Project since both units process LPG from the fluid catalytic cracker. Since fluid catalytic cracker feed quality does not change with the Modernization Project, the feed to the Propoly and SHU does not change.

1.6.11 Gasoline Hydrotreater (GHT)

The feed to the GHT will not change post-Modernization Project since the GHT desulfurizes a fluid catalytic cracker gasoline stream and the fluid catalytic cracker feed will not change.

1.7 DAMAGE MECHANISMS ACTIVE IN THE FACILITY AND IMPACTED BY THE MODERNIZATION PROJECT'S OPERATIONAL AND FEEDSTOCK CHANGES

The following guidelines were used to determine if any of the damage mechanisms applied to a particular plant or process system:

1. Determine which operating plants and systems were going to change as a result of the Modernization Project, based on:
 1. Operational changes
 2. Sulfur wt. % change
 3. Increase in hydrogen purity
 4. A sensitivity analysis regarding a potentially higher nitrogen crude case
 5. Introduction of, or increase in corrosive constituents resulting from a change in sulfur, nitrogen or hydrogen purity
 6. Process monitoring tools such as process monitoring and optimization (PMO) and INDX
2. Determine the particular sections of the operating plants or systems that might be affected. Tools used to help with this analysis included:
 - Piping Isometrics
 - Piping and Instrumentation Diagrams
 - Process Flow Diagrams
 - Metallurgy of piping and equipment
 - Chevron Best Practice Documents
 - Industry published papers and guidelines, recommended practices, etc.
 - Process Descriptions

3. Use industry and Chevron standards to assist in evaluating whether the damage mechanism may have an effect on the particular unit, based on a review of critical factors. The below is a representative sampling of documents reviewed:

- High-temperature sulfidation corrosion– API-939-C, *Guidelines for Avoiding Sulfidation Failures in Refineries* (API-939-C, 2009), and Chevron’s guidelines on inspection on deadlegs (Chevron [n.d.5]) and sulfidation service (Chevron, 2009).
- High-temperature H_2 - H_2S corrosion – Couper-Gorman curves.
- Ammonium Bisulfide – Chevron Hydroprocessing Best Practice, HP-002 (Chevron [n.d.3]).
- API-932-B, *Design, Materials, Fabrication, Operation, and Inspection Guidelines for Corrosion Control in Hydroprocessing Reactor Effluent Air Cooler (REAC) Systems* (API-932-B, 2012).
- API-571, *Damage Mechanisms Affecting Fixed Equipment in the Refining Industry* (API-571, 2011).
- API-581, *Risk Based Inspection Technology* (API-581, 2008).

Each of the Modernization Project-impacted units identified in Table A4.13-REL-4 underwent more detailed analysis for the damage mechanisms identified as being impacted by post-Modernization Project conditions for that unit.

1.7.1 High-Temperature Sulfidation

Crude and gas oils are processed into final products through a series of separation steps that include heating of the oils for distillation (i.e., separation of liquids based on boiling points). When heated to high temperatures (i.e., above 500°F), sulfur-containing crude oil blends and gas oils (or fractions of these oils) can thin the metal at the inside surface of a pipe or piece of equipment through a corrosion process called high temperature sulfidation (HTS). HTS results from a chemical reaction of the reactive sulfur in the crude or gas oil with the metal surface of the piping or equipment to form an iron sulfide scale. Over time, this results in reduced metal thickness and ultimately can result in failure (i.e., a leak) of pressure containing equipment. Thinning of metal from sulfidation corrosion almost always occurs as uniform metal loss; that is, the wall thickness of the pipe or equipment decreases evenly along the length of the wall over time. The metal loss due to sulfidation is uniform because it results from the diffusion (i.e., movement) of sulfur species from the process environment (i.e., the crude oil) through the sulfide scale that forms on the inside surface of the pipe or equipment to the metal surface where it reacts with the metal. This action of the

sulfur occurs over the entire surface covered with the sulfide scale; thus resulting in a characteristic uniform loss. As a result of the uniform metal loss, sulfidation corrosion failure of a pipe or equipment typically causes a large rupture.

1.7.1.1 Critical Factors

There are several factors that may affect the rate of high-temperature sulfidation:

1.7.1.1.1 Temperature

Temperature is the most important parameter that influences sulfidation corrosion rates. For example, a 10% change in temperature is more significant than a 10% change in the other factors, such as sulfur content. 500°F is considered to be the threshold temperature where sulfidation of carbon steel becomes a significant. Below 450°F (230°C), the corrosion rate is essentially nil. The corrosion rate increases with temperature from approximately 450°F (230°C) to about 800°F.

1.7.1.1.2 Amount of Sulfur

All other conditions (i.e., temperature, hydrogen level, sulfur species and steel type) being equal, increasing the sulfur level can increase the sulfidation corrosion rate.

1.7.1.1.3 Type(s) of Sulfur Species Present:

Different sulfur species in a crude oil have different levels of reactivity and can influence the rate of high-temperature sulfidation corrosion differently. Most crude oils contain a range of sulfur species including H_2S , mercaptans, elemental sulfur, polysulfides, thiophenes, aliphatic sulfides and aliphatic disulfides and each has a different reactivity or effect on corrosion rate. Sulfur compounds tend to concentrate in heavier liquid fractions, but given the same sulfur content and temperature, light gaseous hydrocarbons appear to be more aggressive.

1.7.1.1.4 Presence of Hydrogen

A fundamental difference of H_2 - H_2S corrosion vs H_2 -free corrosion is that low-alloy steels up through 12Cr are less effective in avoiding H_2 - H_2S corrosion than in H_2 -free streams, depending on the severity of the service. The 18Cr-8Ni stainless steels are most commonly used to obtain acceptable corrosion resistance.

1.7.1.1.5 Alloy

The sulfidation resistance generally increases with the amount of chromium in the alloy. For example, in sulfidation service the McConomy curves show increasing resistance with increasing amounts of chromium, i.e., 9Cr will corrode less than 5Cr, which corrodes less than carbon steel. The exact reason for the beneficial effect of Cr is not clear, but it is believed to be related to the stability and protective nature of the iron-chromium-sulfide scales formed.

1.7.1.1.6 Si Content

Carbon steels with low-silicon (< 0.10 %) content can corrode at an accelerated rate when exposed to H₂-free sulfidation corrosion conditions.

1.7.1.1.7 Other Parameters

Coking can reduce the corrosion rate in non-fired equipment such as pressure vessels and piping due to the presence of a protective coke layer that prevents contact with the metal substrate with the corrosive sulfur compounds.

1.7.1.2 Where Does Sulfidation Corrosion Occur?

Sulfidation can occur in refinery process units where equipment and piping are exposed to temperatures above 500°F with sulfur compounds present. Below are examples of refining units where sulfidation is known to occur, depending on specific processing conditions.

Crude unit – Sulfidation in a crude unit can occur in the hotter portions of the unit (>~500°F) in streams containing sulfur compounds. Sulfidation corrosion can first be an issue in the crude preheat train, including the crude charge furnace, where the crude is heated before going to the atmospheric tower. The atmospheric tower distills the crude into boiling point fractions, typically into broad categories of overhead products, side draw products and bottoms resid (vacuum residue). Sulfidation corrosion can occur in the atmospheric tower from the mid-section down to the bottom section where temperatures are greater than the abovementioned 500°F. Sulfidation corrosion is typically an issue starting in the 3rd side cut through the bottom of the atmospheric tower where temperatures are greater than 500°F. Sulfidation corrosion is also a concern in the hotter sections of the vacuum system, including the charge heater, vacuum tower and piping.

Hydroprocessing Unit – Sulfidation corrosion can occur wherever sulfur compounds are present in a hydrocarbon stream and the temperature exceeds approximately 500°F. H₂S corrosion can also occur in the absence of hydrocarbons. In HP units there are two forms of sulfidation corrosion occurring, with and without, hydrogen. Areas of sulfidation corrosion in HP units without hydrogen typically occur in the feed preheat train up to the point where hydrogen is injected into the process. After the hydrogen injection, the H₂-H₂S form of sulfidation predominates until the hydrogen is removed in the high- and low-pressure separation drums.

A fundamental difference of H₂-H₂S corrosion vs H₂-free corrosion, which is common to HP units, is that low-alloy steels up through 12Cr are less effective in avoiding H₂-H₂S corrosion than in H₂-free streams. The 18Cr-8Ni stainless steels are most commonly used to obtain acceptable corrosion resistance when there are significant amounts of hydrogen.

Sulfur Recovery Unit - Sulfidation in a sulfur recovery unit typically is caused by H_2S . Since hydrogen is not present in significant quantities in a sulfur recovery unit, the McConey curves are used to predict corrosion rates.

Fluid Catalytic Cracker Units – Sulfidation in fluid catalytic cracker units normally occurs in the reactor effluent line, the hotter portions of the main fractionator and associated fractionator sidecut and bottoms piping. Although H_2S corrosion rates usually increase with temperature, fluid catalytic cracker experience deviates from this. H_2S corrosion in fluid catalytic cracker reactors occurs at far lower rates than one would expect. For example, some fluid catalytic cracker units use carbon steel cyclones in reactors which last for up to 10 years at operating temperatures of 900-960°F.

1.7.2 High-Temperature H_2 - H_2S Corrosion

Corrosion by H_2S in the presence of hydrogen occurs via the same mechanism as corrosion by sulfur-containing oils in the absence of hydrogen. However, presence of hydrogen tends to increase the rate of sulfidic corrosion by decreasing the protectiveness of the sulfide scale and by enhancing the liberation of H_2S from other sulfur species present. The “Couper-Gorman curves” provide industry-accepted estimates of the corrosion rates in H_2 - H_2S environments as a function of temperature and H_2S concentration. Two sets of curves are used for carbon steel and the Cr-Mo steels - one set for naphtha desulfurizers (typical for streams containing mostly vaporized hydrocarbon) and one set for gas oil desulfurizers (typical for streams containing a significant amount of liquid hydrocarbon). For 12Cr steel and 18-8 stainless steel, only one set of curves are provided to cover both environments.

1.7.2.1 Critical Factors

The major factors affecting high temperature sulfidation are the temperature, the presence of hydrogen, the concentration of H_2S and the alloy composition. When hydrogen is present in significant quantities, corrosion rates are higher than those associated with high temperature sulfidation in the absence of hydrogen. Sulfidation rates increase with increasing H_2S content and especially with increasing temperature. Susceptibility to sulfidation is determined by the chemical composition of the alloy. Increasing chromium content of the alloy improves resistance (API-571, Figure 5-4).

Carbon steel is resistant to corrosion by H_2 - H_2S at temperatures up to about 480°F. 5 Cr, 9 Cr and 12 Cr steels provide better resistance than carbon steel and the austenitic stainless steels (typically 18 Cr – 8 Ni) offer by far the greatest resistance because of their nickel content. The Couper-Gorman curves are used to select materials for equipment and piping that handle H_2 - H_2S environments. The Couper-Gorman curves are also used to obtain a conservative estimate of corrosion by gas phases containing H_2S in the absence of hydrogen.

1.7.2.2 Affected equipment and units

H₂-H₂S corrosion occurs in piping and equipment in units where high temperature H₂-H₂S streams are found, including all HP units such desulfurizers, hydrotreaters and hydrocracking units.

1.7.3 Wet Hydrogen Sulfide Damage (SSC/HIC/SOHIC)

1.7.3.1 Description of Mechanism

Wet H₂S damage is manifested as several different types of metal deterioration

Wet H₂S damage can occur in four ways:

1. Hydrogen Blistering. During the corrosion process, hydrogen atoms from corrosion at the corroding surface diffuse into the steel and gather at an inclusion, lamination, or other discontinuity. This hydrogen accumulation can cause the metal surface to bulge on the ID, the OD or within the wall thickness of a pipe or pressure vessel. When hydrogen molecules formed from the combination of the atoms become too large to diffuse out a local deformation from the pressure build-up forms a blister.
2. Hydrogen-Induced Cracking. Cracks can develop between hydrogen blisters, described above, located at different depths from the surface of the steel. The interconnecting cracks link adjacent or neighboring blisters, often in a stair or step pattern, which is sometimes referred to as “stepwise cracking.”
3. Stress-Oriented Hydrogen-Induced Cracking (SOHIC). When arrays of cracks from HIC form in a stacked pattern on top of one another, a crack perpendicular to the surface through the thickness of the metal can form from high levels of residual or applied stress. These cracks, which are potentially more damaging than HIC, typically form in the base metal adjacent to the weld heat affected zones from HIC, sulfide stress cracks, or other defects.
4. Sulfide Stress Cracking (SSC). The combination of tensile stress and corrosion in the presence of water and H₂S can cause cracking of metal. SSC occurs when hydrogen atoms produced from sulfide corrosion absorb into the metal. SSC can occur in highly localized zones of high hardness in the weld metal and heat affected zones.

1.7.3.2 Critical Factors

The four forms of wet H₂S damage are affected and differentiated by several critical factors, including environmental conditions (pH, H₂S level, contaminants, temperature), material properties (hardness, microstructure, strength) and tensile stress level (applied or residual). These damage mechanisms can occur throughout the refinery wherever a wet H₂S environment is present.

1.7.3.3 Where It Can Occur

Wet H_2S cracking occurs in carbon steel plates (e.g., the walls of pressure vessels) and larger-diameter carbon steel pipes.

1.7.4 Creep—Stress Rupture

1.7.4.1 Description of Mechanism

Creep occurs when metal components slowly and continuously deform under load below the yield stress at high temperatures. Damage can form from the deformation and could eventually lead to rupture. Creep affects all metals and alloys.

1.7.4.2 Critical Factors

The critical factors that determine the creep deformation rate are material, load (stress), and temperature. The rate at which damage occurs (strain rate) is determined by both load and temperature. A temperature threshold exists for each metal; when the metal temperature is above the threshold, creep damage can occur, depending on the stress.

1.7.4.3 Where It Can Occur

Examples of equipment that operate in or near the creep range temperatures in a refinery include: heater tubes in fire heaters, tube supports, hangers, other furnace internals, hot-wall catalytic reforming reactors and furnace tubes, hydrogen reforming furnace tubes, hot wall fluid catalytic cracker reactors, and fluid catalytic cracker main fractionator and regenerator internals. Additionally, creep can occur in vessels and piping near major structural discontinuities including pipe tee joints, nozzles, or welds at flaws. These areas typically have both high metal temperatures and a concentration of stress.

1.7.5 Ammonia Bisulfide Corrosion (Alkaline Sour Water)

1.7.5.1 Description of Mechanism

Hydroprocessing reactor effluent streams and units handling alkaline sour water are susceptible to aggressive localized corrosion. Below about 250°F, NH_4HS can precipitate out of the gas phase in the reactor effluent stream and can cause fouling and plugging. NH_4HS salt deposits lead to underdeposit corrosion and fouling. If the salts become hydrated, they can be very corrosive. Additionally, wash water containing oxygen and iron injected into the hydroprocessing reactor effluent can also increase corrosion and fouling. This corrosion has led to several major failures in hydroprocessing reactor effluent systems. Carbon steel is especially vulnerable to this type of corrosion. 300 Series stainless steels (SS), duplex SS, aluminum alloys, and nickel based alloys have more resistance to this corrosion, depending on the concentration of ammonium bisulfide (NH_4HS) and

the velocity. NH_4HS is formed in the hydroprocessing reactors, fluid catalytic cracker reactors, and coker furnaces from the conversion of Nitrogen into ammonia reacting with H_2S formed from sulfur conversion.

1.7.5.2 Critical Factors

The critical factors that influence alkaline sour water corrosion include NH_4HS concentration, H_2S partial pressure, velocity and/or localized turbulence, pH, temperature, alloy composition and flow distribution. Corrosion increases with increasing velocity and NH_4HS concentration (above about 2 wt.%).

1.7.5.3 Where It Can Occur

HP units, fluid catalytic cracker units, sour water strippers (SWS), amine units, and delayed cokers can be affected by this type of corrosion. Heat exchangers can become plugged and lose their functionality from fouling, and brass tubes and other copper alloys are vulnerable to rapid corrosion from NH_4HS .

1.7.6 Ammonium Chloride Corrosion

1.7.6.1 Description of Mechanism

Ammonium chloride corrosion can occur under ammonium chloride or amine salt deposits often in the absence of a free water phase. This type of corrosion can be general or localized and frequently occurs as pitting. Corrosion rates can be very high. According to the API-571, “all commonly used materials are susceptible.”

1.7.6.2 Critical Factors

The critical factors affecting the ammonium chloride corrosion and corrosion rate are the concentration of NH_3 and HCl , temperature, and water availability. Ammonium chloride salts can precipitate from the cooling of high-temperature streams. These can corrode piping and equipment at temperatures beginning at about 300°F. Ammonium chloride salts are able to absorb water and become corrosive to equipment and piping in the absence of a free liquid water phase.

1.7.6.3 Where It Can Occur

In general, crude tower overheads (tower top, overhead piping and exchangers, and top pump around streams) can become corroded by ammonia and/or amine/ammonium chloride salts. Reactor effluent streams in the hydroprocessing unit are vulnerable to ammonium chloride salt fouling and corrosion. Within the catalytic reforming process, reactor effluent streams are subject to ammonium chloride salting and corrosion. Additionally, the fluid catalytic cracker unit overheads and top pump arounds are also susceptible to these processes.

1.7.7 High-Temperature Hydrogen Attack

1.7.7.1 Description of Mechanism

High Temperature Hydrogen Attack (HTHA) damage is caused by a reaction between hydrogen gas that diffuses through steel and carbide particles in the steel to form methane gas (CH_4). The formation of methane gas in the steel causes internal voids, fissures and cracks that weaken the steel. Failure due to HTHA most frequently occurs as a comparatively small leak resulting from the internal fissures and cracks that progress through the entire thickness of a pressure containing component, such as a vessel or piping.

In the same way that the McConomy curves are used to assist in selection of appropriate materials when high temperature sulfidation (HTS) is a concern, the Nelson Curves in API-941, *Steels for Hydrogen Service at Elevated Temperatures and Pressures in Petroleum Refineries and Petrochemical Plants* (API 941, 2008), is used to help in selection of materials when HTHA is a concern. The Nelson Curves provide limits for steels as a function of temperature and hydrogen partial pressure.

1.7.7.2 Critical Factors

For a specific material, HTHA is dependent on temperature, hydrogen partial pressure, time and stress. The service exposure time is cumulative. HTHA is preceded by a period of time when no noticeable change in properties is detectable by normal inspection techniques. All carbon and low alloy steels are susceptible to HTHA embrittlement, depending on the specific operating conditions of hydrogen partial pressure and temperature, including in order of increasing resistance carbon steel, C-0.5Mo, Mn-0.5Mo, 1Cr-0.5Mo, 1.25Cr-0.5Mo, 2.25Cr-1Mo, 2.25Cr-1Mo-V, 3Cr-1Mo, 5Cr-0.5Mo, 9Cr-1Mo and similar steels with variations in chemistry. The austenitic stainless steels, 304SS/316SS are considered immune to HTHA under normal refining processing conditions.

Two types of deterioration of steel occur in hydrogen service at elevated temperatures: (1) surface decarburization and (2) internal decarburization/fissuring. Surface decarburization is the predominant mode of deterioration at low hydrogen partial pressures (below 100 psia) and high temperatures (above 900°F). Internal decarburization/fissuring is the predominant mode of deterioration at lower temperatures (between 430°F and 900°F) and at higher hydrogen partial pressures (above 100 psia).

1.7.7.3 Where it can occur

HTHA can occur in the following process units:

- Hydrotreating Units

- Hydrocracking Units
- Catalytic Reforming Units
- Hydrogen Plants Isomerization Units

The Chevron Modernization Project will install a new hydrogen manufacturing facility which will increase hydrogen purity and hydrogen partial pressure.

1.7.8 Acidic Sour Water Corrosion

1.7.8.1 Description of Mechanism

Another form of metal corrosion risk occurs when H_2S gas interacts with water and creates acidic sour water with a pH of 4.5 to 7.0. The sour water can contain highly soluble levels of ammonia, chlorides, cyanides that may affect the pH. Carbon steel is affected by this type of corrosion; stainless steels, copper alloys, and nickel base alloys are generally resistant.

1.7.8.2 Critical Factors

The primary factors that determine acidic sour water corrosion are H_2S content, pH, temperature, velocity, and oxygen concentration. The pH of a solution decreases as the concentration of H_2S increases. When the pH of a stream falls below 4.5, corrosion can become severe. HCl and CO_2 can also increase the acidity of the stream. In addition, the presence of air or oxidants increase corrosion rates and tend to produce pitting or underdeposit attack.

1.7.8.3 Where It Can Occur

Acidic sour water corrosion can be a concern in overhead systems of crude units, fluid catalytic cracker and coker gas fractionation plants with high H_2S levels and low NH_3 levels.

1.7.9 Oxygen-Enhanced Ignition and Combustion

1.7.9.1 Description of Mechanism

Even at low pressures, many metals that are non-flammable in air are flammable in oxygen and enriched air (>25%) services. If not properly designed, operated, or maintained, metallic and non-metallic components that spontaneously ignite or combust can turn into fires or explosions in the right oxygen-enriched gaseous environments. Once they ignite, metals and non-metals continue to burn aggressively with higher oxygen purity, temperature, and pressure. Materials affected, with varying degrees of resistance, include carbon steels and low alloy steels, austenitic stainless steels (300 Series), titanium alloys, aluminum, plastics, rubbers, and hydrocarbon lubricants. Copper alloys (with >55% copper) and nickel alloys (with >50% nickel) are very fire resistant.

1.7.9.2 Critical Factors

Several factors contribute to the combustion and ignition of materials, including the system pressure, oxygen concentration of the stream, line velocity, component thickness, design and piping configuration, cleanliness and temperature. As temperature increases, ignition and sustained combustion require a lower amount of added energy (ignition temperature). The entrainment of particles in flowing oxygen can strike impingement areas, such as sharp elbows, tees, and valves, and pose an increased risk for ignition during high velocity oxygen flow conditions. Additionally, contamination of a process with metallic fines or oils and greases during construction or maintenance activities can lead to fires during unit startup.

1.7.9.3 Where It Can Occur

All units that use oxygen or enriched air for combustion or processing are susceptible to this damage mechanism. In general, oxygen is sometimes used in the sulfur recovery unit, fluid catalytic cracker, gasification, and partial oxidation (POX) units. Especially vulnerable to this type of damage are oxygen piping systems, particularly valves, regulators, and other impingement areas.

1.8 DAMAGE MECHANISMS POTENTIALLY ACTIVE IN THE FACILITY IMPACTED UNITS BUT DETERMINED TO BE NOT AFFECTED BY THE MODERNIZATION PROJECT

Below are listed damage mechanisms that could be active in the Impacted Units of the Facility but were not considered to be affected by the Modernization Project. There are other damage mechanisms listed in API-571 Table 5-4 that aren't covered in this Appendix; however, they would be mechanisms that are associated with non-impacted units and therefore are not evaluated further as a part of this Reliability Analysis.

1.8.1 Polythionic Acid Cracking

Polythionic Acid Cracking is a form of stress corrosion cracking normally occurring during shutdowns, startups or during operation when air and moisture are present. Cracking is due to sulfur acids forming from sulfide scale, air and moisture acting on sensitized austenitic stainless steels.

There is no austenitic stainless steel fixed equipment or piping in the crude unit with pressure boundary containment so this damage mechanism does not apply in the existing setting nor post-Modernization Project.

1.8.2 Localized Flow Accelerated Corrosion (FAC)

Chevron has listed FAC as a potential damage mechanism for the crude unit overhead system in their Crude Unit Atmospheric Overhead Corrosion Control

Best Practice document (May 2005), but did not include this mechanism in their API-571 damage mechanism spreadsheet matrix for the crude unit. They have defined FAC as “a long term corrosion mechanism that causes gradually thinning at points of high velocity liquid impingement.” Based on discussions with Chevron corrosion and materials personnel, FAC was intended to describe accelerated thinning due to high liquid velocities and/or turbulence at unpredictable locations. The term FAC is not intended to refer to the specific corrosion mechanism sometimes associated with steam/boiler water systems, particularly documented in the power industry.

1.8.3 Naphthenic Acid Corrosion

Naphthenic acid corrosion (NAC) is a form of high-temperature corrosion that occurs primarily in crude and vacuum units, and downstream units that process certain fractions or cuts that contain naphthenic acids. NAC is a function of the naphthenic acid content (neutralization or TAN number), temperature, sulfur content, velocity and alloy composition.

NAC is not expected to be a viable damage mechanism in the No. 4 crude unit, based on the low naphthenic acid crudes that are expected to be processed based on the post-Modernization Project (Chevron has an existing flag on accepting crude blends with TAN numbers greater than 0.3 mg/kg which will continue post-Modernization Project to avoid NAC corrosion). Therefore, post-Modernization Project conditions are not expected to result in an increase in current naphthenic acid content of crudes.

1.8.4 HCl Corrosion

HCL corrosion is considered to be an active damage mechanism in the crude unit overhead system; however, since its formation primarily depends on the amount of hydrolysable chlorides going overhead in the atmospheric tower from chlorides in the crude and a correlation between post-Modernization Project crude blends and chlorides was not established (Appendix 4.3-MET), HCL corrosion is not considered a post-Modernization Project damage mechanism.

1.8.5 Oxidation

Oxidation is a damage mechanism whereby oxygen reacts with carbon steel and other alloys at high temperature converting the metal to oxide scale. It is most often present as oxygen in the surrounding air (approximately 20%) used for combustion in fired heaters and boilers.

Oxidation could conceivably be a viable damage mechanism in the atmospheric tower furnace; however, oxidation has no correlation with increased sulfur crude feeds to the unit; therefore, it is not considered to be included as a post-Modernization Project damage mechanism.

1.8.6 Caustic Cracking/Caustic Corrosion/Injection Point Corrosion

Caustic embrittlement is a form of stress corrosion cracking characterized by surface-initiated cracks that occur in piping and equipment exposed to caustic, primarily adjacent to non-post weld heat treated welds. Carbon steel, low alloy steels and 300 Series SS are susceptible. Susceptibility to caustic embrittlement in caustic soda (NaOH) and caustic potash (KOH) solutions is a function of caustic strength, metal temperature and stress levels. Chevron injects 5% caustic into the crude stream before the furnace to help manage HCL concentrations in the crude tower overhead system. There was no correlation established between post-modernization crudes, increased chlorides and whether the caustic injection would need to be modified. Normally, the desalter will desalt down to specification limits regardless of chlorides. Therefore, caustic cracking is not considered to be a post-Modernization Project damage mechanism.

1.8.7 Erosion / Erosion-Corrosion

Erosion is the accelerated mechanical removal of surface material as a result of relative movement between, or impact from solids, liquids, vapor or any combination thereof. In most cases, corrosion plays some role so that pure erosion (sometimes referred to as abrasive wear) is rare. It is critical to consider the role that corrosion contributes. For each environment-material combination, there is often a threshold velocity above which impacting objects may produce metal loss. Increasing velocities above this threshold results in an increase in metal loss rates.

In the Chevron Crude unit, erosion could be a damage mechanism factor post-Modernization Project if the throughput through the unit were to increase velocities in the high-temperature streams subject to sulfidation; however, Chevron has stated that crude velocities will not increase with the Modernization Project. Therefore, erosion should not be a post-Modernization Project issue in the crude unit.

1.8.8 Chloride Stress Corrosion Cracking

Chloride SCC cracks are surface initiated cracks caused by environmental cracking of 300 Series SS and some nickel base alloys under the combined action of tensile stress, temperature in an aqueous chloride environment. The presence of dissolved oxygen increases propensity for cracking. All 300 Series SS are highly susceptible, b) Duplex stainless steels are more resistant, c) nickel base alloys are highly resistant. Chloride content, pH, temperature, stress, presence of oxygen and alloy composition are critical factors.

Chevron states that there is no austenitic stainless steel fixed equipment or piping in the crude unit overhead system serving a pressure boundary function.

In addition, there is no post-Modernization Project chloride correlation, as described in *Appendix 4.3-MET*. Therefore this damage mechanism risk does not change with the post-Modernization Project conditions.

1.8.9 Short Term Overheating

Short term overheating is the permanent deformation occurring at relatively low stress levels as a result of localized overheating. This usually results in bulging and eventually failure. Affected materials include all fired heater tube materials and common materials of construction. Critical factors include temperature, time and stress. The damage usually is due to flame impingement or local overheating.

Like creep and oxidation, short term overheating is a damage mechanism that would be present only in the atmospheric tower charge furnace. Regardless of any potential increased duty on the charge furnace based on possible crude changes with the Modernization Project, tube skin temperature monitoring along with periodic infrared thermography scans ensures the furnaces will stay within existing tube metal design limits.

1.8.10 885°F Embrittlement

885°F embrittlement is a loss in toughness due to a metallurgical change that can occur in alloys containing a ferrite phase, as a result of exposure in the temperature range between 600°F to 1000°F. Affected materials include 400 Series SS (e.g., 405, 409, 410, 410S, 430, and 446). The alloy composition, particularly chromium content, amount of ferrite phase, and operating temperature are critical factors. Increasing amounts of ferrite phase increase susceptibility to damage when operating in the high-temperature range of concern. A dramatic increase in the ductile-to-brittle transition temperature will occur as a result of embrittlement. Damage is cumulative and results from the precipitation of an embrittling intermetallic phase that occurs most readily at approximately 885°F. The impact on toughness is not pronounced at the operating temperature, but is significant at lower temperatures experienced during plant shutdowns, startups or upsets. 885°F embrittlement can be found in any unit where susceptible alloys are exposed to the embrittling temperature range; therefore, most refining companies limit the use of ferritic stainless steels to non-pressure boundary applications because of this damage mechanism. Common examples include fractionator trays and internals in high-temperature vessels used in fluid catalytic cracker, crude, vacuum and coker units.

The type 410SS lining installed below tray 19 in the atmospheric tower and in the bottom of the vacuum tower is susceptible to 885°F embrittlement at normal operating temperatures. However, the susceptibility is based on the material of construction and the operating temperature of the tower, neither of which

should change resulting from Modernization Project conditions; therefore, 885°F embrittlement is not included as a post-Modernization Project damage mechanism.

1.8.11 Dissimilar Metal Weld (DMW) Cracking

Cracking of dissimilar metal welds occurs in the ferritic (carbon steel or low alloy steel) side of a weld between an austenitic (300 Series SS) and a ferritic material operating at high temperature. Affected materials include ferritic materials such as carbon steel and low alloy steels that are welded to the austenitic stainless steels, plus as any material combinations that have widely differing thermal expansion coefficients. Critical factors include the type of filler metal used to join the materials, heating and cooling rate, metal temperature, time at temperature, weld geometry and thermal cycling. Dissimilar metal welds have been used in piping in fired heater applications where the heater tube material changes from 5Cr or 9Cr to 300 Series SS.

As dissimilar weld cracking is strictly a function of material combination and high-temperature exposure, post-Modernization Project conditions should not influence this damage mechanism.

1.8.12 CO₂ Corrosion

Carbon dioxide (CO₂) corrosion results when CO₂ dissolves in water to form carbonic acid (H₂CO₃). The acid may lower the pH and sufficient quantities may promote general corrosion and/or pitting corrosion of carbon steel. Carbon and low alloy steels are affected. The partial pressure of CO₂, pH and temperature are critical factors.

CO₂ corrosion can occur in the overhead of the vacuum tower. Modernization Project conditions are not expected to increase any current levels of CO₂ in the overheads of the vacuum tower, based on increased sulfur in the crude feed.

1.8.13 Fuel Ash Corrosion

Fuel ash corrosion is accelerated high-temperature wastage of materials that occurs when contaminants in fuel form deposits and melt on the metal surfaces of fired heaters, boilers and gas turbines. Corrosion typically occurs with fuel oil or coal that is contaminated with a combination of sulfur, sodium, potassium and/or vanadium. The resulting molten salts (slags) dissolve the surface oxide and enhance the transport of oxygen to the surface to re-form the iron oxide at the expense of the tube wall or component. All conventional alloys used for process heater and boiler construction are susceptible. The concentration of molten salt forming contaminants, metal temperature and alloy composition are critical factors. The severity of damage depends on the type of fuel (i.e., the

concentrations of contaminants in the fuel), sulfur content and metal temperature.

Corrosion occurs by this mechanism only if the metal temperature is above the temperature of the liquid species formed and it is most severe where the temperatures are the highest.

Fuel ash corrosion is a damage mechanism that would affect the atmospheric and vacuum tower furnace tubes. However, it is a damage mechanism that originates in the fuel used to fire the furnace, not in the crude feed and Chevron has stated that they do not use any fuels containing these corrosive constituents; therefore, fuel ash corrosion is not considered to be a post-Modernization Project damage mechanism.

1.8.14 Ammonia Stress Corrosion Cracking

Aqueous streams containing ammonia may cause stress corrosion cracking (SCC) in some copper alloys. A water phase with ammonia or ammonia compounds must be present. Oxygen is necessary, but trace amounts are sufficient. Carbon steel is susceptible to SCC in anhydrous ammonia. Copper-zinc alloys (brasses), including admiralty brass and aluminum brasses, are susceptible. The 90-10CuNi and 70-30CuNi alloys are nearly immune.

Chevron has 70-30 Cu-Ni copper alloy exchanger tubes in the overhead of the atmospheric tower, however, this alloy is considered to be immune to ammonia stress corrosion cracking for all practical purposes. Therefore, any increase ammonia that is required post-Modernization Project to neutralize increase in crude tower overhead systems acids should not increase the susceptibility to ammonia SCC, particularly as there is already sufficient ammonia in the overhead to cause cracking of susceptible copper containing exchanger tubes and no failures due to the damage mechanism have been reported. Also, any failure of an exchanger tube in the crude tower overhead system would not result in failure of a pressure boundary component and release to atmosphere.

1.9 RISKS FROM RELEVANT DAMAGE MECHANISMS RELATED TO MODERNIZATION PROJECT OPERATIONAL CHANGES

1.9.1 General Methodology

This section discusses the methodology and rationale used to assess any newly created damage mechanisms in the crude unit resulting from the Modernization Project changes and/or damage mechanisms that would increase from previous baseline levels.

The first step in the damage mechanism review was to determine the post-Modernization Project operating conditions. This was done by: (1) conducting

interviews with Chevron Modernization Project personnel, technical department materials/corrosion and process personnel and personnel responsible for crude selection and purchases and (2) requesting and reviewing relevant documents needed for the assessment, including, (a) Chevron procedures and best practices, (b) industry standards, (c) process information and (d) crude selection, purchasing and blending procedures and practices, including representative assays of their intended post-Modernization Project crude blends.

The second step was to use the above information and data to independently assess the potential damage mechanisms resulting from the new, higher sulfur crude blends against the 66 damage mechanisms in API-571, *Damage Mechanisms Affecting Fixed Equipment in the Refining Industry*, (API-571, 2011) and any others, based on the reviewer's approximately 36 years of experience with damage mechanisms and environmental degradation of fixed equipment and piping in the refining and chemical industries. In addition to the above Chevron documents, other private communications, industry documents and published papers were reviewed in the assessment (see *Section 1.11, References*).

The third step of the analysis was to evaluate the potential impact of the identified damage mechanisms on fixed equipment, piping and piping components. Only those damage mechanisms resulting from a change based on post-modernization conditions were considered, i.e., damage mechanisms for existing conditions that are not projected to change with the Project were not evaluated.

1.9.2 Crude Unit

Given the potential for damage mechanisms in the crude unit resulting from the Modernization Project, the Reliability Analysis included an extensive evaluation of the possible damage mechanisms that could impact the crude unit post-Modernization Project. To assess the potential impact of the post-Modernization Project crude unit damage mechanisms, each identified damage mechanism was evaluated as to its anticipated location(s) in the crude unit and the specific equipment and piping it would affect. Those equipment and piping items were then evaluated against Chevron's current programs and practices related to equipment and piping reliability, published industry best practice documents and this reviewer's personal experience against anticipated post-Modernization Project changes to their operations to see if their mitigation plans were sufficient to prevent failures in post-Modernization Project operation. The equipment and piping reliability review included interviews with Chevron personnel and review of their mechanical integrity documents including: (a) Mechanical Integrity program procedures and working documents, (b) inspection procedures, (c) results of crude unit inspections, (d) Chevron Best Practices and (e) corrosion monitoring programs. The above was the methodology to assess impacted

damage mechanisms in the other units in Table A4.13-REL-4, but with differences in detail specific to those units.

In summary, the crude unit damage mechanism methodology and review process included the following attributes:

1. Verify characteristics of new crude blends
2. Verify what additional or increased damage mechanisms (DM) are anticipated with new crudes
3. Verify where the DM are expected to occur in the unit
4. Verify current condition and inspection/monitoring methods (present risk)
5. Verify future risk through a gap analysis of current and post-Modernization Project intended practices
6. Identify and recommend measures that could reduce risks associated with increased DM activity that could result from the Modernization Project

The above steps are generally consistent with the methodology that Chevron followed in their internal reliability review, based on review of their document submittals.

1.9.2.1 Process Description

Crude units distill crude oil to produce up to nine distillate streams and vacuum residuum. The crude oil is heated, desalted and split into various product streams that are sent to intermediate tankage or to downstream processing units as feed.

Crude units consist of the following overall systems:

- Crude feed booster pumps
- Primary heat exchanger train
- Desalter
- Flash drum
- Secondary heat exchanger train
- Atmospheric furnace and column
- Naphtha stabilizer C-1190
- Vacuum furnace and column

- Vent gas recovery
- Sour water

The desalter removes water, salts and suspended solids from the crude oil prior to entering the flash drum. Chloride salts can decompose to form hydrogen chloride (HCl) in the atmospheric and vacuum furnaces. HCl forms hydrochloric acid in the presence of water. This acid can severely corrode atmospheric and vacuum column overhead systems. Salts and solids foul heat exchanger and furnace tube surfaces resulting in reduced heat transfer and higher-pressure drop in these units.

Crude oil contains as much as 2% water, which is usually carried in an emulsified form. Sources of water are formation water, water used in field recovery, seawater picked up during shipment, and water from tank bottoms. Salt content of crude can be as high as 10-40 pounds per thousand barrels (pptb). Periodically, it may contain as high as 200 pptb. Salts found in crude oil are primarily sodium chloride with smaller amounts of calcium, magnesium, iron, and aluminum chlorides, sulfates and bicarbonates. Suspended solids, sand, drilling mud, high melting point waxes, and corrosion products may also be in the crude. These contaminants are removed by desalting to the 0.5-1 pptb level.

Desalted crude oil normally contains about 0.1%-0.3% water. This water contains salt. The purpose of the flash drum is to vaporize (flash) the light ends and any remaining water in the desalted crude oil. This reduces fouling in the downstream exchangers since any residual salt in the flash bottoms will plate out on the downstream exchanger tubes. The secondary heat exchanger train further raises the temperature of the flashed crude from the flash drum to approximately 520-525°F before entering the atmospheric furnaces.

The atmospheric furnaces and column control the unit crude feed rate, control furnace firing and raises the temperature of the feed to approximately 700°F before entering the crude tower. The crude tower distills the product streams to meet product specifications and provides feed to the vacuum furnace. The primary purpose of the atmospheric furnace is to provide a controlled source of heat to the crude oil. The furnace heats the crude oil to about 675°F and vaporizes it. The mixture then flows to the flash zone of the column. Steam superheating, steam generation, and boiler feed water heating coils are provided in the furnace convection section above the crude oil coils. These coils provide additional heat recovery and improve overall efficiency of the furnaces.

The atmospheric column accepts crude in the flash zone from the crude furnace at a temperature of approximately 675°F. In the flash zone, the vapor and liquid separate. The vapor passes up through the wash oil section, above which column trays distill the fractions according to their boiling points. The liquid falls down

through the stripper section toward the bottom of the column for further processing in the vacuum column. The atmospheric column temperature decreases progressing up the column from the flash zone. Vapor advancing up the column contacts liquid coming down from the trays above. The liquid and vapor become richer in light components as they rise. Consequently, the liquid removed at the upper trays yields products with lighter boiling ranges.

The atmospheric column sidecut streams are:

- First Sidecut (jet)
- Second Sidecut (jet)
- Third Sidecut (diesel)
- Fourth Sidecut (light gas oil)

The four sidecuts are drawn from the atmospheric column. The first and second sidecuts go to the Jet Hydrotreater (JHT) as hot feed, the third sidecut goes to the Diesel Hydrotreater (DHT) as hot feed, and the fourth sidecut can go directly to the TKN Unit as a hot stream, or cooled and sent to TKN cold feed tankage.

The atmospheric overhead section cools and separates hydrocarbon and water vapors that were not condensed in the column. All of the stripping steam that was injected at the bottom of the column rises to the top and is condensed. Some of the hydrocarbon liquid is condensed and some remains in the gas phase. The hydrocarbons remaining in the gas phase are the lightest ends.

The bottom section of the atmospheric column collects the atmospheric residuum prior to further processing in the vacuum column. Residuum contains liquid that was not vaporized in the flash zone and excess wash oil. Liquid that was not vaporized in the flash zone flows through the stripper section to the bottom compartment.

The stabilizer column processes atmospheric column overhead (naphtha) from the atmospheric column reflux drum that is not required for atmospheric reflux. It removes butanes and lighter components from the naphtha.

The vacuum furnace and column system recovers vacuum gas oils from the atmospheric residuum. The primary purpose of the vacuum furnace is to provide a controlled source of heat to the atmospheric residuum. There, it is heated to approximately 775°F and flows to the flash zone of the column. The vacuum furnace vaporizes the residuum prior to its entry into the column. Vapor from the top of the vacuum column contains steam, light hydrocarbon, and H₂S.

Three sidecuts drawn from the vacuum column are:

- 6 Sidecut (light gas oil)
- 7 Sidecut (heavy gas oil)
- 8 Sidecut (heavy gas oil)

The vent gas recovery system compresses the overhead gas from the vacuum column and assists in maintaining the vacuum. It recovers low-pressure sour gas streams from the complex and provides additional flare gas recovery from relief line gases

The Sour Water system includes the following equipment:

- Sour Water Degasser
- Fin Fan Coolers
- Sour Water Pumps

The sour water degasser serves as the intermediate destination for all of the sour water produced in the LSFO complex. Sour water streams include those from the JHT, DHT, NHT units and V-3211, and V-1160 in the crude unit. The sour water degasser is also a separate system that can run with the crude unit shut down. The degasser allows light hydrocarbons and H_2S to flash off of the sour water streams at low pressure before being routed to sour water tankage and separates heavier hydrocarbons and water.

1.9.2.2 General Corrosive Constituents in Oil

The composition of crude oil is important to crude unit operations, but it cannot be changed. It is set by the oilfield it came from and the production operations used to gather the oil and make it suitable for shipment. Crude oil composition varies from tanker to tanker. For minimum refinery corrosion, the charge to the crude distillation unit should be dry (no liquid water) and contain minimum impurities. Some impurities, if present in the crude charge, can cause corrosion problems in other downstream units.

The constituents in oil that cause corrosion are sulfur compounds, salt water, inorganic and organic chlorides, inorganic and organic acids, and nitrogen (which forms cyanides and ammonia bisulfides).

Sulfur compounds are contained in crude oil as H_2S , mercaptans, and complex organic sulfur compounds generally present in the range of 0.1 to 5.0 wt. % sulfur. Salts, including sodium, calcium and magnesium chlorides in water, are dispersed in the crude oil. Naphthenic acids are mixed organic acids present in crude oil in the range of 0.03-0.40 wt.%. Organic chlorides are usually picked up in the field due to the use of chlorinated solvents for dewaxing producing wells

and pipelines. The sulfur compounds found in crude oil are shown in Figure A4.13-REL-4.

As can be seen in Figure A4.13-REL-4, a wide variety of sulfur compounds can be present in crude oil. The corrosivity of a specific crude oil, based on its total sulfur content, is difficult to predict due to variations in the degree of decomposition of sulfur compounds during processing. One approach to approximating the corrosiveness of a crude oil is to measure the amount of H_2S generated as a crude oil sample is heated to several temperature levels in the 400-800°F range. High sulfur crude oils, such as Kuwait and Merey, usually require materials resistant to sulfur only in high-temperature areas, such as heaters and the bottom of the crude distillation tower. The severity of corrosion often depends on the type of sulfur in the stream, the temperature level, and stream velocity. Carbon steel with a reasonable corrosion allowance is usually adequate to resist sulfur corrosion below 550°F. Chevron has adopted the API-RP-939C recommendation that carbon steel (fully killed⁴ with a silicon content greater than 0.1 wt.%) in new construction is a suitable material in sulfidation service up to 525°F.

Crude oil containing more than about 0.05 ft.³ dissolved H_2S per 100 gal of oil is called “sour”. However, crude 0.1 containing less than 0.5 ft.³ of H_2S per 100 gal of oil is not corrosive to steel in petroleum processing equipment (Bogaerts, 1998). The compounds shown in Figure PS-TR-2 decompose thermally, during processing, into constituents such as H_2S and mercaptans (organic sulfur compounds). In sufficient quantities (above ~0.2 wt.%), the compounds can be corrosive to carbon and low-alloy steels at temperatures above ~480°F to 550°F and up to 850°F. Above 850°F, corrosion rates decrease if the pipe inner diameter coke up; otherwise, the corrosion rates continue to increase.

Crude oils charged to a crude heater contain varying amounts of salts such as sodium, magnesium and calcium chlorides, along with basic sediment and water (BS&W). As the crude oil is heated, magnesium and calcium chlorides hydrolyze to hydrochloric acid (HCl) in the heater and tower. This causes no problem in the middle and lower sections of the tower since HCl is not corrosive at temperatures above the water acid dewpoint. Corrosion from HCl usually occurs in the upper tower and the tower overhead system where the temperature is below the water dew point of about 240-280°F. The water dew point can vary considerably from one crude unit to another depending on the water partial pressure and could possibly be as high as 300°F. Another factor involved when excessive amounts of HCl are generated in the crude tower is that HCl is continuously regenerated by H_2S unless neutralized by ammonia. Therefore, ferrous chloride formed by the reaction of iron and HCl in turn reacts with H_2S to form iron sulfide and HCl. The advantages of maintaining the lowest possible HCl level in the crude upper tower

⁴ “Steel that has been deoxidized sufficiently for it to lie perfectly quiet when poured into an ingot mold” (U.S. Steel Corporation, 1971).

Sulfur Compounds in Crude Oil

and overhead system is readily evident since even small amounts of HCl are regenerated in the presence of H_2S until the free HCl is neutralized by ammonia addition in the overhead line. The usual approach to controlling acid attack in the overhead system is the addition of neutralizing agents and corrosion inhibitors.

Laboratory studies show that there are widely different evolution levels of H_2S and HCl depending on the type of mercaptans in the crude, the salt level, and the composition of the salts. Some oils are much more susceptible to the evolution of hydrochloric acid than others having similar total chloride contents, which indicates that there are other factors besides the chloride concentration that affect the hydrolysis of these salts.

Hydrochloric acid evolved in distillation is formed principally as a result of the hydrolysis of magnesium chlorides. Calcium and sodium salts do not materially contribute to the formation of hydrochloric acid from hydrolysis of salts. Most of the magnesium chloride hydrolyzes in the temperature range of 400-600°F. At 600°F, calcium chloride, and to a lesser extent sodium chloride, also begin to hydrolyze. Various acidic materials in the crude oil such as naphthenic acids and phenols will promote the evolution of hydrochloric acid under distillation conditions. The undesirable impacts arising from the presence of salts and BS&W in crude oil charge stocks can be classified into five principal categories:

1. Salt deposits in exchangers and furnaces
2. Evolution of corrosive hydrochloric acid
3. Contamination of residual products.
4. Reduced capacity and/or fuel efficiency due to heating water
5. Erosion of equipment by sediment.

The hydrochloric acid generated in the crude is extremely corrosive and makes it necessary to inject ammonia into overhead lines to minimize corrosion damage. Ammonium chloride formed as a result of the neutralization reaction is itself corrosive however, and tends to plug up condensers and columns in the overhead system.

Assays of crude should be current. Recovering heavier oils from an oil field changes the sulfur and organic acid contents. Since total acid numbers and weak acid numbers do not differentiate between naturally occurring naphthenic acid and some acids caused by oxidation, it becomes difficult to determine whether or not naphthenic acid corrosion will be a problem. The increase in crude-specific gravity makes the determination of the total acid number more difficult and increases the probability of error.

Organic acids (e.g., naphthenic acid) can cause severe corrosion above ~450°F (although attack has been seen as low as 340°F in turbulent areas) if the neutralization number exceeds 2.0 mg of potassium hydroxide per gram (mg KOH/g). The naphthenic acid content is generally determined by titration with KOH, as described in ASTM4 D974 or D664 for neutralization value. This value (called the neutralization number) is expressed in mg of KOH required to neutralize the acid constituents present in 1g of sample. Crudes with neutralization numbers in excess of 0.5 mg KOH/g can cause serious corrosion problems in the vacuum tower flash zone. When inorganic chlorides (e.g., ammonium chloride) and organic chlorides collect (usually in the tops of columns and equipment connected to the tops of columns), mild to severe corrosion can occur. When organic nitrogen compounds in the feed exceed 0.05 wt.% (500 ppm), cyanides and ammonia can form, depending on the temperature. These compounds collect in the aqueous phases and cause corrosion of certain materials.

1.9.2.3 Corrosion and Materials Selection (General)

Alloy selection in crude units is made to control and mitigate the expected damage mechanisms found in most crude units, including sour water corrosion, acidic sour water corrosion, HCl corrosion, ammonium chloride corrosion (sour water corrosion), wet H₂S damage as SSC, HIC, SOHIC and high-temperature sulfidation. Other crude unit HCl damage mechanisms specific to individual equipment include creep/stress-rupture/oxidation of furnace tubes in fired heaters, ammonia SCC in brass exchanger tubes, etc.

The crude unit damage mechanisms and the materials selected to resist those damage mechanisms can be divided into broad physical areas of: (1) wet H₂S cracking; (2) acidic/alkaline corrosion (including HCl corrosion, sour water corrosion, acidic sour water corrosion) and (3) high temperature sulfidation corrosion (Figure A4.13-REL-5).

In the feed preheat section of the unit, carbon steel is generally used up to approximately 500°F. At temperatures greater than about 500°F, hot H₂S corrosion (high-temperature sulfidation) becomes active and chromium-molybdenum alloys of increasing chromium are needed to resist the sulfidation corrosion. In increasing order of resistance to high-temperature sulfidation, based on temperature and the amount of sulfur, are carbon steel, 1-3Cr, 4-6Cr, 7-9Cr, 12Cr and 18-8 stainless steel. The 1-9 Cr alloys are usually used for piping. 12Cr is typically used as a cladding in the atmospheric and vacuum towers.

Source: Chevron (T85)

Figure A4.13-REL-5
Chevron Refinery Modernization Project EIR
Locations of Damage Mechanisms in Crude Units

In the overhead system of an atmospheric tower, where acidic and alkaline corrosion is active, carbon steel is the typical material of construction, except for thin-walled components such as exchanger tubes, injection point inserts, etc. Carbon steel would not be resistant to the overhead environment if operational/process means to protect it from corrosion were not also used, including water-washing to dilute acids and the use of corrosion inhibitors to minimize corrosion rates. Wet H₂S cracking is normally not an issue in crude unit overhead systems due to the low hardness of carbon steel equipment and piping and carbon steel usually provides satisfactory service if properly fabricated.

1.9.2.4 Crude Feed

The crude feed system from tankage to the desalter of the crude unit is typically carbon steel construction. The initial corrosion control device used in a crude unit is a desalter. The crude is first desalted to minimize acidic corrosion from hydrolyzed salts in condensed steam vapors that go overhead in the atmospheric fractionator column.

As the crude is heated above 500°F in the pre-heat exchangers and in the fired heater, corrosion can occur from sulfidation as a result of the breakdown of sulfur compounds, as described in earlier in *Section 1.7.1*. These higher temperatures may require the use of chrome-moly materials, based on predicted corrosion rates using the McConomy curves. Sulfidation can occur in the atmospheric column and vacuum column; it is typically most severe at the column “flash zone” (inlet from the fired heater) as a result of turbulence from high velocities and flashing. The increased potential for corrosion in these zones is mitigated by the use of resistant alloys such as 12 Cr or 300 SS as cladding material. Condensing water containing H₂S and salts can cause corrosion in the overhead system of the atmospheric and vacuum column; however carbon steels can be typically used with supplemental corrosion control methods such as aforementioned water wash and corrosion inhibitors.

Removal of salts from the crude is important to avoid corrosion and plugging of the overhead system. Any plugging is normally caused by ammonium chloride salts. Sodium chloride, which is quite soluble in hot water, is easily removed. Magnesium chloride, not as easily removed as sodium chloride, hydrolyzes to hydrochloric acid. Desalting to 1 ptb can keep tower overhead condensates under 50 ppm of hydrochloric acid; however, 50 ppm hydrochloric acid can still be quite corrosive to carbon steel. Therefore, additional corrosion control measures are used to mitigate the impacts of acidic chlorides, such as water washes and corrosion inhibitors. Another technique to reduce hydrolysable chlorides is to use caustic (sodium hydroxide) injection after the desalter. The sodium hydroxide converts corrosive magnesium chlorides to the more harmless sodium chloride. The injection amount is guided by the amount of salt in the overhead condensate.

1.9.2.5 Overhead Systems

The top of the tower is subjected to water condensation that contains hydrogen chloride, ammonia (if injected for corrosion control), and H_2S . Corrosion rates can be severe if the chloride content is high. For this reason, Monel 400 is often used as a tower lining and as a tray material. Monel 400 is resistant to these waters below 250°F; however, corrosion can occur if the ammonia exceeds 3 wt.%, or if the pH becomes too high.

Corrosion protection in the atmospheric tower overhead system is achieved by neutralizing the water condensate to a pH value of 6 to 6.5 and by using an inhibitor. Neutralizers include ammonia and neutralizing amines. There are pros and cons associated with each neutralizer. Control of pH with ammonia is difficult because of the strong impact that hydrogen chloride or ammonia has on condensate pH if too little or too much ammonia is used. Neutralizing amines buffer the water so that pH control is easier over a wide range of amine concentrations. Neutralizing amines are soluble in both water and hydrocarbon. If the amine chloride concentration in hydrocarbon is high, the amine chloride can return to the fractionator and cause chloride corrosion.

The neutralizers are typically injected in the fractionator overhead line in order to be present when the dew point of hydrochloric acid is reached. It is important to use a corrosion resistant quill to inject neutralizers or inhibitors because drip injection can cause dissolution of the protective scale on the inside of the pipe, which can result in corrosion and erosion in that area. For this reason, the pipe spool including the injection quill will often be manufactured from a corrosion resistant alloy (CRA) for a distance upstream and downstream of the water wash quill in case corrosive salts form at the injection point. Often however, neutralization is not accomplished, and severe corrosion from hydrochloric acid still occurs at the dew point. Hastelloy C-276 is a widely used alloy for aggressive, acidic chloride environments. Chevron Richmond has a C-276 weld overlay spool piece installed in the overhead piping to mitigate this localized corrosion at the water injection point.

Materials used in the overhead condensers vary with the source of the cooling water, the amount of chlorides, and the success of inhibitors, pH control, wash water, etc. For refineries with brackish or salt water cooling, the use of titanium tubes is economical since carbon steel cannot be used. Titanium is cost competitive with stainless steels (SS's), Monel 400, brasses, and copper-nickel alloys. If ammonium chloride forms and plugs the hot areas, pitting of copper base alloys can occur. Brasses such as admiralty brass have been used successfully where waterside velocities are controlled to less than 8 ft./s, and the ammonia content is not high enough to corrode or crack the brass (pH below 7.2). Copper-nickel alloys are much more resistant to ammonia but will corrode if the H_2S content is high. Duplex stainless steel alloys, as well as ferritic stainless

steels, have experienced under-deposit corrosion in overhead systems. Austenitic alloy 904SS has also performed well. Carbon steel is used only where there is very careful cooling water control.

H₂S damage as SSC, HIC and SOHIC are also potential damage mechanisms in atmospheric tower overhead systems. However, in the absence of cyanides, which are normally not present in crude units, damage from H₂S cracking is rare, based on the use of low strength (low hardness) carbon steels and the lack of HIC/SOHIC cracking in carbon steel piping materials. However, H₂S damage, while rare, can still occur and should be included in a refinery inspection program.

1.9.2.6 Crude Heater and Distillation Columns

After the crude passes through the desalter, it goes into the crude heater where the sulfur compounds are partially decomposed thermally. When the sulfur exceeds ~0.2 wt.%, corrosion of carbon steel can become excessive. The higher the chromium content in the alloy, the more resistant the alloy is to sulfidation. In general, furnace tubes and piping are manufactured from 5Cr-½Mo steel for sulfur-bearing crudes when the temperature exceeds ~550°F and 9Cr-1Mo when the temperature exceeds ~750°F.

The temperature at which excessive corrosion of carbon steel occurs is a function of the characteristics of the sulfur compounds in the crude. This temperature can be estimated by measuring the amount of H₂S evolved as a function of temperature. The amount of H₂S evolved vs. temperature varies widely, and there is no relationship to the wt.% sulfur. Since H₂S release data are rarely available, materials selection is usually based on wt.% sulfur, although the correlation with corrosion rates is only very general. Recent studies indicate that direct reaction of the organic sulfur compound with the metal surface is the predominant mechanism of high-temperature sulfidation. The McConomy curve is the most widely used tool used to predict corrosion rates and material selection to resist high-temperature sulfidation in the absence of hydrogen.

The 5Cr-½Mo alloy, commonly used in furnace tubes, corrodes at a measurable rate with a design life of typically at least 10 years or longer. Even though metal temperatures are higher than the process temperature in furnace tubes, corrosion rates are always reported as a function of the process temperature. Therefore, furnace tubes tend to corrode at higher rates than piping for the same process temperature.

Columns are usually clad with 12Cr above ~550°F (290°C). Some refiners use cladding above 450°F to minimize maintenance and to minimize fouling from corrosion products. The 12Cr cladding is essentially immune to high-temperature sulfidation attack and is used due to the long design life of

atmospheric columns of 20 years. Pressure-retaining parts of 12Cr are usually limited to 650°F to avoid problems resulting from 885°F embrittlement. The majority of attack occurs in the flash zone where the feed enters the column and partially flashes to vapor and this is where 12 cladding is typically installed.

When naphthenic acids are present in sufficient quantities, carbon steel and low Cr alloys up to 12% chromium can be severely attacked. The austenitic stainless steels such as Type 316/317 are normally resistant in the same service. The corrosion rate of naphthenic acid-containing oils shows an increase in corrosion rates as a function of temperature. The most severe corrosion occurs at ~550°F because the naphthenic acids concentrate in these streams at that temperature. Corrosion of type 316 SS has occurred in vacuum unit transfer lines containing a high naphthenic acid content with 15 to 40% vaporization. To minimize attack, both vaporization and velocity should be kept at a minimum. Type 316L (UNS S31603) SS, preferably with a minimum of 2.5% molybdenum, is usually used above 450°F for naphthenic acid service. Where neutralization numbers, vaporization, and velocities are high, high-molybdenum alloys such as type 317L (UNS S31703) SS may be required. Chevron Richmond does not process naphthenic acid crudes or crude blends.

In general, sidecut stripper columns corrode much less than the main fractionators for the same temperature. The corrosive sulfur compounds tend to move to the bottom of the main fractionator with the liquid, and the H₂S moves to the overhead of the main fractionator. Sidecut strippers are usually not clad until the process temperature exceeds 650°F. Sometimes, the heavy gas-oil sidecut contains naphthenic acid, which can cause enough corrosion that iron enters the fluid catalytic cracker unit feed.

Vacuum columns should be treated separately from atmospheric columns. The inlet line from the charge vacuum tower furnace and the inlet area of the tower usually corrode at the highest rate. The overhead vacuum system will corrode if chlorides are present. This corrosion is reduced if corrosion in the atmospheric tower overhead is reduced by desalting, caustic injection, or both.

Naphthenic acid corrosion can be quite severe in vacuum towers when high TAN crudes are processed. Crudes with total acid numbers (TAN) over 2.0 mg KOH/g have corroded type 316 SS in the inlet areas. At times, type 317 (UNS S31700) SS, 904L (UNS N08904), or other corrosion resistant alloys are needed.

Heat exchangers are treated in a manner similar to columns (i.e., 12Cr clad shells and channels and 5Cr-½Mo tubes are usually used above 550°F. When selecting materials for exchangers, one must take into account crevices, changes in direction, and actual tube metal temperatures (since the tubes are exposed to fluids of different temperatures).

1.9.2.7 Crude Selection, Purchasing and Blending

The first step (described above) in the damage mechanism review assessment was to understand Chevron's crude selection/purchasing process and how the post-Modernization Project crude characteristics would potentially change with respect to crude unit damage mechanisms.

The Facility purchases crude and gas oils in the global market place and transports these feed-stocks to the Facility for processing into transportation fuels and lubricant base oils. Generally, different crude oils are blended and then fed into the crude unit, where they are divided into fractions for processing into various product streams. Imported gas oils, as well as gas oils produced by the crude unit, are directly fed to various Facility units for conversion into end products. Additionally, the Facility typically imports small amounts of material known as blend stocks. These materials are not considered Facility feed stocks since they are not processed by the Facility; instead they are blended with other materials into finished products that leave the Facility.

The Modernization Project increases the Facility's ability to accept crude oil blends with higher sulfur content that it cannot currently process; however, the Modernization Project also provides the Facility with increased flexibility to process higher-sulfur crude oil blends which may fall at either the higher or lower end of the intermediate-light gravity range. The Modernization Project will enable the Facility to increase the sulfur removal limit from 600 to 900 long tons per day (lt/d). The 900 lt/d limits equates to an approximate 3 wt.% sulfur content in crude oil blends (Chevron, 2013b; Chevron, 2013a; Chevron [n.d.9])

It was necessary to understand the Modernization Project expected crude blends prior to conducting the reliability and damage mechanism review, plus the projected sulfur content and other potential feed constituents that can have an impact on damage mechanisms. The Chevron Oils Planning Department was interviewed, and Chevron's crude acceptance procedures were reviewed (Chevron [n.d.4]) to understand what typical crudes were planned and how blend decisions were to be made, based on post-Modernization Project conditions.

The result of this review showed that Chevron has a sophisticated quality assurance process for accepting new crude sources that include the effects of evaluating different blend ratios in arriving at an acceptable crude blend. The process is software driven and includes provisions that allow different refinery personnel with specific, relevant responsibilities to "fail" recommended crude blends, which then require further review. Chevron's metallurgical engineer is one such person who can "fail" a recommended crude or crude blend recommendation, based on metallurgical/corrosion concerns. Also, Chevron's Management of Change (MOC) procedure includes changes in crude chemistry as an initiator of a MOC review.

As previously stated, a P50 (benchmark) and a P90 crude oil blend, with higher-sulfur levels, were defined by Chevron for the post-Modernization Project conditions (Chevron [n.d.6]). This defined crude oil blend was used to determine the impacts of potential damage mechanisms in the crude unit. The two crude blend cases considered in this Reliability Analysis and damage mechanism analysis were a 2.38 wt. % sulfur P-50 case and a P-90 case, as described in earlier sections of this Appendix.

There are considerations regarding the potential impacts of various constituents in the crude blends in their influence on damage mechanism issues, for example, constituents in crude oils widely known to initiate or influence damage mechanisms include chlorides, sulfur, mercaptans and nitrogen. Their influence on damage mechanisms is described elsewhere.

The influences of other crude constituents on damage mechanisms, including metals, are not as well established as those above. Therefore, an analysis was conducted to determine if there was any correlation between crude sulfur wt. % and other potentially corrosive constituents such as nitrogen, chlorides, acids, reactive sulfur, metals, etc. (Appendix 4.3-MET). The analysis also investigated if there was a correlation between the same corrosive constituents and API gravity. The analysis was done by conducting a literature search to evaluate whether nitrogen, metals, “reactive sulfur species” (mercaptans), acid, and chlorides content would likely increase with increased crude oil sulfur content or with decreasing gravity. Public crude oil data was obtained from various agencies and institutions and statistically evaluated to investigate the potential relationship between the crude oil sulfur and API gravity vs. concentrations of nitrogen, metals, reactive sulfur species (mercaptans), acid, and chlorides.

The analysis for acids is discussed further below, for metals in Section 1.9.2.7.2, and for the other constituents evaluated, the conclusions are as follows:

- A weak statistical relationship was found between nitrogen content and sulfur content of crude oils. Thus, slight increases in nitrogen content of crude oils could be reasonably foreseeable with increasing sulfur content crude oils expected with the Modernization Project, given the weak correlation.
- A moderate to strong statistical relationship was found between API gravity in the intermediate range and nitrogen content of heavier crude oils (between 28 and 40 API). As the baseline average API was 33.7, the potential for processing lower API crude oils with the Modernization Project could result in reasonably likely increases in nitrogen content.
- No statistical relationship was found between mercaptan sulfur content and sulfur content. Thus, increases in mercaptan sulfur content of crude oils are

not reasonably likely to occur with higher sulfur content crude oils expected with the Modernization Project, given the lack of a strong correlation.

- No statistical relationship was found between mercaptan sulfur content and gravity. Thus, increases in mercaptan sulfur content of crude oils are not reasonably likely to occur with lower API crude oils expected with the Modernization Project, given the lack of a strong correlation.
- No statistical relationship was found between salt content and sulfur content. Thus, increases in salt content of crude oils are not reasonably likely to occur with higher sulfur content crude oils expected with the Modernization Project, given the lack of a strong correlation.
- No statistical relationship was found between salt content and gravity. Thus, increases in salt content of crude oils are not reasonably likely to occur with lower API gravity crude oils expected with the Modernization Project given the lack of a strong correlation.

1.9.2.7.1 Crude Acceptance Process

The Facility's Crude Acceptance Process helps reduce the potential for equipment damage. Before a crude is accepted for processing in the Facility, it is reviewed by a number of specialists with the aid of the protocol called for by the Crude Acceptance Process, the crude assay database, and by screening criteria (parameters) that is part of the process. At the Facility, a crude is screened with the expectation that it would not be the sole source of feed to the crude unit. Crude blends are assessed in the context that any particular crude is blended in with an ongoing, familiar crude blend.

The Facility states that typically each year, five to six new crude blends will be evaluated for the Facility; in some years, perhaps as many as ten blends will be evaluated. Specialists involved in assessing the crudes include planning experts, processing specialists, and metallurgy/reliability specialists. While some of the crude screening parameters are chosen based upon processing and economic considerations, some parameters are relevant to the damage mechanisms discussed in this report.

The most relevant parameter for the Modernization Project is the sulfur content. Currently, the HP units all have feed sulfur limits based on hydroprocessing Best Practice HP-002 (Chevron [n.d.3]), which controls the H₂S partial pressure in these units. This, in turn, may restrict the crude purchases or alter the crude blend. In the future, additional post-Modernization Project crude sulfur level screening will be done as per the Modernization Project Reliability Program. The Chevron Reliability Program specifies a trigger for a reliability review when the crude oil processed at the refinery reaches 2.25 wt. % sulfur on an annual average and again when it reaches 2.75 wt. %.

As described in Appendix 4.3-MET, no statistical relationship was found between acidity and sulfur content. Thus, increases in acidity of crude oils are not reasonably likely to occur with higher sulfur content crude oils expected with the Modernization Project, given the lack of a strong correlation. In contrast, a weak statistical relationship was found between API gravity in the intermediate-light gravity range (28 and 40 API) and acidity. Thus, it is reasonably foreseeable that slight increases in acidity of crude oils could occur with lower API crude oils expected with the Modernization Project given the weak correlation.

However, Chevron's crude screening criteria include TAN limits (whole crude = 0.3 and sidecut 1.5) which in effect allow very little, if any, acidic crudes to be processed; therefore damage mechanisms related to acidity would not be expected to increase with the Modernization Project given this existing limit.

Other parameters that are reviewed but are not necessarily considered constraints include nitrogen and certain metals.

1.9.2.7.2 Metals Analysis

The crude correlation analysis conducted (Appendix 4.3-MET) concluded that it is possible that the metal content of crude oils processed by the Facility could increase slightly for some metals if the Modernization Project is implemented.

Heavy metals are known to be constituents of crude oils and their influence on damage mechanisms was raised as a potential post-Modernization Project crude selection issue. Metals that are known to influence corrosion and materials degradation in refining and chemical industry settings include vanadium, cadmium, mercury, nickel, copper and zinc. Therefore, a correlation analysis was conducted to investigate whether or not a correlation existed between metals in crude and crude wt. % sulfur or API gravity. This analysis is presented in Appendix 4.3-MET. Public crude oil data obtained from various agencies and institutions was evaluated to investigate the potential relationship between the crude oil sulfur concentration and gravity to the concentration of barium, iron, magnesium, nickel, titanium, vanadium, and zinc. Little data on mercury, lead, copper, cadmium, and arsenic was available to construct meaningful analysis and therefore, the statistical relationship between these metals and sulfur or gravity was not evaluated. Appendix 4.3-MET concludes with the following related to metals:

- No statistical relationship was found for the dependence of barium, calcium, magnesium, titanium, and zinc on sulfur (i.e., concentrations of metals did not vary with sulfur concentrations).
- A weak statistical relationship was found for the dependence of iron, nickel and vanadium on sulfur concentration. Thus, it is reasonably foreseeable that slight increases in iron, nickel and vanadium content of crude oils could

occur with higher sulfur content crude oils expected with the Modernization Project, given the weak correlation.

- No statistical relationship was found for the dependence of barium, titanium, and zinc on gravity (API).
- A weak statistical relationship was found for the dependence of calcium, iron, magnesium, nickel, and vanadium on gravity (API). Thus, it is reasonably foreseeable that slight increases in calcium, iron, magnesium, nickel and vanadium could occur with lower API crude oils expected with the Modernization Project given the weak correlation.

Of the above listed metals that are known to influence corrosion and materials degradation in refining and chemical industry settings (vanadium, cadmium, mercury, nickel, copper and zinc), only the potential increases in nickel and vanadium were initially believed to potentially impact equipment degradation in either the existing setting or post-Modernization Project. Vanadium can result in rapid corrosion of metals and alloys in furnaces and heater through the condensation of vanadium pentaoxide salts, commonly referred to as low melting point salt corrosion. This damage mechanism typically occurs when using heavy, waste hydrocarbon products as fuels that contain vanadium, i.e., “bunker fuels.” Chevron has stated that they do not use these hydrocarbon sources as fuels; therefore, material degradation due to metal wastage from vanadium pentaoxide should not be a problem, either existing setting or post-Modernization Project.

Nickel is known to act as a catalyst in promoting coke formation in heater tubes in certain hydrocarbon cracking processes. However, nickel that catalyzes coke formation occurs as an alloying element of the cracking tubes themselves, as opposed to nickel in a hydrocarbon; therefore, material degradation in Chevron heaters due to coke formation from nickel is not expected either.

Therefore, based on the above technical analysis and the results of the metals vs. crude correlation (described above), it is not likely that the metal content of crude oils processed by the Facility would increase metal related damage mechanisms if the Project is implemented.

1.9.2.8 Impacted Damage Mechanism Discussion

1.9.2.8.1 Wet H₂S Damage

Chevron has stated that post-Modernization Project conditions likely will involve somewhat higher levels of H₂S in the overhead system of the atmospheric column (Chevron, 2014a). How much increased post-Modernization Project H₂S will be in the overhead was not quantified; however, Chevron based their wet H₂S impact analysis on an assumed H₂S change in overhead greater than a 10% threshold.

Based on Chevron's "Risk Management of Wet H₂S Cracking in Process Plants," (Chevron, 2005b), a 10% threshold increase in H₂S loading defines the criteria for a "significant" process change that would warrant an internal inspection. This is a conservative assumption requiring Chevron to conduct wet H₂S inspections following the introduction of post-Modernization Project crudes.

The impact of increasing H₂S, in the atmospheric tower overhead can be anticipated but its actual impact will need to be verified after post-Modernization Project operation. The impact of increased H₂S will be to directionally increase the amount of dissolved H₂S in the overhead system, particularly in the accumulator water drum. Increased H₂S can result in sour (NACE MR0175) conditions of an initially non-sour system. However, the crude atmospheric tower overhead system is currently sour, as defined by NACE as <0.05 psia H₂S partial pressure in the vapor phase or greater than 50 ppmw H₂S in a water phase.

H₂S is not corrosive at atmospheric tower overhead temperatures until it is contacted by liquid water. Therefore, an increase in H₂S in the overhead vapor will not impact equipment or piping until it reaches the overhead water injection point where it will tend to dissolve in the water phase. Any increase in the acidity (due to dissolved H₂S) of condensed water in the overhead system could potentially be negated by the present use of neutralizing chemicals (ammonia) to control overhead corrosion. Chevron's Atmospheric Overhead Corrosion Control Best Practice document (Chevron, 2005a) stipulates maintaining the overhead accumulator water in the 7.0-7.5 pH range using ammonia injection, with pH being controlled by use of an on-line pH analyzer, a board mounted controller for ammonia injection and a closed loop pH control system. Therefore, if properly maintained and controlled, any increase in H₂S in the overhead system should not increase the severity of wet H₂S damage as cracking (or sour water corrosion) in the overhead injection system should maintain the pH of the accumulator water at current control limits, unless other cracking species increase, such as cyanides, which are not anticipated

There are several other reasons why an increase in the H₂S content of the atmospheric overhead system should not impact H₂S-related, aqueous damage mechanisms including:

- In crude units, the conditions that cause large amounts of hydrogen charging into the metal are rarely present.
- Wet H₂S damage almost never occurs in piping because of how piping is made, and because it and its welds, are normally relatively soft (less than Rockwell C 22.)

Chevron's wet H₂S program records have documented cracking attributed to wet H₂S damage; however, this cracking has not resulted in any loss of containment

failures (Wet H₂S Cracking in Chevron Crude Units). The reason for the low risk of pressure containment failure is based on: (1) the generally small crack sizes in crude service and (2) the generally good toughness of pressure vessel and piping materials designed to ASME Section VIII and B31.3.

The Facility reportedly has never experienced wet H₂S cracking in the atmospheric overhead system. However, the crude tower overhead fixed equipment and piping is not post weld heat treated; therefore, based on API-581 guidelines, the overhead equipment theoretically is still at finite risk of experiencing wet H₂S cracking and therefore; appropriately, should be included in their wet H₂S inspection plan. According to Chevron's Risk Management of Wet H₂S Cracking in Process Plants document, it is quite possible for fixed equipment to contain wet H₂S cracks that do not penetrate through the wall. The overhead fixed equipment has been placed in a Category 3 in their Risk Management document (which does not require an internal or external inspection) except for the V-1190 Stabilizer Column Reflux Drum, which has been designated by Chevron as Category 2 conservatively. However, due to the inherent uncertainty in the potential for cracking under post-Modernization Project conditions, Chevron has recommended that an external automatic ultrasonic testing inspection of representative sections of the "wet water" portions of V-1100, V-1160 and V-1190 vessels be conducted as a baseline before the start of post-Modernization conditions, then checked externally again approximately one year after the start of Modernization Project conditions. In addition, they are recommending a one-time internal inspection of the these same vessels during the scheduled maintenance turnaround after the start of Modernization Project operations, using eddy current or other approved internal inspection techniques per the Chevron Wet H₂S program. The Reviewer agrees that this decision to conduct the above inspection is appropriate and should significantly decrease the risk of wet H₂S damage in the overhead equipment.

1.9.2.8.2 Ammonium Bisulfide

Ammonium bisulfide (NH₄HS) forms in an aqueous solution due to the presence of dissolved H₂S and ammonia from a vapor. The maximum amount of ammonium bisulfide that can form is based on stoichiometric conditions. As nitrogen in the crude feed does not convert to ammonia in the charge furnace before going overhead in the atmospheric tower, the only ammonia in the crude unit is ammonia that is injected into the atmospheric tower overhead ahead of the wash water to control corrosion from entrained chlorides and H₂S.

Streams and units handling alkaline sour water (aqueous ammonium bisulfide) are susceptible to aggressive localized corrosion. Below about 250°F, ammonium bisulfide (NH₄HS) can precipitate out of the vapor phase and can cause fouling and plugging. NH₄HS salt deposits can lead to underdeposit corrosion and fouling. If the salts become hydrated, they can be corrosive. Carbon steel is

especially vulnerable to this type of corrosion. 300 Series stainless steels (SS), duplex SS, aluminum alloys, and nickel based alloys have more resistance to the corrosion, depending on the concentration of ammonium bisulfide (NH_4HS) and velocity. NH_4HS is formed from the conversion of nitrogen into ammonia which then reacts with H_2S to form ammonium bisulfide. The critical factors that influence this corrosion include NH_4HS concentration, H_2S partial pressure, velocity and/or localized turbulence, pH, temperature, alloy composition and flow distribution. Corrosion increases with increasing velocity and NH_4HS concentration. A conventional rule of thumb that is widely cited, including in API-571 and API-581, is that ammonium bisulfide concentrations below about 2 wt. % can be safely handled in carbon steel piping and equipment at velocities below about 20 ft./sec. Ammonium bisulfide corrosion in the Chevron Richmond crude unit overhead system is not considered to be a concern under normal operation due to the low amounts of ammonium bisulfide (~0.3 wt. %) calculated to be in the overhead.

Chevron has conservatively estimated the increased post-Modernization Project amount of H_2S in the overhead as greater than a 10% threshold. To conduct post-Modernization Project ammonium bisulfide calculations, they conservatively assumed that the amount of H_2S in the overhead doubled from current conditions. They then used the doubled H_2S quantity to stoichiometrically calculate the amount of ammonia that would combine with the H_2S and then converted that quantity into a wt. % of ammonium bisulfide that would be present in the wash water, assuming that all of the bisulfide would dissolve in the water. Their calculated wt. % of ammonium bisulfide was 0.3 wt. %. This wt. % of ammonium bisulfide is significantly below the amount that industry experience and authoritative published literature states is an amount corrosive to carbon steel (~2 wt. %, based on API-932-B). Therefore, based on a review of Chevron's calculations, the post-Modernization Project increase in H_2S should not impact corrosion rates in the atmospheric tower overhead vs. present conditions. Also, based on their corrosion control/monitoring scheme for the accumulator drum water boot, any increased corrosivity in the overhead water should be able to be detected and mitigation measures taken, if necessary.

1.9.2.8.3 Sour Water Corrosion (Acidic)

As discussed previously, "acidic sour water" is water containing H_2S and with pH below neutral pH (7). As historically, the predominant corrosive species in the crude tower overhead system is alkaline sour water due to the injection of ammonia to neutralize acidic species. Acidic sour water corrosion should not increase post-Modernization Project.

1.9.2.8.4 Ammonium Chlorides

Chlorides were determined not to correlate with higher sulfur or lower API gravity crudes. However, because increased ammonia might be required to

control corrosion post-Modernization Project, ammonium chloride corrosion was considered as a post-Modernization Project damage mechanism.

Higher sulfur in the crude unit overhead systems has the potential to impact the corrosivity of the atmospheric column C-1100 overhead system through sour H₂O corrosion and conceivably through ammonium chloride corrosion. Chlorides can cause corrosion in the crude unit overhead by forming hydrochloric acid ("HCl"), or ammonia/amine chloride salts. HCl is formed in the crude unit by the hydrolysis of salts in the crude that do not get removed in the desalter or converted to harmless sodium chloride by contacting with sodium hydroxide via the caustic injection ahead of the flash drum. The HCl has a high vapor pressure and travels up the atmospheric column into the overhead system as a vapor.

HCl in the vapor phase is not corrosive. It becomes corrosive when water vapor condenses and the HCl dissolves in the water to form hydrochloric acid (HCl). This reaction occurs in the atmospheric and vacuum overhead systems and can also occur in the top of the atmospheric column if the top tray temperature is low enough to permit water condensation.

Chevron uses ammonia in the crude tower overhead to neutralize the HCl along with a water wash to dilute any acidic material to non-corrosive levels. The ammonia can combine with the HCl vapor to form ammonia chloride deposits that can potentially deposit out before the water wash injection point. Chevron controls the potential for chloride salt deposits by ensuring that the process temperatures in the crude unit are well above the salt dewpoint. The Crude Unit Atmospheric Overhead Corrosion Control Best Practice document (Chevron, 2005a) calls for a minimum 25°F margin between the process temperature and the temperature at which the salts form. See Figure A4.13-REL-6 below. Therefore, as long as Chevron's dewpoint calculations are accurate and monitored and they can control the tower top temperatures above the dewpoint, corrosion, fouling and plugging from salt deposits should not occur. Any ammonium chloride salts in the vapor stream will be absorbed into the wash water at the wash water injection point, diluting the hydrochloric acid to non-corrosive, manageable levels. At this point, their pH control system used to maintain a narrow non-corrosive range of pH in the accumulator drum boot water is designed to minimize any corrosive impacts of HCl dissolved in the water.

1.9.2.8.5 High-Temperature (HT) Sulfidation

The below is presented as a logical methodology to review the potential impact of post-Modernization Project is higher sulfur crudes on the crude unit piping and fixed equipment, based on high-temperature sulfidation damage:

1. Identify and document all sulfur-containing piping circuits >450°F using most recent piping and instrumentation diagrams (P&IDs).

02.20.2014 file path: U:\Chevron Renewal\ENVIRON Files\Report\Figures\DEIR Figures\REL

Source: Chevron (T85)

Figure A4.13-REL-6
Chevron Refinery Modernization Project EIR
Chevron Crude Unit Diagram Illustrating Process Monitoring Points

2. Conduct stream simulation analysis to predict the post-Modernization Project sulfur contents of sulfur-containing piping circuits >500°F, based on P90 feed.
3. Estimate pre- and post-Modernization Project corrosion rates using simulation results and recognized HT sulfidation rate corrosion prediction tools such as the McConomy curves, using existing process temperatures and P90 sulfur conditions. Take the difference in pre- and post-Modernization Project corrosion rates to predict any increase in post-Modernization Project corrosion rates.
4. Check identified sulfur-containing piping circuits against the inspection database to verify that previous inspection dates are not overdue.
5. Check post-Modernization Project corrosion rates against existing flags and establish new flags for new conditions, if required.
6. Develop inspection/mitigation/replacement recommendations for all piping with post-Modernization Project predicted thicknesses less than flag thicknesses⁵ before the next scheduled shutdown.
7. Inspect for and identify/locate low Si piping (through locating and inspecting all components to identify any individual components that were corroding at significantly higher rates than the rest of the adjacent piping).

High temperature sulfidation (HTS) is the damage mechanism that caused the August 2012 crude unit fire resulting from failure of the atmospheric tower No. 4 sidecut piping. That piping failed due to uniform thinning at the inner diameter (I.D.) from HTS corrosion and was a low silicon variety of carbon steel, which has been well documented (API-939-C, 2009) as having less resistance to HTS than the higher silicon versions of carbon steel. During the crude unit rebuild, Chevron replaced much of the No. 4 sidecut piping with 9 Cr-1 Mo piping, which should experience acceptably low and manageable corrosion rates (< 10 mpy at ~3.3 sulfur and 670F max.) in the conservative P-90 case used for this analysis. Chevron Richmond currently has carbon steel, 5Cr-1Mo and 9Cr-1Mo equipment and piping in >500°F sulfidation service in the crude unit, but upgrades are planned to replace all but one carbon steel circuit operating at >500°F. The one remaining carbon steel circuit operates at 502°F and exhibits very low corrosion rates.

⁵ Flag Thickness (Tflag): A wall thickness value used for triggering the need for quantitative minimum thickness (Tmin) and half-life assessment. "Flag Thickness" thickness is generally defined as follows:

- Flag Thickness for low pressure pipe 4.5 inches OD and below is 0.100 inches*.
- Flag Thickness for low pressure pipe over 4.5 inches OD is 0.140 inches*. (Upon technical review, it can be reset to 0.100 inches)

Chevron reported that each piping circuit in the crude unit operating under high-temperature sulfidation conditions (>500°F) and per API RP 939-C, Guidelines for Avoiding Sulfidation Corrosion Failures in Oil Refineries, was identified for further analysis. The analysis was done for current operating conditions and for post-modernization operating conditions using the 3.28 wt. % sulfur P90 crude blend case. The analysis results (Chevron, 2014b) detail pre- and post-Modernization Project predicted sulfidation rates, using the McConomy curves, projected new Flag dates based on McConomy curves and actual corrosion rates based on ultrasonic wall thickness measurements. Using the post-Modernization Project sulfur conditions and the McConomy Curves, sulfidation corrosion rates in carbon steel systems were calculated to increase by less than 5 mils (0.005") per year. This spreadsheet was used to evaluate and recommend the 17 piping circuit upgrades to 9Cr material. The spreadsheet analysis results also showed that: (1) many newly calculated Flag dates for carbon steel piping circuits were coming due for additional analysis in the near future and, (2) actual measured corrosion rates in some circuits were high.

Chevron has a best practice for managing sulfidation corrosion, *Inspection Strategies for Preventing Sulfidation Corrosion Failures in Chevron Refineries*, (Chevron, 2009). It is based on the guidelines in API-939-C, *Guidelines for Avoiding Sulfidation (Sulfidic) Corrosion in Oil Refineries* (API-939, 2009), supplemented by Chevron's personal experience with this damage mechanism. Therefore, based on several considerations, including the past sulfidation failure incidents and their sulfidation best practice, which stipulates specification of 9CR piping at sulfidation temperatures greater than 525°F, Chevron is planning on replacing 17 piping circuits currently either carbon steel or 5Cr-1Mo with 9Cr-1Mo at the next scheduled turnaround in 2017, plus four partial circuit replacements (Table A4.13-REL-5 and Table A4.13-REL-6). This Reviewer agrees that this decision is an appropriate one to mitigate risk uncertainty associated with future sulfidation failures.

With the recommended 17 piping circuit upgrades, plus the piping circuits replaced with 9Cr after the fire, that left only one main process circuit of carbon steel (0955-002-013) still remaining as carbon steel, and that piping was new in 2011. This carbon steel line operates at a low sulfidation temperature of 502°F and exhibits very low corrosion rates; therefore, its continued use is justified.

As part of their HTS impact review Chevron also conducted inspections to identify all low silicon piping. This was done by either removing insulation to visually locate pipe butt welds between pipe joints or by using profile radiography to locate individual pipe sections. All carbon steel piping components in crude unit sulfidation service were inspected for remaining wall thickness using their established piping inspection program procedures.

TABLE A4.13-REL-5 COMPLETE PIPING CIRCUITS SCHEDULED FOR UPGRADE TO 9Cr IN 2017

The F-1100 Atmospheric Furnace and the F-1160 Vacuum Furnace present special challenges for assessing risk, based on creep/stress-rupture and sulfidation. Creep/stress-rupture is covered in *Section 1.9.2.8.6* of this Appendix.

Using conservative estimates, the F-1100 and F-1160 furnace tubes could possibly be exposed to post-Modernization Project increased sulfur content feed for as long as two years between January 2016 (the theoretical commencement of Modernization Project operations for purposes of the EIR) and fourth quarter 2017 - the next planned turnaround, when they are scheduled for a smart pig inspection. Therefore, an analysis was done to see if the two furnaces could be

TABLE A4.13-REL-6 PARTIAL PIPING CIRCUITS SCHEDULED FOR UPGRADE TO 9Cr IN 2017

Equipment Number	Equipment Description	Existing Metallurgy	New Material	Replacement Date
0955-015-002	C-1160 OUTLET to E-1165 A/B/C	9Cr/5Cr/ (2) 10" spool piece and drain valves CS	Replace 5Cr and CS with 9Cr; existing 9Cr remains in place.	EOY 2017
0955-015-017	K-1165A/B Pump Out	9Cr/5Cr/CS	Replace short 5Cr deadleg immediately off filters with 9 Cr. CS is either free-draining, isolated, or cool wash oil service, so no need to replace because do not see regular service	EOY 2017
0955-019-034	P-1165/A Case Vents to C-1160	SS/CS	CS is downstream of single SS block valve. Upgrade the 3/4" CS pump case vents with SS to double block and bleed design.	EOY 2017
0955-019-017	Pump Vents	9Cr/5Cr/CS	Replace 5Cr with 9Cr and add a second block valve and bleeder. CS component is downstream of 5Cr single block valve; no project impact on CS portion downstream of the valve.	EOY 2017

operated for that two-year period under post-Modernization Project sulfur conditions safely, based on thinning from sulfidation. Safe operation was defined as remaining tube wall thickness equal to or greater than the Flag thickness of 0.1". For the purposes of the analysis, the P-50 sulfur case (2.38 wt.%) was selected as the most realistic operating scenario. Recent smart pig inspection data was used to determine the existing tube thickness measured at that time and use the P-50 sulfur case and the McConomy curves to calculate predicted P-50 mils per year (mpy) corrosion rates. The analysis results were used to determine starting with the last smart pig inspection date, at what point in time would the tube sample thin to the 0.1" Flag thickness, based on using measured corrosion rates from the smart pig inspection date to 2016 and Modernization

Project high sulfur corrosion rates using the McConomy curves to predict those rates, based on the following formula:

$$[t_y - (Z_{\text{mpy}} \times (2016 - t_y))] - (X_{\text{mpy}} \times 2) \Rightarrow 0.1 \text{ [1]}$$

Where: t_y = min. measured tube thickness in year Y
 Z_{mpy} = historical measured corrosion rate
 X_{mpy} = McConomy C.R. based on P-50 sulfur case and max. TMT
0.1" = Chevron Piping Inspection Guide Flag thickness
2 = 2 year service time from Jan. 2016 to Dec. 2017

The analysis was considered very conservative, in that the thinnest measured wall tube was used and McConomy curve corrosion rates were used, which are documented as being conservative. The available Chevron corrosion rate data also supported the fact that McConomy curve corrosion rates under actual conditions of wt. % sulfur and temperature were much higher than that actually measured. Inspection data provided by Chevron (Chevron [n.d.11]), was the source of the data used for the analysis.

The results of the above analysis showed that:

- Based on a minimum measured wall thickness of 0.193" in 2012 for the F-1100 5Cr radiant tubes, maximum measured tube-metal temperatures (TMT) of 774°F, and existing setting maximum corrosion rates of 5 mpy, the selected F-1100 radiant tube is predicted to reach a 0.1" Flag thickness around October 2017. A full 2-year run is predicted at a sulfur content of 2 wt.%.
- Based on a minimum wall thickness of 0.207" for the carbon steel F-1100 convection section tubes, maximum TMT = 595°F and existing setting corrosion rates of <5 mpy, the convection section tubes should not reach Flag thickness before the 2017 shutdown.
- Based on a similar analysis for the F-1160 furnace, the risk of post-Modernization Project sulfidation damage before the next planned shutdown in 2017 from increased sulfur feeds is considered to be negligible, based on the very low corrosion rates documented in past inspections of the F-1160 furnace tubes (tube wall thicknesses at or above original nominal) and the fact that process and tube-metal temperatures are not expected to increase with post-Modernization Project conditions. Predicted post-Modernization Project corrosion rates under P-50 sulfur feed conditions, using the McConomy curves, while higher than average measured corrosion rates, are still acceptably low with predicted furnace tube Flag thickness above the 0.1" minimum allowable up to the 2017 shutdown where the furnace will be available for inspection.

- Based on the results from the F-1100 radiant tube sulfidation analysis, recommendations for further review after post-Modernization Project operating conditions are initiated are warranted.

1.9.2.8.5.1 Special Case of “Dead Leg” Sulfidation

A sub-category of high-temperature sulfidation that could also increase with increasing sulfur in the crude feed is sulfidation “dead leg” corrosion. Dead leg corrosion occurs when, due to occasional design features, portions of piping are stagnant with fluid still in them for substantial periods of time (typically years). In these dead legs, high-temperature sulfidation may cause gases to evolve and collect, especially at “high points” in the line.

Non-flowing branch lines and dead legs can have higher sulfidation corrosion rates than the primary flowing line because of H_2S evolved from sulfur compounds, which is then trapped at high points and increases the corrosivity of the system. Dead leg sulfidation corrosion is essentially the same basic mechanism as the high-temperature sulfidation discussed above, except that certain specifics of the environment tend to accelerate the sulfidation corrosion, including:

- Elevated temperatures can result in small amounts of corrosive H_2S being formed over time from the less-reactive species.
- The H_2S forms slowly and is slightly soluble in oil, so it is normally swept away by the flowing stream and does not build up.
- Oil in dead legs and non-flowing lines can be heated by heat tracing, thermosiphon from the flowing stream, etc., creating H_2S .
- H_2S can be trapped and build up in high points of dead legs and non-flowing lines, causing accelerated corrosion.

This damage mechanism could affect all systems where sulfidation corrosion could occur from carbon steel up to 9Cr. Chevron has a special “dead leg” sulfidation inspection strategy to monitor and mitigate dead leg sulfidation, recognizing its particular attributes.

Chevron has stated that they have walked down all sulfidation service piping in the units with sulfur streams greater than 500°F, not only in the crude unit, but throughout the refinery and have identified all of their dead legs. The risk of sulfidation corrosion at these locations will be mitigated by identifying and tracking each dead leg per API-570, *Piping Inspection Code, In-service Inspection, Rating, Repair, and Alteration of Piping Systems* (API-570, 2009). The dead legs will also be subject to increased frequency and extent of inspection over historical practices and which go beyond the industry API -574 *Inspection Practices for Piping System Components* (API-574, 2009). Their new dead leg

program is detailed in their Dead Leg Inspection Strategy (Chevron [n.d.5]). A review of their dead leg inspection strategy shows that they understand how to properly identify dead legs and have established inspection procedures adequate to monitor any accelerated corrosion rates in the dead legs.

1.9.2.8.6 Creep/Stress-Rupture

“Creep” is the damage mechanism where a metal subject to stress at high temperatures for long periods of time may slowly elongate and eventually fail. The only crude/vacuum equipment that could be potentially susceptible to creep damage are the F-1100 atmospheric charge furnace tubes and the F-1160 vacuum tower charge furnace tubes. The creep mechanism by itself does not involve corrosion.

Chevron has conducted calculations suggesting that, due to the low stresses in the F-1100 and F-1160 furnace tubes, creep is not a practical threat for the furnace tubes under normal operations, before or part Modernization Project conditions. However, if sulfidation corrosion causes the tubes to thin enough that the internal pressure stresses become high, then creep might increase the risk of failure by creep/sulfidation. Chevron has conducted a detailed analysis of the F-1100 and F-1160 furnace tubes and has concluded that both the convection section and radiant section tubes in F-1100 should be suitable well beyond 2017 during post-Modernization Project operating conditions. However, Chevron's analysis does not include sufficient data as to the present condition of the F-1100 radiant tubes, based on creep damage. Their analysis of the existing condition of the F-1160 furnace tubes is much more conclusive regarding the suitability for continued service under post-Modernization Project conditions. Therefore, based on some degree of unknown risk from failure of the F-1100 radiant tubes from creep/stress-rupture, recommendations to reduce the unknown degree of risk are warranted. The recommendations, as detailed below, involve the testing of selected 5Cr radiant section tubes for laboratory Omega testing to verify their condition based on creep.

1.9.2.9 Crude Unit Recommendations

The operational and feedstock changes contemplated by the Modernization Project have the potential to increase the risks of accidental releases of hazardous substances associated with increasing damage mechanism activity. Specifically, increased sulfur content of feedstocks, increased hydrogen purity produced by the new hydrogen plant, increased H_2S partial pressures in hydroprocessing plants recycle streams, or potentially higher temperatures in the crude unit based on API gravity ratings could all contribute to increased damage mechanism activity post-Modernization Project, thereby warranting the implementation of the following preventive measures:.

1. Based on the results from the F-1100 radiant tube sulfidation analysis, Chevron should monitor the post-Modernization Project sulfur content being fed to the crude unit and use a 2.0 wt.% sulfur content of feed as a trigger to conduct a review of the F-1100 crude charge furnace to study whether the 5Cr radiant tubes are safe to operate until the 2017 shutdown.
2. Chevron's analysis of the atmospheric column furnace F-1100 does not include conclusive evidence as to the present creep/stress-rupture condition of the tubes. Therefore, it is believed that some additional actions are required in order to lower the risk of a creep/stress-rupture or sulfidation failure in a F-1100 tube under post-Modernization Project operating conditions. Acceptable options to lower the risk of heater tube failures include:
 - Furnace F-1100: Option 1, complete all of the following actions:
 - Complete a full internal tube inspection for F-1100 during the 4th quarter 2017 crude unit turnaround using intelligent pigs.
 - Conduct testing on the two currently available, radiant section tubes from the F-1100 Furnace to verify their existing metallurgical, physical and mechanical properties, plus remaining creep life using accelerated Omega creep testing as an input to decide whether the F-1100 furnace should be retubed during the 2017 shutdown.
 - Conduct additional metallurgical, physical, mechanical and, Omega creep testing on radiant furnace tube samples to be removed during the 2017 shutdown, depending on the results of the Omega testing planned for the 2012 furnace tube samples.
 - In 2017, replace tubes as needed in F-1100 per Chevron's replacement criteria for furnace tubes. The replacement criteria are based on the minimum furnace tube thickness on the furnace Safety Instruction Sheet and remaining wall thickness collected by intelligent pig data.
 - Install at least three Permasense® continuous monitoring ultrasonic thickness gauge monitors in each of the furnace outlet systems. If the monitors indicate an increase in corrosion rates greater than 5 mpy, review the need for additional mitigation actions.
 - Furnace F-1100: Option 2:
 - Retube the F-1100A/B furnace during the 2017 turnaround with 9Cr or higher alloy tubes.

3. The vacuum column furnace, F-1160, is constructed of 5Cr radiant tubes. The recommended actions for this furnace are as follows:
 - Complete a full internal tube inspection for F-1160 during the 2017 crude unit turnaround using intelligent pigs.
 - In 2017, replace tubes as needed in F-1160 per Chevron's replacement criteria for furnace tubes. The replacement criteria are based on the minimum furnace tube thickness on the furnace Safety Instruction Sheet and remaining wall thickness collected by intelligent pig data.
4. Conduct laboratory analyses to more accurately determine crude and crude blend sulfur speciation and H_2S evolution, which could be used to predict likely crude corrosion rates. This should be done by end of the fourth quarter of 2015.
5. Develop integrity operating windows (IOWs) for critical crude unit operating parameters per the guidelines in the draft version of API-584. This should be done by end of the third quarter of 2014.
6. The Crude Splitter software is used to predict the distribution of the sulfur in the atmospheric tower sidecut and bottom streams. Verify the Crude Splitter predicted sulfur results with post-Modernization Project data on the sulfur containing streams within the first year of operation following the implementation of the Modernization Project if the trigger points (2.25 wt.% sulfur and 2.75 wt. % sulfur) noted in the Modernization Project Reliability Program are reached.
7. Revise the asset integrity plans for the crude unit atmospheric column reflux drum, V-1100, the stabilizer column reflux drum, V-1190, and the vacuum column overhead seal drum, V-1160, to include inspection for Wet H_2S damage. An external automatic ultrasonic testing inspection of representative sections of the "water wet" portions of V-1100, V-1160 and V-1190 vessels should be conducted as a baseline before the start of post-Modernization Project conditions, then checked externally again approximately one year after the start of the Modernization Project conditions. In addition, a one-time internal inspection should be conducted of these vessels during the scheduled maintenance turnaround after the start of Modernization Project conditions, using eddy current or other approved internal inspection techniques per the Chevron Wet H_2S program.
8. Develop a process monitoring plan for the crude unit overhead to confirm any impacts of the increased sulfur levels. The monitoring plan should be implemented post-Modernization Project and should include:

- Process sampling of the accumulator for pH, chlorides, iron and H₂S content. Compare to established integrity operating windows (IOWs);
 - Monitor desalter pH;
 - Analyze the atmospheric tower post-Modernization Project to quantify if, and how much, increased H₂S is in the overhead system resulting from the increased sulfur feed to the unit;
 - Higher mercaptan crudes could lead to increased sulfidation corrosion rates in the jet or kerosene cuts. Modify asset integrity plans to monitor for potential increased corrosion if higher mercaptan crudes are run compared with current and historical crude and crude blends; and
 - Review the asset integrity plan to ensure that the Permasense continuous ultrasonic monitoring locations are properly placed to ensure early detection, should corrosion rates increase significantly beyond expectations per the McConomy curve predicted rates.
9. The reliability review for the Modernization Project has identified seventeen (17) piping circuits in the crude unit that warrant replacement based on post-Modernization Project operating conditions. The Refinery has committed to accelerating the replacement of these circuits during the next scheduled turnaround for the crude unit, no later than end-of-year (EOY) 2017, as shown above in Table A4.13-REL-5.

The reliability review for the Modernization Project has also identified four partial piping and valve replacements in the crude unit that warrant replacement based on reasonably foreseeable post-Project operating conditions. Chevron has committed to accelerating the replacement of these partial components during the next scheduled turnaround for the crude unit, no later than end-of-year (EOY) 2017, as shown in Table A4.13-REL-6 above.

10. As with all piping circuits in the Facility, new 9Cr circuits should be regularly monitored and inspected. Beginning one year from commencement of Modernization Project operations, the Facility should provide annual reports to the City summarizing the monitoring and inspection results for the identified circuits as noted above. These reports shall, at a minimum, include the following information:
- A list of all piping circuits identified as potentially susceptible to sulfidation corrosion, including specifically, piping circuits identified during the reliability review for the Modernization Project as being susceptible to sulfidation corrosion and subject to potential process changes;

- A list of components identified through the 100% component inspection conducted following the August 6, 2012 fire pursuant to the methodologies set forth in the *API-939-C - Guidelines for Avoiding Sulfidation (Sulfidic) Corrosion Failures in Oil Refineries* and *Updated Inspection Strategies for Preventing Sulfidation Corrosion Failures in Chevron Refineries* (API-939-C, 2009) that may lack sufficient thickness to remain in service until the next scheduled turnaround;
 - A description of the solutions implemented with respect to components of insufficient thickness identified above;
 - A description of the current fixed inspection frequency for carbon steel piping circuits identified as potentially susceptible to sulfidation corrosion;
 - A description of any findings from inspection and monitoring of the piping circuits identified during the reliability review for the Modernization Project as being susceptible to sulfidation corrosion and subject to potential process changes that indicate that any of these circuits lack sufficient thickness to remain in service until the next turnaround and a description of the solution to be implemented with respect to these circuits.
11. Chevron shall obtain all required permits for replacement of these piping circuits pursuant to the California Building Standards Code, inclusive of the California Fire Code, and, once the piping circuits are replaced, shall submit copies of closed permits to the Planning Department to demonstrate compliance with this commitment.
12. Re-evaluate and report on the validity of post-Modernization Project operating and process assumptions made during the reliability review. The reliability review for the Modernization Project assumed that certain operating conditions would exist once the Project is implemented, including projected temperatures, sulfur levels, and corrosion rates for various process units and individual piping circuits. These assumptions were based on either the P50 sulfur case or a conservative 3.28 wt.% (P90) sulfur case. In order to verify that the assumptions made during the reliability review were accurate, the Facility will undertake the following actions:
- When the sulfur weight percent of crude oil processed at the Facility reaches 2.25 wt.% sulfur on an annual average, and then again when it reaches 2.75 wt.% sulfur annual average, the Facility shall:
 - Assemble a reliability review team that will be made up of appropriate subject matter experts (SMEs), including a Senior

Process Engineer, Senior ETC Materials and Corrosion Engineer, Refinery Materials Engineer and Process Operator;

- For all damage mechanisms identified as being affected by the Project, and using then-current inspection and/or monitoring data, the reliability review team shall review, analyze, and, as necessary, update, the data and conclusions prepared during the reliability review for the Modernization Project to determine whether the assumptions made and conclusions reached during the reliability review accurately reflect actual post-Project operating conditions.
- Review any changes associated with sulfur speciation that have resulted from the Project.
- Review any operational or process changes that have occurred post-Project.
- Make recommendations concerning material upgrades and /or enhanced inspection opportunities as necessary based on the re-evaluation.
- Report on the results of this re-evaluation and any resulting recommendations.

13. Installation and Monitoring of Additional Permasense® Monitors on Identified Circuits

Since the beginning of 2013, the Refinery has installed a total of 117 Permasense® probes in the crude unit on six piping systems consisting of carbon steel, 5 Chrome, and 9 Chrome materials. Permasense® is the trade name of a type of high-temperature ultrasonic device that is mounted on a pipe or vessel, and penetrates through insulation. It has wireless sensors that provide periodic equipment thickness readings (at variable intervals, but currently set to collect thickness data twice a day) to monitor a system. Due to noise and sensitivity, the technology is limited to longer-term trending (days and months vs. hours) which is appropriate for piping subject to sulfidation conditions with its predictable rates.

The six piping systems on which the sensors were installed were chosen based on past and anticipated projected future operating conditions. The wireless probes collect pipe wall thickness data while the plant is operating, and are used to monitor corrosion rates. This long-term online monitoring program will be part of the reliability program to ensure safe operation of equipment after the Modernization Project commences operations. Thirteen of these piping circuits with Permasense® monitors installed have been

identified for replacement and will be upgraded to 9 Chrome pursuant to the planned piping circuit upgrades described above, and the Permasense® monitors will not be reinstalled on these circuits. In addition, as part of the Project, the Refinery will install at least 25 additional Permasense® monitors on carbon steel circuits in the SDA unit. These sensors are being installed to confirm the predictive model results that there will be little-to-no sulfidation corrosion in the SDA unit post-Project.

Data from the Permasense® monitors will be utilized in the reporting obligations.

14. Develop and implement physical or administrative controls to assure that carbon steel piping components downstream of high sulfur temperature sulfur streams operating > 500°F are not inadvertently placed into continuous (e.g., placement of a warning tag, locked valve, double-block-and-bleed valves or other measures). This should be completed prior to the commencement of Modernization Project operations.
15. Higher mercaptan crudes could lead to increased sulfidation corrosion rates in the jet or kerosene cuts. Conduct a historical review of purchased crudes and processed crude blends for the 90% confidence level of highest mercaptans processed and use this statistical number to set a review flag in the crude and gas oil acceptance procedure. If higher mercaptans crudes are run at the Facility, review the Permasense® corrosion rate data from this time period as part of the crude management of change lookback. This should be completed prior to the commencement of Modernization Project operations.
16. Add corrosion monitoring locations (CMLs) to the crude unit atmospheric column overhead piping (circuit 0955-003-001) at the termination of the overlay. This should include the termination of cladding in the vertical section of piping as well as the termination point at the inlet to the E-1101's. Review other, similar locations in the crude unit for missing dissimilar metal interface thickness monitoring locations (TMLs). This should be completed prior to the commencement of Modernization Project operations.

1.9.3 Hydroprocessing

1.9.3.1 Process Description

Hydroprocessing refers to the refining process that changes the chemical compositions of hydrocarbons by passing them over a catalyst in the presence of hot, high-pressure hydrogen. The catalyst is contained in one or more reactor vessels, which typically operate at temperatures of 600-850°F and at pressures of several hundred to several thousand pounds per square inch. The objective of hydroprocessing is one or both of the following:

- To remove sulfur and nitrogen compounds (“hydrotreating”)

- To alter the molecular structure of the oil to generate products of greater value (“hydrocracking”)

The feed to the HP units are generally naphtha or gas oils from the crude unit, or purchased feed streams from other refineries. The products coming from the HP units are de-sulfurized or de-nitrified hydrocarbon streams that are fed to other units for further processes, or final products such as gasoline, light gases, etc.

The hydrocarbons in the HP units are not corrosive. Corrosion is the result of non-hydrocarbon components such as sulfur, nitrogen, or chlorides in the system. Sulfur compounds in the feed convert to corrosive H_2S . Nitrogen compounds convert to ammonia, which react with H_2S to form corrosive ammonium bisulfide. Chlorides convert to HCl, which in turn reacts with ammonia to create ammonium chloride. Finally, at high enough temperatures and pressures hydrogen is capable of damaging metals.

The major parts of a hydroprocessing unit are:

- Unit feed and preheat system which raises the feed temperature and pressure. This includes piping and feed/effluent heat exchangers. Hydrogen is also introduced in this portion of the plant. The hydrogen enters at relatively cool temperatures such that alloy steels are not needed to combat sulfidation or high-temperature hydrogen attack.
- Feed furnaces are all 300-series stainless steels selected to avoid both sulfidation and HTHA, with typically 347SS used to minimize risk of polythionic SCC.
- The reactor loop uses 300-series stainless steels as cladding material for the reactors, and solid 300SS piping. The process exiting the reactors is used for preheat to the feed using the feed/effluent exchangers, then travels on to downstream separation vessels.

The reactor contains catalyst(s) and typically operates high pressures and temperatures. Hydrogen is injected into the feed which is heated in feed/effluent exchangers and a furnace. In the reactor(s), sulfur and nitrogen compounds are converted to H_2S and ammonia. The reactor effluent is cooled through various heat exchangers and typically one or more air coolers, and then is sent to the separator vessels. Water is typically injected for fouling/corrosion control upstream of the air coolers. The gas phase from the separators consists primarily of hydrogen with some very light hydrocarbons and a high percentage of the H_2S generated in the reactors. Gas from the separator is recycled back to the feed through a compressor, with some make-up hydrogen also being added. The liquid hydrocarbon phase from the separators is sent through pressure let-down valves to the fractionation section of the unit. The water phase from the separators contains almost all of the ammonia formed in the reactors. The

dissolved H_2S in this water combines with the NH_3 to form ammonium bisulfide (NH_4HS), as well as inorganic salts such as ammonium chloride. Traces of cyanide may also be present, depending on the feed to the unit.

As the process continues to the products section it is cooled further, and the gases (hydrogen, light gases) are separated from the liquids (hydrocarbons, water). Towards the end of this section large air coolers are used; this portion of the process is typically termed the Reactor Effluent Air Cooler (REAC) section. The corrosiveness of the REAC systems vary widely, depending upon the amount of the contaminants and the process, which in turn necessitates varying degrees of alloying in this section of the plant. Water wash systems are used for removing the corrosives from the reactor effluent stream. Chevron documents their process control, alloy and water wash strategies to control REAC ammonium bisulfide corrosion in the HP-002 "Reactor Effluent Air Cooler Piping and Equipment Corrosion Control Guidelines" Best Practice (Chevron [n.d.3]).

Downstream of the separators the hydrocarbon goes to the hydroprocessing distillation section which is primarily carbon steel, except for the distillation furnace tubes, which have shown erratic sulfidation behavior in the industry.

The Chevron refinery has eleven HP units, as detailed in Table A4.13-REL-7 below. These units have various degrees of damage mechanism susceptibility, based on post-Modernization Project conditions.

Of the eleven HP units, four of the units will see no impact of increased sulfur in feedstock:

- Chevron states that the GHT will not see an increase in feed sulfur because the sulfur content of the fluid catalytic cracker gasoline, which feeds the GHT, will not change.
- Chevron states that the ISO, LNF and HNF units will not see an increase in feed sulfur as they are all 2nd-stage units. These second stage units process the product from the 1st-stage TKN, LNC, and HNC units. While these three 1st-stage units will see a higher sulfur feedstock, they must still desulfurize and denitrify to the same level as current specifications to protect the 2nd-stage catalyst. Therefore, the 2nd-stage units (ISO, LNF, and HNF) will not see higher sulfur levels.

The TKN, LNC, and HNC units will see higher feed sulfur (Chevron [n.d.7]). In addition, the JHT, DHT, and TKC units will also see an increase in feed sulfur levels. However, the reactor inlet and outlet piping, which see process temperatures above the threshold sulfidation temperature ($\sim 450\text{-}500^\circ\text{F}$), are 300-series stainless steel to mitigate the high-temperature sulfidation corrosion so that there is no significant increase in corrosion risk in this area of the unit resulting from the higher sulfur feed. The NHT will also see a modest increase in sulfur but it does not have any carbon steel in the plant operating above 450°F ; it

TABLE A4.13-REL-7 CHEVRON RICHMOND HYDROPROCESSING UNITS

Unit	Description	Feed Source	Modernization Project
GHT	Fluid Catalytic Cracker Gasoline Hydrotreater	Fluid Catalytic Cracker Unit	Note 1
NHT	Naphtha Hydrotreater	Crude Unit Stabilizer	Note 2
JHT	Jet Hydrotreater	Crude Unit #1 & #2 Sidecut	Note 2
DHT	Diesel Hydrotreater	Crude Unit #3 Sidecut	Note 2
TKC	Fluid Catalytic Cracker Feed Hydrotreater	SDA unit DAO, Imports	Note 2
TKN	Stage I Denitrification	Crude Unit #4 & #6 Sidecut, Imports	Note 3
ISO	Stage 2 Isocracker	TKN	Note 1
LNC	Light Neutral Hydrocracker	Crude Unit #7 Sidecut	Note 2
LNF	Light Neutral Finisher	LNC	Note 1
HNC	Heavy Neutral Hydrocracker	Crude Unit #8 Sidecut	Note 2
HNF	Heavy Neutral Finisher	HNC	Note 1

Note: 1 – No Changes

2 – Sulfur increase in the P-50/P-90 Case and Sulfur and Nitrogen increases in the Sensitivity analysis

3 – Sulfur and Nitrogen increases in the P-50/P-90 Case and Sulfur and Nitrogen increases in the Sensitivity analysis

has 1 ¼ Cr- ½ Mo chrome piping in the reactor inlet and outlet piping, but it is all operating below 550F, which per the McConomy Curve is equivalent to less than a 3 mpy corrosion rate.

1.9.3.2 Corrosion and Materials Selection in Hydroprocessing Units ⁶

1.9.3.2.1 Reactor Loop— General

The materials of construction used in the reactor loop of a hydrotreater must be resistant to the following forms of corrosion damage:

- High-temperature hydrogen attack.
- High-temperature H₂-H₂S corrosion.
- Aqueous corrosion by ammonium bisulfide

⁶ C.A. Shargay, A.J. Bagdasarian, J.W. Coombs, W.K. Jenkins, Corrosion in Hydroprocessing Units, NACE International, Houston, TX.

- Stress corrosion cracking by chlorides, sulfur acids, or sulfides.
- Naphthenic acid corrosion (if feed has a high neutralization (TAN) number).

1.9.3.2.2 Reactor Feed System

Up to the point of recycle hydrogen addition, the hydrocarbon feed to the plant is generally noncorrosive to carbon steel, except when the feed contains H_2S at $>500^\circ F$ or naphthenic acids at $>450^\circ F$. In those cases where the plant feed is corrosive because of high temperature and dissolved H_2S , corrosion can be minimized by using the appropriate alloys to resist high-temperature sulfidation.

After the point of recycle hydrogen addition, progressively higher alloys are required to resist both hydrogen attack and high-temperature H_2 - H_2S corrosion as the feed is heated. The threshold temperature for H_2 - H_2S corrosion depends on the amount of H_2 introduced with the recycled gas, but in most plants it is on the order of $\sim 500^\circ F$. Above this temperature, austenitic stainless steels are typically used for piping and exchangers to provide corrosion resistance. Exchanger bundles are typically Type 321SS, and the shells and channel sections are clad with Type 321SS or Type 347SS. However, Type 347SS is normally used for cladding on thick-walled components, as there is a risk that Type 321SS might sensitize during the lengthy fabrication heat treatment.

Hydrogen attack becomes a materials consideration in the reactor feed system when above about $450^\circ F$. Although stainless steels are immune to hydrogen attack under plant conditions, hydrogen can diffuse through stainless cladding to attack the base metal. Based on these considerations, the reactor feed system is normally carbon steel where temperatures are below about $450^\circ F$. Within a relatively narrow temperature span of $450^\circ F$ to 500 - $550^\circ F$, 1 1/4Cr-1/2Mo or 2 1/4Cr-1 Mo may be used where resistance to hydrogen attack is required. Above $500^\circ F$ to $550^\circ F$, piping will generally be Type 321SS steel to prevent H_2 - H_2S corrosion and exchanger channel sections and shells will be stainless clad, with 1 1/4Cr-1/2Mo or 2 1/4Cr-1 Mo base metal used as needed for protection from hydrogen attack.

1.9.3.2.3 Reactor Feed Furnaces

Tubes and return bends are commonly constructed of Type 347 SS, although Type 321SS has also been used. Return bends should be wrought rather than cast, both to obtain superior quality and because castings tend to develop sigma embrittlement above $1000^\circ F$.

1.9.3.2.4 Reactors

Reactors are constructed of low alloy steel for hydrogen attack reasons and are protected against H_2 - H_2S corrosion by austenitic SS roll-bond cladding or weld overlays. The most common base metal for reactors is 2 1/4Cr-1Mo steel, although 3Cr-1Mo has also been used. Alloys lower than 2 1/4Cr-1Mo are

occasionally used when temperature and hydrogen partial pressure permit. Reactor internals are constructed of an austenitic stainless steel, typically Type 321SS or 347SS. Aluminizing is sometimes specified for catalyst support screens to help prevent corrosion which could result in plugging from scales. Aluminum is essentially immune to H_2S corrosion.

1.9.3.2.5 Reactor Effluent System

In the reactor effluent system, from reactor to the reactor effluent/stripper feed exchanger, materials selection is based on the same criteria as in the reactor feed system. Stainless steels should be used for corrosion protection until the stream is cooled below the threshold for high-temperature H_2 - H_2S corrosion (about 500°F). Alloys resistant to hydrogen attack should be used down to about 450°F. From the reactor outlet temperature down to about 500°F, piping and exchanger bundles are generally Type 321SS, and exchanger shells are Type 321SS or Type 347SS clad. Base metals used for exchanger shells may again be 2 1/4 Cr-1 Mo or 1 1/4 Cr-1/2Mo, depending on the alloy content required to provide resistance to hydrogen attack. Below the 450°F hydrogen attack threshold, carbon steel is generally used.

1.9.3.2.6 Reactor Effluent—Distillation Feed Exchangers

Many plants use an exchanger that cools the reactor effluent stream by exchanging it with the separator liquid on its way to the first distillation column after the reactor system. Such exchangers pose special corrosion problems. One problem is entrainment of small quantities of salt-containing water in the separator liquid. As this stock is heated, this water evaporates, leaving salt deposits on the tubes. Carbon steel tubes may corrode in the presence of these deposits. Tube life is highly variable, depending primarily on temperature and the amount of salt entrained into the exchanger. Chrome-moly steels perform no better than carbon steel in this instance. Austenitic stainless steels are likely to fail by chloride stress corrosion cracking or underdeposit, ammonium chloride pitting. In general, austenitic stainless steel tubes should not be used in this service except in existing plants where good performance has been proven. This results in the materials selection for these tubes being a choice between carbon steel and expensive alloys such as Alloy 825, AL6XN or Alloy 625. For new plant construction, carbon steel is generally specified. The exception is when reactor effluent-side temperatures are so high that a more resistant alloy is required for high-temperature H_2S corrosion. Under these conditions, and for replacement of existing exchanger bundles where carbon steel shows inadequate life, an alloy with good resistance to chloride corrosion and sec should be used.

1.9.3.2.7 Effluent Air Coolers

Effluent air coolers are probably the equipment most vulnerable to ammonium bisulfide corrosion. Most plants initially install carbon steel tubes for effluent air coolers, however some have installed duplex stainless steel or Alloy 800 or 825.

In some cases, carbon steel has experienced corrosion failures due to excessive velocities, oxygen in the injection water, maldistribution of flow or other causes. Where such problems have occurred and tube materials have been upgraded, Monel 400, Alloy 800 or 825 has been used for tube replacement. The Alloy 800 series provides resistance to high concentrations of ammonium bisulfide. However, there have been cases of polythionic SCC of Alloy 800 piping and equipment. Alloy 825 is stabilized and contains molybdenum, and hence, has superior resistance to polythionic and chloride SCC, as well as NH_4HS corrosion. Duplex stainless steels such as Type 2205 are increasing in use for tubes and header boxes. Although they should have good NH_4HS corrosion resistance, austenitic stainless steel tubes have seldom been used in this service, due to the risk of chloride stress corrosion cracking. In the past, several companies have used Type 410SS or Type 430SS tubes in effluent air coolers but failures have occurred by isolated pitting. Alloy 400 (Monel) has been used successfully for a few air coolers in the past, but may not be suitable for units with high levels of NH_4HS . In some plants, effluent air coolers have been constructed with stainless steel ferrules at both inlet and outlet ends of the steel tubes. This provides increased protection against tube end erosion-corrosion. Ferrules have also been installed with good results in existing steel air coolers where tube end attack had occurred. When ferrules are used, the ends of the ferrules must be tapered to provide a smooth flow transition. Carbon steel header boxes may also experience corrosion if velocities or turbulence are excessive. Industry experience indicates that the majority of those effluent air coolers experiencing tube corrosion will also suffer attack on header boxes. For this reason, alloy header boxes should be used with alloy tubes. Although ammonium bisulfide corrosion is the major concern, failures can also occur from NH_4Cl corrosion. NH_4Cl condenses at temperatures above the NH_4HS condensation temperature. The deposits are hygroscopic and often provide enough cooling of the metal to result in water condensation and acid formation beneath the deposit. No practical materials upgrade will resist this problem, so it is usually avoided by raising the process temperature.

1.9.3.2.8 Effluent Air Cooler Inlet and Outlet Piping

The piping upstream (from the water injection point) and downstream of the effluent air cooler is often subject to the same NH_4HS erosion-corrosion problem as the air cooler. Corrosion is typified by highly localized metal loss at bends, tees, and other points of local turbulence. Such corrosion is most likely to occur when the process fluid is high in NH_4HS concentration, and where fluid velocities are high. Carbon steel piping should be designed with a 20 ft./s maximum limit. When new units are predicted to be extremely corrosive, when high reliability is desired, when periodic rigorous inspection is considered difficult or uneconomical, or when corrosion occurs in existing plants, alloy piping is often installed. Alloy 800, Alloy 825, Type 316L SS (for application below 140°F), Alloy 20 and duplex alloy 2205 have been used. The upper velocity limit for alloy

piping can be increased to approximately 30 ft./s. When carbon steel is used, it generally has a high corrosion allowance of 1/4 in. Balanced inlet and outlet piping is also typically specified. This type of corrosion can also occur downstream of the separators in lines handling wet hydrocarbons or foul water, and in other piping where the process fluid contains appreciable quantities of H_2S and ammonia, and any quantity of liquid water.

1.9.3.2.9 Separator Vessels

Except for units operating with greater than 10% NH_4HS , separator vessels normally have very low corrosion rates. The major concern is that the incoming process fluid may impinge on the shell or heads, causing localized NH_4HS corrosion at that point. Typically, installing a stainless steel impingement baffle or wear plate of adequate size to shield the entire impingement area avoids the problem. The only major exception is the hot separator in a hydrotreater design where the first separator operates at or near the full reactor outlet temperature. Accordingly, stainless-clad construction is used to provide resistance to high-temperature H_2-H_2S corrosion. The base metal is chosen to resist hydrogen attack at operating temperature. Cold separators containing sour water may be subject to severe HIC and SOHIC. On recent units, these vessels have been built of HIC resistant steel or entirely clad with a 300 series stainless steel.

1.9.3.2.10 Recycle Hydrogen System

Significant corrosion is seldom encountered in this part of the system. The only potentially serious materials problem is SSC of the recycle gas compressor, as it typically contains materials like 4330 or 4140 steel, which can be susceptible to SSC if too high in hardness. To avoid this problem, it is common practice to limit the strength and hardness of compressor materials.

1.9.3.2.11 Distillation Section

Construction materials used in the distillation section are chosen on the basis of the need to resist high-temperature H_2S corrosion. Where H_2S is present at temperatures above about 500°F (depending on H_2S concentration), alloy is required. Where H_2S is absent or where temperatures are below 500°F, carbon steel is generally adequate. Where the temperature exceeds 600°F, corrosion may occur at H_2S levels as low as 1 ppm. Aside from the possibility of high-temperature H_2S corrosion, the only other corrosion concern is in the overhead of the distillation column. Overhead condensers and drums exposed to both water and H_2S may experience moderate corrosion, but this is rarely a serious problem and may be further controlled by injection of a filming amine inhibitor. In the overhead systems, many refiners may apply materials and fabrication controls to minimize wet H_2S cracking; however, HIC steels are not typically used in this location.

1.9.3.3 Hydroprocessing Damage Mechanisms

Based on the reported feeds to the seven impacted units, the following damage mechanisms were to be potentially impacted, based on post-Modernization Project conditions: (1) high-temperature sulfidation; (2) H_2 - H_2S Corrosion; (3) ammonium bisulfide corrosion; (4) wet H_2S damage and (5) HTHA. The damage mechanisms ammonium chloride, creep/stress rupture, PTASCC, temper embrittlement and, chloride SCC were determined to not change from existing conditions due to reasons discussed previously in *Section 1.7, Damage Mechanisms Active in the Facility and Impacted by the Modernization Project's Operational and Feedstock Changes* and *Section 1.8, Damage Mechanisms potentially Active in the facility impacted units but Determined to be not affected by the Modernization Project* of this Appendix.

1.9.3.3.1 High-Temperature Sulfidation and H_2 - H_2S Corrosion

HP units typically have two versions of high-temperature sulfidation corrosion possible:

1. High-temperature sulfidation corrosion in which significant hydrogen is not involved (essentially the same as described in the crude unit). This is often referred to as H_2S corrosion.
2. High-temperature sulfidation corrosion in which significant hydrogen is involved. This is often referred to as H_2 - H_2S corrosion.

In the Chevron HP units the hydrogen is either introduced into carbon steel or low alloy piping early in the process where the temperatures are still relatively low (~400°F), below sulfidation damage and HTHA initiation temperatures, or is injected into 300 series SS. Therefore, the HP units are exposed to the H_2 - H_2S version of the corrosion until the hydrogen is removed near the end of the process. Therefore, based on the conservative use of 300-series stainless steel piping and equipment in H_2 - H_2S service above ~450°F the Modernization Project will have no reasonably foreseeable impact related to high-temperature sulfidation.

At the distillation (fractionation) section of the hydroprocessing plants located at the back end of the HP units, much of the hydrogen and H_2S has been removed but the process stream is still sour. The industry has found that the corrosion behavior in the distillation section of HP units industry wide has been erratic (API-939-C, 2009) and this hydroprocessing distillation section corrosion issue is under continuing study in the industry. Therefore, Chevron needs to remain vigilant for possible corrosion in the distillation sections of the plants.

1.9.3.3.2 Ammonium Bisulfide Corrosion

As discussed in other sections of this Appendix, ammonium bisulfide forms from the chemical combination of H_2S and ammonia, typically in aqueous solutions where the two species are contacted with liquid water or by direct condensation from a vapor phase if solubility limits are exceeded. The ammonia and H_2S are created in the reactor section of HP units from catalytic conversion of sulfur and nitrogen in the feed to the unit.

The industry best practice document for ammonium bisulfide corrosion in hydroprocessing plants is API-932-B, *Design, Materials, Fabrication, Operation, and Inspection Guidelines for Corrosion Control in Hydroprocessing REAC Systems* (API-932-B, 2012). API-932-B does not provide specific guidance on inspection frequencies but general guidance on variables affecting corrosion rates and materials selection criteria. Chevron also has developed their own proprietary hydroprocessing Best Practice Document, HP-002 -*REAC Piping and Equipment Corrosion Control Guidelines* (Chevron [n.d.3]), that incorporate elements of API -932-B but add Chevron specific guidelines to provide guidance for acceptable operating conditions, based on plant metallurgy with regards to ammonium bisulfide corrosion.

Ammonium bisulfide corrosion in reactor effluent streams is influenced by three parameters: (1) H_2S partial pressure; (2) ammonium bisulfide concentration; and (3) velocity (shear stress). Chevron's HP-002 guideline defines operating severity ranges for ammonium bisulfide corrosion where each severity range has specified material selection, process limits, and inspection requirements. Chevron has a refinery REAC Corrosion Control Project underway which is planned for completion prior to the Modernization Project. This upgrade project was initiated to address changes made to HP-002 in 2011, which was revised to include the influence of H_2S partial pressure on ammonium bisulfide corrosion rates. Until certain metallurgy upgrades are made to TKN and Sour Water System the refinery crude blend has been limited to keep operations within the new HP-002 guidelines (Chevron [n.d.9]).

As mentioned above, Chevron has its own proprietary Best Practice document (HP-002) for controlling ammonium bisulfide corrosion. They calculate H_2S partial pressure in the reactor effluent using a proprietary refinery sour gas system simulation model. This model predicts the H_2S concentration in the High Pressure Separator. Multiplying the calculated H_2S concentration times the operating pressure yields an H_2S partial pressure. The ammonium bisulfide (NH_4HS) concentration in wash water is based on the degree of nitrogen conversion to ammonia that the reactor system will accomplish. The calculated ammonia in the reactor effluent vapor is removed by a water wash where it combines stoichiometrically with H_2S to generate ammonia bisulfide. These two parameters (H_2S partial pressure and ammonium bisulfide concentration) along with velocity

define the operating regime severity of the reactor effluent system according to a set of internal guidelines specified in HP-002.

HP-002 Best Practice specifies design, materials and process parameters such that if the plant(s) stay within the parameters, corrosion remains low (less than 10 mpy carbon steel, 5 mpy REAC air cooler tubes, 5 mpy alloy piping, 3 mpy alloy REAC tubes). HP-002 also prescribes equipment inspection monitoring and process monitoring and control that take into account unit specific metallurgies and design that are used to verify HP-002 predicted corrosion rates. An important process parameter in controlling NH_4HS corrosion is the use of a water wash to absorb the NH_4HS from the overhead vapor stream. The use of the water wash permits the control of maximum NH_4HS content in the sour water within practical limits regardless of the amount of NH_3 being formed in the reactor. Therefore, because of the water wash, the absolute values of nitrogen in the feed to the HP unit become less important. See the below figures A4.13-REL-7 to A4.13-REL-11 for calculated pre- and post-Modernization Project corrosion rates for the HP high severity units, including the high sensitivity nitrogen case.

As an example of how the data points were derived, Table A4.13-REL-8 below gives feed property assumptions and resulting ammonium bisulfide and hydrogen sulfide partial pressures for the post-Modernization Project high nitrogen case shown by the yellow dots in the graphs.

TABLE A4.13-REL-8 HIGH SEVERITY HYDROPROCESSING UNIT P50 SULFUR AND NITROGEN FEED CASES VS. THE HIGH NITROGEN SENSITIVITY CASE

NH ₄ HS and H ₂ S PP Summary				
Crude Case:	1877 ppm N			
Crude Sulfur, wt.%	2.36			
Feed Property				
	Sul, wt.%	N, PPM	NH ₄ HS, wt.%	H ₂ SPP, psia
TKN	2.1	984	9.20	127
LNC	3	1308	8.20	102
HNC	3.2	1930	11.70	143
TKC	3.2	2304	14.9	92

The analysis included foreseeable nitrogen levels, including those under the more probable P-50 sulfur case and the improbable P-90 sulfur case, which includes a nitrogen range of 1138 ppm to 1541 ppm. Additionally, because the analysis in *Appendix 4.3-MET* concludes that “it is likely that the crude oils processed by the Refinery if the Modernization Project is implemented have the

potential to contain additional nitrogen,” a sensitivity analysis was completed that evaluated nitrogen levels at much higher levels (up to 1877, or 22% higher than the high nitrogen case of 1541 ppm). The sensitivity analysis case is shown in yellow in the curves above. The graphs show that, under all projected increased nitrogen feed rates to the HP units, corrosion rates remain below HP-002 guidelines.

1.9.3.3.3 Wet H₂S Damage

Similar to the assessment of the crude and SDA units, the likelihood of wet H₂S damage is not expected to change as the wet H₂S equipment and piping are already presently in National Association of Corrosion Engineers (NACE) MR0175/ISO15156 sour service. Any increase in wet H₂S above sour limits would not significantly impact the damage mechanism. Regardless, the wet H₂S sections of the HP units are already being inspected for wet H₂S per Chevron’s wet H₂S best practice.

1.9.3.3.4 HTHA Attack

The hydrogen feed to the HP units will increase from about 95% to 99% purity with installation of the new hydrogen plant. This purity increase amounts to an approximately 4% increase in the hydrogen partial pressure. HTHA attack of carbon and low alloy steels is based on the hydrogen pressure and temperature, per the “Nelson Curves” in API-941 *Steels for Hydrogen Service at Elevated Temperatures and Pressures in Petroleum Refineries and Petrochemical Plants*. This increase is insignificant with respect to increasing the potential for HTHA by going over the limits of a API-941 resistance curve for a specific alloy (API-941, 2008). In addition, Chevron has stated that they have a 50°F and 50 psig buffer limit for materials subject to HTHA in the HTHA Best Practice, except for 2 1/4 Cr to 1/2 Mo which has a 25°F and 50 psia buffer limit. This 25/25 buffer zone is common in the industry. The only unit where low alloy steels are installed where hydrogen is injected is the NHT unit and the 1.25Cr-1Mo piping installed in this unit operates at temperatures (550°F) well below the temperature for HTHA of this material.

1.9.3.4 Hydroprocessing Recommendations

1. At the 2.25% wt. % sulfur in crude feed trigger point, evaluate and modify as warranted, based on any increased sulfur in this section of the unit, inspection plans (what, where and how often) for the distillation section of the HP units where sulfidation corrosion rates have been “erratic” and uncertain, per API-939-C.
2. Report on the progress of the project to compare the HP-002 Best Practice Guideline regarding, water wash, to API-932-B recommendations to ensure that the HP-002 document is consistent with 932-B guidelines. This report

should be submitted prior to the commencement of Modernization Project operations.

3. Conduct process monitoring and sampling for post-Modernization Project operations for all HP units, to develop process data to confirm assumptions made during the damage mechanism review regarding amounts of H_2S and ammonium bisulfide in the overhead systems. This shall be completed after commencement of Modernization Project operations.
4. Develop integrity operating windows (IOWs) for the HP units to incorporate existing critical reliability variables such as the wash water rate for NH_4HS corrosion control. The IOWs shall be established prior to the startup of Modernization Project operations.
5. If the REAC Corrosion Control Project (TKN) is not completed pre-Modernization Project, conduct a review of current operations to ensure that corrosion rates will remain under REAC best practice guidelines with any increase in sulfur to the unit. This shall be completed prior to the startup of Modernization Project operations.

1.9.4 SDA Unit Reliability Impacts and Recommendations

1.9.4.1 Process Description

The SDA unit was upgraded and redesigned by mid-1994 to process 50,000 BPSD of residuum oil using Kerr-McGee Corporation's ROSE® technology. These facilities are designed with some flexibility to extract deasphalted oil (DAO) product from vacuum resid using a mix of solvents. 39,000 BPSD of DAO is extracted from 50,000 BPSD of vacuum resid (charge) with a C5-rich solvent. The remaining asphalt by-product is produced at a rate of 11,000 BPSD. DAO product is processed in the downstream TKC (high pressure hydrocracker) unit and subsequently in the Facility's fluid catalytic cracker unit to produce valuable lighter products. The asphalt by-product is cut with light cycle oil (LCO) in the unit to produce tar. The tar is blended in downstream operations to produce heavy fuel oil. The SDA unit can be divided into the following functional segments: separator section, DAO stripping section, asphaltene stripping section, solvent circulation systems, and hot oil system.

Based on a review of the SDA process description and process flow diagrams, the SDA unit will process resid from the crude unit vacuum column. Table A4.13-REL-9 shows the potential changes in post-Modernization Project sulfur conditions in the unit:

TABLE A4.13-REL-9 SDA SULFUR LEVELS

	Benchmark (P50)	P90	Baseline¹
SDA Feed	5.7%	6.9%	3.8%
DAO	5%	6.2%	3.6%
Asphalt	7.5%	8.7%	4.7%
F-1 100/200 to C-102/122	4.9%	5.7%	2.9%

Note: ¹Baseline is based on data from January through July 2012.

Based on the above projected changes in the vacuum resid feed to the SDA unit, the post-Modernization Project damage mechanisms are considered to be a subset of those identified for the crude unit, based on increased sulfur contents and otherwise similar operating conditions, i.e., high-temperature sulfidation and wet H₂S damage (SSC/HIC/SOHIC), based on increased H₂S in the overheads of the SDA unit.

The majority of the SDA unit is constructed of carbon steel, except for the feed heater furnace (chrome alloys) and some hotter heat exchanger tubes (chrome alloys).

1.9.4.2 Damage Mechanisms Assessment of Chevron Richmond Refinery's SDA Unit

1.9.4.2.1 HT Sulfidation

Based on an expected high-temperature sulfidation damage mechanism, the damage mechanism review process would be expected to be the same or similar to that for the similar service crude unit piping and equipment, i.e., (1) identify sulfur piping circuits above 500°F; (2) inspect for and identify/locate low Si piping (through locating and inspecting all components to identify any individual components that were corroding at significantly higher rates than the rest of the adjacent piping); (3) calculate (or simulate) the post-Modernization Project sulfur contents of the existing sulfur containing piping circuits; (4) calculate new corrosion rates and flag dates based on the higher sulfur content using the McConomy curves; (5) compare the post-Modernization Project corrosion rates and new flag dates with the existing piping circuit inspection database; and (6) develop a mitigation/monitoring plan for any piping circuits/fixed equipment that are projected to reach their flag dates prior to the next scheduled shutdown.

All piping/equipment in the SDA unit is carbon steel including that operating above the sulfidation temperature threshold of greater than about 500°F, except for the F-100/F-120 furnaces, in which the furnace tubing is either 7Cr or 5Cr

low alloy steel. Chevron has conducted a sulfidation inspection of the SDA unit, including conducting a 100% component inspection for low silicon carbon steel piping operating above 500°F and inspection for sulfidation “dead legs” per their sulfidation dead leg procedure. The facility plans to inspect all carbon steel piping operating between 450°F and 500°F by the end of 2014. In addition to their existing CMLs, additional CMLs were placed on all carbon steel piping where corrosion rates showed a deviation from adjacent piping. Re-inspection intervals for the newly placed CMLs were shortened based on the measured thicknesses and corrosion rates, per API-570 guidelines. The furnace tubes were inspected in 2009 using smart pig technology.

A review of Chevron’s summary inspection results and independent verification of corrosion rates using the McConomy curves, based on their published process temperatures and the sulfur levels (Chevron, 2014e), showed projected increases in high-temperature sulfidation corrosion rates to be minimal or about 5 mpy above current sulfur content rates. An analysis of existing available corrosion rate data for existing CS piping/equipment operating above 500°F show all corrosion rates less than 10 mpy. The flag dates for the piping systems are well into the future (the nearest SDA flag date is 2026). However, recognizing that corrosion rates will probably increase with increasing post-Modernization Project sulfur content of crude feed, a baseline inspection based upon the sulfur level triggers discussed above is recommended. In addition, Chevron has committed to installing 25 Permasense® probes in the SDA unit high-temperature carbon steel piping. Therefore based upon the existing good condition of the sulfidation piping/equipment and current low corrosion rates combined with the post-Modernization Project monitoring to be implemented, the continued use of carbon steel piping and equipment is justified.

1.9.4.2.2 Wet H₂S Damage

Based on the increased sulfur-containing resid to the SDA unit the H₂S content of the overhead streams in several equipment items is expected to increase. Vessels potentially impacted include V-141, Low Pressure Solvent Accumulator, V-142, Asphalt Flash Solvent Accumulator and the V-143/144 High Pressure Solvent Accumulators. There has been no data presented to verify to what extent the H₂S in these overhead systems will increase over current conditions; however, it would be prudent to verify post-Modernization Project worst case conditions regarding H₂S in the SDA overheads and target one or more of the accumulator drums for an internal inspection using Chevron’s existing wet H₂S program guidelines.

1.9.4.3 SDA Recommendations

1. Verify post-Modernization Project conditions regarding H₂S content in the SDA overheads and target one or more “water wet” vessels for inspection using internal eddy current, external automatic ultrasonics (AUT) or other

non-destructive evaluation (NDE) techniques appropriate for wet H₂S cracking detection within one year of operation under post-Modernization Project conditions.

2. Conduct water boot analysis for corrosive constituents similar to that conducted in the crude unit on the unit overhead accumulator drums, including cyanides. This should be conducted at the 2.25 wt.% and 2.75 wt. % sulfur trigger points.
3. When the sulfur wt.% of crude oil processed at the Facility reaches 2.25 wt.% sulfur on an annual average, and the again when it reaches 2.75 wt.% sulfur annual average, the Facility shall trigger the same responses for the SDA plant as described in the recommendation section of the crude unit.
4. Conduct a follow-up smart pig inspection of F-100 and F-120 furnace tubes during the first planned maintenance after the unit has seen at least 1 year of post-Modernization Project operating conditions.
5. Install at least 25 additional Permasense® monitors in carbon steel circuits in the SDA including sulfidation “dead legs,” based on a critical review of historical corrosion rates. These sensors will confirm the predictive model results that there will be little-to-no increase in sulfidation corrosion in the SDA post-Modernization Project. These installations should be completed prior to the commencement of Modernization Project operations.
6. Develop IOWs per draft API-584 for identified damage mechanisms in the SDA unit. The IOWs should be established prior to the commencement of Modernization Project operations.
7. Develop process monitoring and sampling plans for post-Modernization Project operating conditions to confirm assumptions made during the damage mechanism review project. The monitoring and sampling plans should be developed prior to the commencement of Modernization Project operations, and should be implemented after commencement of Project operations following an increase in sulfur content to the SDA unit.

1.9.5 Amine Systems

1.9.5.1 Process Description

The new amine system function removes the H₂S from the TKC sour recycle gas streams. The major components are the DEA absorber, C-430, the rich DEA flash drum V-2415, the DEA regenerator C-2420, the lean-rich amine exchanger, E-2425A/B, the regenerator reboiler, E-2427A/B, the regenerator overhead fin fans, E-2420A/D, the regenerator reflux drum, V-2420 acid gas KO drum, V-2470 and the lean amine cooler, E-2426A/D. The C-430 overhead product sweet gas is routed to the TKC recycle gas compressor. The C-430 bottoms rich DEA amine

solution with the absorbed H_2S is routed to the rich DEA flash drum, V-2415, at 6 H_2S . From the flash drum the rich DEA continues to DEA regenerator, C-2420, at 6 H_2S . The regenerator utilizes a steam reboiler to remove the H_2S from the rich DEA. The regenerator OH product is H_2S and the bottoms product is the regenerated, or lean amine. The lean amine is then routed back to the TKC H_2S absorber. The H_2S is routed to the sulfur recovery unit.

With the new H_2S absorber in the TKC plant, this effectively increases the number of absorption units from four currently to five. A new regenerator vessel will accommodate the increased amine regeneration load. Therefore, there should be no change in amine loading at the existing plants. Chevron will continue to adhere to their Best Practice guidelines for all of their amine units, including the new amine system for TKC, which should maintain corrosion rates at existing setting levels.

1.9.5.1.1 General Amine Unit Materials of Construction and Damage Mechanism Discussion ⁷

Carbon steel, with a nominal corrosion allowance, has been used for most equipment in amine units that remove H_2S or mixtures of H_2S and carbon dioxide containing at least 5% H_2S . Some problems have been experienced with erosion-corrosion associated with circumferential welds in piping made of carbon steel. The problems were solved by reducing fluid velocity to less than 5 ft./sec. Austenitic stainless steels have been used in locations where the corrosion rate of carbon steel is excessive. Such locations include those that contact ho rich solutions with high acid gas loading, areas of high velocity, turbulence, impingement, vapor flashing, or two-phase flow, and most heat transfer surfaces operating above approximately 230°F. Austenitic stainless steels are usually employed extensively in amine units to remove carbon dioxide from hydrocarbon streams that contain very little or no H_2S . Clad plate is preferred over solid stainless steel construction to avoid possible through-wall cracking that results from chloride stress corrosion. In some locations, solid stainless steel construction is used where control of external chloride stress cracking was achieved. Alloys, such as Types 304 and 316, have been used for regenerator reboiler tubes that handle little or no H_2S . Titanium tubes have been used in units handling CO, but they may hydride in service. Carbon steels with a low level of inclusions, inclusion shape control, or both may provide improved resistance to hydrogen blistering, HIC and SOHIC. These steels should be evaluated for potential use in equipment that handles rich amine solutions, and in the regenerator overhead, especially cyanides are present. In some units, operating conditions in the bottom of amine absorbers or contactors are conducive to hydrogen damage despite relatively low temperatures. Carbon steels with a low level of inclusions or inclusion shape control might also be

⁷ API RP-945

useful in these locations. However, it should be noted that these steels are not immune to blistering and cracking. Austenitic stainless steel cladding, lining, or weld overlay can offer alternative methods of protection in areas where chronic cracking or hydrogen blistering occurs.

1.9.5.1.2 Corrosion

Potential damage mechanisms in amine service for carbon steel include corrosion and various environmental cracking mechanisms. Corrosion in carbon steel can occur due to degradation of the amine, especially MEA, or elevated levels of heat-stable amine salts (HSAS). High levels of dissolved carbon dioxide may also result in corrosion, especially when the carbon dioxide comes out of solution. Corrosion can be in the form of uniform metal loss, localized attack and/or pitting.

Carbon steel corrosion in amine treating processes is a function of a number of inter-related factors, the primary ones being temperature, the concentration of the amine solution and the acid gas content of the solution (“loading”).

Corrosion is a strong function of temperature with increasing temperature increasing corrosion. The high alkalinity of the amine minimizes corrosion until temperatures in excess of about 250°F are reached. Above 250°F, carbon steel corrosion is significant and special alloys and/or inhibitors are required.

The amine solution strength also influences corrosion. Amine solution strength is the sum of the free amine concentration and the amine tied up as heat stable salts. Industry guidelines and company experience indicate that the upper limits for DEA concentrations are about 25 to 30 wt.%. Above this level serious corrosion is often encountered because high concentrations require increased regeneration temperatures, which tend to degrade the amine.

Another important factor in amine corrosion is the presence of amine degradation products, usually referred to as HSAS. HSAS formed by the reaction between amine and acids or oxygen in the feed are detrimental to amine plants in several ways. First, they are corrosive to carbon steel. The salts also reduce the amine available to react with acid gases.

Acid gas loading is reported in terms of moles of acid gas per mole of active amine. A “rich” solution is amine of higher acid gas loading and “lean” solution has lower acid gas loading (typically < 0.1 mole/mole). To control corrosion and optimize plant operation, heat stable salt concentration in the amine should be monitored and limited. In $H_2S + CO_2$ systems, rich loading is often limited to 0.35 to 0.45 mole/mole. Chevron has their own proprietary amine best practice for controlling corrosion and environmental cracking in amine services. A review of Chevron’s best practice, as compared with published industry guidelines, such as

API-571 and API-581, show that the control limits in their best practice are similar to published values.

Secondary contributors to corrosion include high velocity/turbulence, two phase flow and solution cleanliness. Contamination or degradation of amine solutions can lead to serious corrosion and foaming. Operating and corrosion problems usually begin when the circulating solution gets dirty. For long, trouble-free solution life, it is necessary to recognize these problems and to know how to prevent them. Contaminants can be degradation products, heat-stable salts, oxygen, dissolved hydrocarbons, liquid hydrocarbons, and solids. Degradation of amines can occur by several mechanisms. Amines oxidize readily in the presence of oxygen and form corrosive organic acids. To prevent oxidation, the amine storage and surge vessels should be gas blanketed to keep air out of the system. Air leakage into a hot system (pump suctions) causes serious problems.

1.9.5.1.3 Environmental Cracking

Environmental cracking refers to corrosion cracking caused by a combination of conditions that can result in SSC, HIC associated with hydrogen blistering, SOHIC, or alkaline stress-corrosion cracking (ASCC). The first three mechanisms are more common in rich amines. ASCC found in amine applications is typically identified as amine cracking. The pH and temperature are lower in amine cracking than other ASCC mechanisms, i.e., caustic cracking. Amine SCC has been reported in MEA service at temperatures as low as 40C (100F) with un-stress-relieved carbon steel equipment.

Amine cracking is most often associated with lean amines in contact with welded carbon steels without a post weld heat treat. Amine cracking does not reportedly occur in fresh amine solutions and the likelihood of cracking in rich solutions is low.

1.9.5.1.4 New Amine Contactor/Regenerator Reliability Impacts.

As discussed in the above amine damage mechanism discussion section, the corrosion of metals and alloys commonly employed in amine systems is not based on the amine itself, but on corrosive species absorbed by the amine, most commonly CO₂ and H₂S. The mitigation and control of excessive corrosion is based on maintaining the amine solution under controlled conditions of solution strength, acid gas loading and heat stable salts amine salts. The selective use of corrosion resistant alloys (CRA's) and maximum amine velocities is also employed where necessary to control corrosion to acceptable levels. Chevron's Amine Best Practice Guidelines document (Chevron [n.d.2]) is used to monitor and control amine system parameters within specified limits to maintain corrosion within manageable (safe) limits. The Chevron Amine Best Practice document defines operating parameters for the amine units, including maximum amine loading (H₂S content) and velocities.

Chevron has assured that the amine units will continue to operate in compliance with their best practice guidelines. Compliance is assured by daily calculations for amine loading and velocity. These calculations are done in their Process Engineering (Process Monitoring and Optimization) PMO system. Inputs to the PMO calculations include laboratory data and process data. The laboratory results are based on a master sample schedule for each refinery unit. Each morning the sample schedule downloads sample tags to the respective control houses for that day's samples.

1.9.5.2 Amine Systems Recommendations

It is recommended that Chevron review ongoing sampling results (per Best Practice timing plus vendor sampling and reports) to determine if post-Modernization Project amine loading and HSAS are impacted by any increase in H_2S to the TKC Unit. This should be done prior to the commencement of Modernization Project operations.

1.9.6 Sulfur Recovery Unit

The only physical or operational change to the sulfur recovery unit that was considered to be impacted by the Project is the installation of small diameter liquid oxygen piping to the reactor burners via a new 304 stainless steel line. This is a physical change that will be addressed in an upcoming PHA re-validation. Therefore, the only recommendations believed necessary associated with the new liquid oxygen piping to mitigate risk are those typically associated with new construction and the special design and installation precautions associated with oxygen piping systems, i.e., design and installation best practice details common in industry for oxygen piping systems, including pre-commissioning cleaning of the piping interior to remove harmful materials such as dirt, debris, iron, grease and other contaminants known to cause ignition of pure liquid and gaseous oxygen.

1.9.7 Sour Gas Systems

Damage mechanisms in HP units have been discussed elsewhere. Excluded from the hydroprocessing scope, and covered separately in this section, are sour gas (fuel gas) streams from two and three phase separator vessels in the HP units, plus some smaller streams from the crude and SDA units.

The facility sour gas system refers to the piping networks that transfer sour gas from the HP units to the H_2S absorbers (amine units). The sour gas system basically becomes extinct upon entering the H_2S absorbers, as the amine in the amine contactors absorbs the H_2S from the feed gas into the amine in the unit. This system should not experience any change in corrosion activity as a result of feedstock changes from the Modernization Project. Sour water is covered in the next section.

1.9.7.1 Sour Gas Process Description

The sour gas system is the piping network that moves sour gas from the processing units to the H_2S absorbers in the Facility's sour gas plants. The South Yard plants in D&R (such as the crude unit) have their sour gas routed to the #5 H_2S plant. The fluid catalytic cracker unit in the North Yard routes all of its sour gas to the #3 H_2S plant. This plant is dedicated to just the fluid catalytic cracker to keep the olefins in that process gas segregated. The North Yard RLOP and hydro plants route their high pressure sour gas preferentially to the North Yard H_2S absorber at 20 plant. The 20 plant is the preferred routing for these streams because it has a PSA facility to recover the high hydrogen content. The portion of the RLOP and hydro high-pressure streams in excess of 20 plant capacity are sent to #4 H_2S . The medium and low pressure sour gas streams from hydro and RLOP will fill #4 H_2S to capacity with the excess routed to the South Yard #5 H_2S . The sour gas system basically becomes extinct upon entering the H_2S absorbers as the amine in the amine contactors absorbs the H_2S from the feed gas into the amine in the unit.

1.9.7.2 Materials

The sour gas streams contain varying amounts of H_2S and ammonia so ammonium bisulfide corrosion is the primary concern. The North Yard Sour Gas Handling Project, executed in 2005 through 2008, has significantly addressed ammonium bisulfide corrosion and has the refinery well postured for the impact of the Modernization Project. The sour gas project installed an ammonia scrubber, C-771, to remove ammonia from certain high ammonia content streams. It also installed a stainless steel line for handling "wet" streams that are operating near their water dewpoints. This stainless steel line extends from V-470 at the TKC to 4 H_2S and 20 plant. The remaining South Yard sour gas systems have much lower ammonia than the North Yard and therefore less ammonium bisulfide; these systems are essentially all carbon steel.

1.9.7.3 Damage Mechanisms

There are two primary corrosive constituents generated in HP units that can act as damage mechanisms in sour gas systems: (1) sulfur, which is converted to H_2S in the reactor; and (2) nitrogen, which is converted to ammonia in the reactor. The two corrosive species will combine to form ammonium bisulfide, based on stoichiometric availability and thermodynamic conditions. As H_2S is usually the predominant corrosive species in HP units, including the Chevron Richmond units, any excess H_2S will also be present in the vapor phase. Thus, ammonium bisulfide and wet H_2S corrosion are the potential damage mechanisms associated with sour gas systems.

The presence of liquid water is a requirement for both of the above damage mechanisms to be active. Under the right conditions of partial pressure and

temperature, ammonium bisulfide can condense from H_2S and ammonia in vapor phase streams downstream of the reactor. It can also be absorbed in a water phase downstream of water wash injection points. Ammonium bisulfide salt deposits are hygroscopic; therefore, can potentially absorb water from water vapor in the process vapor stream. The corrosivity of sour gas streams (and sour water) can potentially increase, based on post-Modernization Project conditions, from: (1) an increase in sulfur to the HP units; (2) an increase in nitrogen to the HP units; or (3) from an increase in both constituents.

1.9.7.3.1 Wet H_2S Damage

If the sulfur feed to an hydroprocessing (HP) unit increases, the H_2S content in the reactor outlet stream and thus, in the HP overhead system will increase. However, because the overhead piping and equipment operates at temperatures substantially below that where high-temperature sulfidation becomes a threat (~450F), any increase in H_2S will only be a threat if water vapor containing H_2S were to condense. Also, while the H_2S content of certain HP overhead systems will increase with the Project, the increase will not necessarily result in an increase in wet H_2S damage mechanisms, as these streams are already NACE sour under existing conditions. Therefore, based on an increase in post-Modernization Project sulfur and nitrogen to the HP units, the primary impacted damage mechanism in the sour gas streams will be that based on ammonium bisulfide corrosion. Wet H_2S corrosion in the sour gas piping will be covered under Chevron's existing wet H_2S inspection program.

1.9.7.3.2 Ammonium Bisulfide Corrosion

Any increase in H_2S will not cause an increase in ammonium bisulfide corrosion over existing conditions, as no more ammonium bisulfide can be formed than the amount of ammonia formed in the reactor, as ammonia is the controlling (limiting) species in the formation of ammonium bisulfide in the HP units. However, the amount of ammonium bisulfide in the sour gas can increase under Project conditions with an increase in ammonia content of the sour gas streams if not removed in the wash water, based on increased nitrogen to the HP reactor.

Ammonium bisulfide corrosion can manifest itself in several forms for carbon steel, low alloy steels and corrosion resistant alloys (CRA's) equipment and piping. Depending on the partial pressure of ammonia, H_2S and temperature, ammonium bisulfide can condense from a vapor phase to form a ammonium bisulfide salt that can deposit out on surfaces causing under-deposit corrosion and fouling. The ammonium bisulfide deposits are hygroscopic and can absorb moisture from a vapor stream creating a corrosive environment under the deposit. When condensed in a liquid water stream it can cause more uniform corrosion, with the corrosion rate increasing with increasing ammonium bisulfide concentration in the water and water velocities and turbulence.

Different HP reactor effluent water washing schemes result in either a low or moderate NH_3 level in each complex's sour gas stream. It is the high severity HP units that will generate the large amounts of H_2S and ammonia in their reactor effluent streams. RLOP/TKN/TKC are the sour gas producers at Chevron. In these units the preferential routing is to send the high pressure gas to the H_2S absorber at 20 plant. The high pressure gas that does not go to 20 plant is combined with medium pressure gas from RLOP and routed to the H_2S absorber at 4 H_2S . The excess medium pressure sour gas is routed to the South Yard and the H_2S absorber at 5 H_2S . The sour gas system basically becomes extinct upon entering the H_2S absorbers as the amine in the amine contactors absorbs the H_2S from the feed gas into the amine in the unit.

The sour gas system in the RLOP/TKN/TKC units includes pressure vessels and piping. The piping is considered more susceptible to corrosion damage, compared with the vessel, based on the relative amount of piping vs. equipment and the increased opportunity to reach dew point conditions, based on long runs of uninsulated piping. As previously mentioned formation of ammonium bisulfide salt condensed from a vapor stream is possible; however, the susceptibility to ammonium bisulfide condensation and the location of any potential salt formation can be predicted relatively easily using Figure A-1 in API - 932-B, Design, Materials, Fabrication, Operation, And Inspection Guidelines For Corrosion Control In Hydroprocessing REAC Systems.

The analysis included foreseeable nitrogen levels, including those under the more probable P-50 sulfur case and the improbable P-90 sulfur case, which includes a nitrogen range of 1138 ppm to 1541 ppm. Additionally, because the analysis in *Appendix 4.3-MET* concludes that "it is likely that the crude oils processed by the Refinery if the Modernization Project is implemented have the potential to contain additional nitrogen", a sensitivity analysis was completed that evaluated nitrogen levels at much higher levels (up to 1877, or 22% higher than the high nitrogen case of 1541 ppm).

The elevated nitrogen case of 1877 ppm will increase the ammonia content of the RLOP and TKN high pressure sour gas streams. For the ammonium bisulfide condensation evaluation it was assumed that the post-Modernization Project ammonia content will increase by 50%, which is the increase in LNC and HNC feed nitrogen. Using Figure A-1 in API-932-B, the salt formation temperature was calculated at 40F. The RLOP stream operates well over 100F; therefore ammonium bisulfide salt formation from the RLOP sour gas is considered unlikely. The TKN sour gas NH_4HS salt formation temperature was calculated at 52 F and the TKN sour gas stream operates above 160 F; therefore ammonium bisulfide salt deposits in the TKN sour gas stream is also considered unlikely. The ammonia content of the TKC sour gas is orders of magnitude less than TKN (32 ppm vs. 1400 ppm); therefore ammonium bisulfide salt formation from TKC sour

gas is even less likely than in TKN or RLOP. Therefore, corrosion from ammonium bisulfide salt formation in the high severity sour gas systems is considered to be highly unlikely with the much higher sour gas operating temperatures compared with calculated salt formation temperatures and considering the relatively high, mean low atmospheric temperatures in the Richmond, CA area.

The other potential post-Modernization Project damage mechanism for sour gas is corrosion by ammonium bisulfide at water dew point conditions. Recognizing this potential in the higher severity sour gas HP units Chevron has upgraded some carbon steel piping containing sour gas at relatively high water dew points to stainless steel where water condensation was expected to occur. Thus, there is a mix of carbon steel piping and stainless steel piping handling sour gas to the H₂S absorbers. As Chevron has not conducted water dew point calculations for all carbon steel sour gas piping on a P&ID level and there could still exist small diameter tie in lines, dead legs and low points in the piping where sour water could condense, the actual risk of corrosion in the sour gas system is not known with certainty. Therefore, it is prudent to assume that some sour gas carbon steel piping is at risk and institute mitigation steps to minimize this risk.

1.9.7.4 Sour Gas Recommendations

1. Based on the potential risk of ammonium bisulfide corrosion in carbon steel due to the possibility of the sour gas condensing at locally cool portions of piping, Chevron should develop and implement a mitigation plan for this eventuality. The mitigation plan is to include reviewing sour gas P&IDs and isometric drawings to locate low points where water could accumulate, locate dead legs and establish inspection/monitoring plans for verifying if and where water is condensing out of the vapor phase. This should be conducted within 1 year of commencement of Modernization Project start-up.
2. Chevron should conduct a review to confirm their post-Modernization Project assumptions made during this review regarding ammonium bisulfide concentrations, dew points and potential for salt condensation in the sour gas piping, at the 2.25 wt. % and 2.75 wt. % average annual sulfur content trigger points.
3. Develop IOWs per draft API -584 for identified damage mechanisms for the sour gas system. These IOWs should be established prior to the commencement of Modernization Project operations.

1.9.8 Sour H₂O Systems and Plants (WWT)

1.9.8.1 Process Description

The sour water systems (in some cases “WWT” is used in Chevron terminology) includes the sour water vessels and piping from the Chevron HP units that collect

the sour water from the accumulator water boots and transports it to the sour water stripper for stripping of H_2S and ammonia from the water. The “stripped sour water” then can be reused as wash water in various refining units requiring a non-corrosive water for water washing, including HP units and the crude unit.

The sour water piping system is depicted in two block diagrams shown in Figure A4.13-REL-16 and Figure A4.13-REL-17. These diagrams show the concentrated sour water from the LNC, HNC, TKC and TKN flow through degassers and on to concentrated sour water tankage in TK-3220. Also combining in TK-3220 is a concentrated sour water stream from the sour water concentrators. The sour water concentrators process an accumulation of many dilute sour water streams with an estimated NH_4HS content of 0.6 wt.%. This is below the threshold of where ammonium bisulfide is considered to be corrosive in carbon steel piping. The sour water concentrators generate a bottoms product suitable for effluent water and an overhead product of concentrated sour water. TK-3220 concentrated sour water serves as feed to both sour water plants (i.e., #8 Plant and #18 Plant, which operate in parallel). The high nitrogen crude sensitivity case is projected to raise the NH_4HS content of the feeds to the sour water plants by an estimated 12% over the 2012 baseline. That baseline NH_4HS content was 8.4 wt.%, which brings the high nitrogen case NH_4HS to 9.4 wt.%. From tankage the sour water is routed to the sour water stripper (SWS) for further processing. In all cases, the sour water streams in the block diagram are within Chevron’s HP-002 BP guidelines (Chevron [n.d.3]) for controllable corrosion rates.

1.9.8.2 Sour Water Damage Mechanisms

The primary damage mechanisms in the sour water system and WWT plants are ammonium bisulfide (sour water) corrosion and wet H_2S cracking. The corrosivity of sour water primarily depends on: (1) the concentration of ammonium bisulfide in the water, typically expressed as wt. %; (2) the H_2S partial pressure and, (3) the liquid velocity or shear stress imposed on the piping wall. Even though sour water can be corrosive, the sour water boots of separation vessels and sour water piping to offside processing in the Facility's hydroprocessing plants is successfully handled in carbon steel piping due to the low velocities. A combination of Hastelloy, stainless steel and carbon steel piping are employed in the #8 Plant and #18 Plant.

1.9.8.3 Damage Mechanism Mitigation Discussion

Corrosion due to sour water is typically mitigated by controlling velocity and/or using alloys to resist higher combinations of ammonium bisulfide or velocity. Much of this type of knowledge is captured in API -932-B. The majority of the corrosion concerns in Chevron’s WWT plants are in the overhead systems of the NH_3 stripper column where NH_4HS corrosion can be a concern and secondarily the H_2S stripper column where H_2S goes out the top of the stripper column. In the

sour water plants, the ammonia stripper overhead condenser tube metallurgies are either Titanium (#8 Plant) or Hastelloy (#18 Plant) to resist ammonium bisulfide corrosion. Additionally, the piping from the NH_3 stripper overhead condensers to the stripper accumulator is Hastelloy.

1.9.8.4 Sour Water Systems Recommendations

1. The block diagrams shown in Figure A4.13-REL-16 and Figure A4.13-REL-17 do not include detailed information at the P&ID level. Also, information is lacking on the sour gas streams in the overhead of the H_2S and NH_3 strippers in the SWS unit. (However, for purposes of the review the overhead systems of the WWT plants were deemed to be out of scope.) The impact of post-Modernization Project corrosion from sour water corrosion should be minimal, based on the Reviewer's analysis of the sour water streams. However, based on a lack of detail at the P&ID level Chevron should conduct a review of their sour water piping inspection programs at the P&ID/Inspection Isometric level (including to ensure that low points, galvanic metal couple locations and CMLs are properly captured) to ensure that their program is sufficient to detect any ammonium bisulfide corrosion in the system. This should be completed prior to the commencement of Modernization Project operations.
2. Chevron should conduct monitoring and sampling to confirm their assumptions regarding the ammonium bisulfide concentrations and velocities in the sour water piping and H_2S concentrations in the H_2S Stripper and NH_3 Stripper overhead systems. This review should be conducted when average annual sulfur content levels reach 2.25 wt. % and again at 2.75 wt. %.
3. The H_2S stripper, NH_3 stripper, ammonia stripper overhead condenser, and ammonia stripper reflux drum are all Category 2 Wet H_2S vessels and therefore are included in Chevron's wet H_2S program. If a post-Modernization Project review of the assumptions regarding the severity of wet H_2S damage in the overhead systems warrants a change in the categorization of the overhead wet H_2S vessels, then a wet H_2S cracking inspection should be conducted. This should be conducted within one year after commencement of Modernization Project operations.
4. Continue as with the existing condition inspection, the X-ray and/or close-grid UT inspection techniques for all of the overhead piping from the NH_3 stripper to the reflux drum, regardless of metallurgy.
5. Develop IOWs per draft API -584 for identified damage mechanisms for the sour water system. The IOWs should be established prior to the commencement of Modernization Project operations.

1.9.9 Recovered Oil

1.9.9.1 Recovered Oil Process

The Facility recovered oil system includes two systems, D&R recovered oil that is processed in the crude unit, and North Yard (NY) recovered oil which includes cracking and hydroprocessing sources and is processed in the TKC Fractionator, C-710. The NY recovered oil is derived from the fluid catalytic cracker, hydroprocessing (RLOP, TKC/TKN/ISO), and SDA units. The HP units generate recovered oil in the reactor effluent water wash process. The SDA unit is also a contributor to NY recovered oil.

1.9.9.2 Damage Mechanism Impact Analysis

The D&R recovered oil is recovered from the crude unit desalter as an oil/water emulsion layer. The recovered oil is injected into the flash drum vapor stream from V-1103 which then enters the flash zone of the C-1100 atmospheric tower at nozzle NI7. This recovered oil will contain the same amount of sulfur as being fed to the unit and will also include organic and inorganic chlorides from the desalter that will not be captured by the desalter and will travel overhead in the crude unit, potentially contributing to HCL and ammonium chlorides in the overhead water. The V-1103 vapor stream typically is 295°F and the recovered oil is at ambient temperature. The temperature of the tower where the combined recovered oil/V-1103 vapor stream enters is 685°F, but the nozzle is overlaid with 300 series stainless steel and this portion of the tower is clad with 410SS; therefore, no sulfidation corrosion is expected at the injection location of the D&R recovered oil stream because of the stainless steel metallurgy. Chlorides in the recovered oil would hydrolyze to HCL in the crude charge furnace and travel overhead where they would either condense out in the wash water or combine with ammonia to form ammonium chlorides. The HCL or ammonium chlorides would be mitigated in the same manner as the residual chlorides in the desalted crude going to the crude tower by the ammonia additions and by dilution from the crude tower overhead wash water. In either case, corrosion due to chloride salts was not considered to be a post-Modernization Project damage mechanism(s) as chlorides were shown to not be correlated with increased sulfur or lower API gravity feeds.

The post-Modernization Project NY recovered oil will also not cause an increase in corrosion severity as the fluid catalytic cracker feed sulfur will not increase from the existing setting specification requirements. For the same reason the sulfur level in the HP units downstream of the reactor will not change with the Modernization Project. Therefore, any increase in sulfur in the NY recovered oil should not result in an increase in post-Modernization Project corrosion.

The sulfur content of the SDA feed will increase with the Modernization Project. However, the hydrocarbon stream from the SDA unit comprising the recovered

oil would be the pentane solvent which has negligible sulfur. Therefore, since the sulfur levels in the NY recovered oil will not change, the corrosion rate of the injection location in to C-710 should not increase.

1.9.9.3 Recovered Oil Recommendations

If not already present, add CML locations to the C-710 injection nozzle and adjacent C-710 tower shell so that the assumptions regarding post-Modernization Project corrosion rates not increasing in severity can be verified. Implement prior to the operational startup of the Modernization Project.

1.10 SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

1.10.1 Overall Conclusions and Recommendations

In addition to the specific technical recommendations corresponding to each process unit, the Reviewer made several general observations and recommendations of broader applicability, as follows⁸:

Observation: The Facility has many sound appropriate procedures, best practice documents and technically qualified corrosion and materials engineering personnel to manage damage mechanisms associated with existing setting and post-Modernization Project refining processes.

Observation: Chevron's subject matter experts (SME's), who are primarily responsible for understanding and advising on damage mechanisms and their prevention, show a strong commitment to this responsibility.

1. Recommendation: Chevron should ensure that its organizational communication procedures and work processes incorporate mechanisms by which risk concerns, corrective actions, and recommendations that are identified (e.g., during inspections, turnarounds, audits, PHAs, etc.) by personnel (or contractors) are addressed, reviewed and authorized by management as appropriate, tracked, and closed out, and that the rationale for any decision not to implement a recommendation or corrective action, or otherwise address a risk concern, is clearly documented.
2. Recommendation: Chevron should further clarify and incorporate into its mechanical integrity program and program documents periodic reviews of work processes, procedures, inspection strategies, etc. to account for physical, operational and organizational changes over time, that could affect the assumptions that went into the original decisions. Examples that

⁸ The Reviewer has been informed by Chevron that the Facility is implementing corrective actions, resulting from the August 6, 2012 fire, that Chevron asserts address, at least in part, the recommendations below. The Reviewer did not independently review these corrective actions or the status of their implementation, so does not reach a conclusion regarding their adequacy to address the recommendations.

illustrate this include: (1) periodic reviews of inspection CML densities and placements to ensure that unpredictable damage mechanisms can be detected; and (2) reviews of wet H₂S damage risk, based on crude feed constituent changes. Chevron reports - though this Reviewer did not independently verify - that Chevron is developing "asset strategy plans" for each process unit, and that the development of the asset strategy plans will address this recommendation by including review of inspection procedures, working documents, CMLs, and damage mechanisms, and that the asset strategy plans will identify and implement changes needed to each as a result of the review. Whether called an "asset strategy plan" or otherwise included in another safety program (e.g., included as part of the Richmond Industrial Safety Ordinance documentation), Chevron should clarify its implementation tracking process for changes needed as a result of these periodic reviews.

3. Recommendation: Chevron should leverage its existing infrastructure and technology to lessen the reliance on human interaction in responding to potential risks, including for example Chevron's current pilot project to implement Integrity Operating Windows per the guidelines of the draft API-584 Recommended Practice for the crude unit. Chevron should extend the pilot project to the remaining operating units.
4. Recommendation: Chevron should review its Positive Material Identification (PMI) Procedure for compliance with API-578, Material Verification Program for New and Existing Alloy Piping Systems, based on PMI inspection of equipment and piping during shutdown/ dismantling/disassembly, and make revisions, as warranted, to ensure that Chevron's PMI Procedure conforms to API-578.
5. Recommendation: Chevron should review and modify its Piping Inspection Procedure to incorporate an engineering review of thickness inspection data with near term "Flag" dates for high risk equipment/piping to assure that the actual minimum thickness associated with the Flag date has either been verified through inspection or, alternatively, the inspection data analyzed with techniques such as a statistical analysis (95% CL or extreme value analysis) to evaluate what risk is involved if the actual minimum thickness was not measured.

1.10.2 Specific Recommendations

The following recommendations for specific processes should be implemented prior to commencement of post-Modernization Project operations, unless otherwise indicated.

1.10.2.1 Crude Unit Recommendations

The operational and feedstock changes contemplated by the Modernization Project have the potential to increase the risk of accidental release of hazardous

substances associated with increasing damage mechanism activity. Specifically, increases in sulfur content of feedstocks, increased hydrogen purity produced by the new hydrogen plant, or increased H₂S partial pressures in hydroprocessing plants recycle streams could all contribute to increased damage mechanism activity post-Modernization Project, thereby warranting the implementation of the following preventive measures.

1. Based on the results from the F-1100 radiant tube sulfidation analysis, Chevron should monitor the post-Modernization Project sulfur content being fed to the crude unit and use a 2.0 wt. % sulfur content of feed as a trigger to conduct a review of the F-1100 crude charge furnace to study whether the 5Cr radiant tubes are safe to operate until the 2017 shutdown.
2. Chevron's analysis of the atmospheric column furnace F-1100 does not include conclusive evidence as to the present creep/stress-rupture condition of the tubes. Therefore, it is believed that some additional actions are required in order to lower the risk of a creep/stress-rupture or sulfidation failure in a F-1100 tube under post-Modernization Project operating conditions. Acceptable options to lower the risk of heater tube failures include:
 - Furnace F-1100: Option 1, complete all of the following actions:
 - Complete a full internal tube inspection for F-1100 during the 4th quarter 2017 crude unit turnaround using intelligent pigs.
 - Conduct testing on the two currently available, radiant section tubes from the F-1100 Furnace to verify their existing metallurgical, physical and mechanical properties, plus remaining creep life using accelerated Omega creep testing as an input to decide whether the F-1100 furnace should be retubed during the 2017 shutdown.
 - Conduct additional metallurgical, physical, mechanical and Omega creep testing on radiant furnace tube samples to be removed during the 2017 shutdown, depending on the results of the Omega testing planned for the 2012 furnace tube samples.
 - In 2017, replace tubes as needed in F-1100, per Chevron's replacement criteria for furnace tubes. The replacement criteria are based on the minimum furnace tube thickness on the furnace Safety Instruction Sheet and remaining wall thickness collected by intelligent pig data.

- Install at least three Permasense® continuous monitoring ultrasonic thickness gauge monitors in each of the furnace outlet systems. If the monitors indicate an increase in corrosion rates greater than 5 mpy, review the need for additional mitigation actions.
 - Furnace F-1100: Option 2:
 - Retube the F-1100A/B furnace during the 2017 turnaround with 9Cr or higher alloy tubes.
3. The vacuum column furnace, F-1160, is constructed of 5Cr radiant furnace tubes. The recommended actions for this furnace are as follows:
 - Complete a full internal tube inspection for F-1160 during the 2017 crude unit turnaround using intelligent pigs.
 - In 2017, replace tubes as needed in F-1160 per Chevron's replacement criteria for furnace tubes. The replacement criteria are based on the minimum furnace tube thickness on the furnace Safety Instruction Sheet and remaining wall thickness collected by intelligent pig data.
 4. Conduct laboratory analyses to more accurately determine crude and crude blend sulfur speciation and H₂S evolution, which could be used to predict likely crude corrosion rates. This should be done by the end of the fourth quarter of 2015.
 5. Develop integrity operating windows (IOWs) for critical crude unit operating parameters per the guidelines in the draft version of API-584. This should be done by the end of the third quarter of 2014.
 6. The Crude Splitter software is used to predict the distribution of the sulfur in the atmospheric tower sidecut and bottom streams. Verify the Crude Splitter predicted sulfur results with post-Modernization Project data on the sulfur-containing streams within the first year of operation following the implementation of the Modernization Project if the trigger points (2.25 wt. % sulfur and 2.75 wt. % sulfur) noted in the Modernization Project Reliability Program are reached.
 7. Revise the asset integrity plans for the crude unit atmospheric column reflux drum (V-1100), the stabilizer column reflux drum (V-1190), and the vacuum column overhead seal drum (V-1160), to include inspection for wet H₂S damage. An external automatic ultrasonic testing inspection of representative sections of the "water wet" portions of V-1100, V-1160 and (V-1190) vessels should be conducted as a baseline before the start of post-Modernization Project conditions, then checked externally again

approximately one year after the start of the Modernization Project conditions. In addition, a one-time internal inspection should be conducted of these vessels during the scheduled maintenance turnaround after the start of Modernization Project conditions, using eddy current or other approved internal inspection techniques per the Chevron Wet H₂S program.

8. Develop a process monitoring plan for the crude unit overhead to confirm any impacts of the increased sulfur levels. The monitoring plan should be implemented post-Modernization Project and should include:
 - Process sampling of the accumulator for pH, chlorides, iron and H₂S content. Compare to established IOWs;
 - Monitor desalter pH;
 - Analyze the atmospheric tower post-Modernization Project to quantify if, and how much, increased H₂S is in the overhead system resulting from the increased sulfur feed to the unit;
 - Higher mercaptan crudes could lead to increased sulfidation corrosion rates in the jet or kerosene cuts. Modify asset integrity plans to monitor for potential increased corrosion if higher mercaptan crudes are run compared with current and historic crude and crude blends; and
 - Review the asset integrity plan to ensure that the Permasense continuous ultrasonic monitoring locations are properly placed to ensure early detection should corrosion rates increase significantly beyond expectations per the McConomy curve predicted rates.
9. The reliability review for the Modernization Project has identified seventeen (17) piping circuits in the crude unit that warrant replacement based on post-Modernization Project operation conditions. The Facility has committed to accelerating the replacement of these circuits during the next scheduled turnaround for the crude unit, no later than end-of-year (EOY) 2017, as detailed above in Section 1.9.2.8.5, High Temperature (HT) Sulfidation, Table A4.13-REL-5.

The reliability review for the Modernization Project has also identified four partial piping and valve replacements in the crude unit that warrant replacement based on reasonably foreseeable post-Modernization Project operating conditions. Chevron has committed to accelerating the replacement of these partial components during the next scheduled turnaround for the crude unit, no later than end-of-year (EOY) 2017, as

shown above in Section 1.9.2.8.5, High Temperature (HT) Sulfidation, Table A4.13-REL-6.

10. As with all piping circuits in the Facility, new 9Cr circuits should be regularly monitored and inspected. Beginning one year from commencement of Modernization Project operations, the Facility should provide annual reports to the City summarizing the monitoring and inspection results for the identified circuits as noted above. These reports shall, at a minimum, include the following information:

- A list of all piping circuits identified as potentially susceptible to sulfidation corrosion, including specifically piping circuits identified during the reliability review for the Modernization Project as being susceptible to sulfidation corrosion and subject to potential process changes;
- A list of components identified through the 100% component inspection conducted following the August 6, 2012 incident pursuant to the methodologies set forth in the *API-939-C - Guidelines for Avoiding Sulfidation (Sulfidic) Corrosion Failures in Oil Refineries* and *Updated Inspection Strategies for Preventing Sulfidation Corrosion Failures in Chevron Refineries* (API-939-C, 2009) that may lack sufficient thickness to remain in service until the next scheduled turnaround;
- A description of the solutions implemented with respect to components of insufficient thickness identified above;
- A description of the current fixed inspection frequency for carbon steel piping circuits identified as potentially susceptible to sulfidation corrosion;
- A description of any findings from inspection and monitoring of the piping circuits identified during the reliability review for the Modernization Project as being susceptible to sulfidation corrosion and subject to potential process changes that indicate that any of these circuits lack sufficient thickness to remain in service until the next turnaround, and a description of the solution to be implemented with respect to these circuits.

11. Chevron shall obtain all required permits for replacement of these piping circuits pursuant to the California Building Standards Code, inclusive of the California Fire Code, and, once the piping circuits are replaced, shall submit copies of closed permits to the Planning Department to demonstrate compliance with this commitment.

12. Re-evaluate and report on the validity of post-Modernization Project operating and process assumptions made during the reliability review. The reliability review for the Modernization Project assumed that certain operating conditions would exist once the Project is implemented, including projected temperatures, sulfur levels, and corrosion rates for various process units and individual piping circuits. These assumptions were based on either the P50 sulfur case or a conservative 3.28 wt. % (P90) sulfur case. In order to verify that the assumptions made during the reliability review were accurate, the Facility will undertake the following actions:

- When the sulfur weight percent of crude oil processed at the Facility reaches 2.25 wt. % sulfur on an annual average, and the again when it reaches 2.75 wt. % sulfur annual average, the Facility shall:
 - Assemble a reliability review team that will be made up of appropriate subject matter experts (SMEs), including a Senior Process Engineer, Senior ETC Materials and Corrosion Engineer, Refinery Materials Engineer and Process Operator;
 - For all damage mechanisms identified as being affected by the Project, and using then-current inspection and/or monitoring data, the reliability review team shall review, analyze, and, as necessary, update, the data and conclusions prepared during the reliability review for the Modernization Project to determine whether the assumptions made and conclusions reached during the reliability review accurately reflect actual post-Modernization Project operating conditions.
 - Review any changes associated with sulfur speciation that have resulted from the Modernization Project.
 - Review any operational or process changes that have occurred post-Modernization Project.
 - Make recommendations concerning material upgrades and/or enhanced inspection opportunities as necessary, based on the re-evaluation.
 - Report on the results of this re-evaluation and any resulting recommendations.

13. Installation and Monitoring of Additional Permasense® Monitors on Identified Circuits

Since the beginning of 2013, the Facility has installed a total of 117 Permasense® probes in the crude unit on six piping systems consisting of

carbon steel, 5 Chrome, and 9 Chrome materials. Permasense® is the trade name of a type of high-temperature ultrasonic device that is mounted on a pipe or vessel, and penetrates through insulation. It has wireless sensors that provide periodic equipment thickness readings (at variable intervals, but currently set to collect thickness data twice-a-day) to monitor a system. Due to noise and sensitivity, the technology is limited to longer-term trending (days and months vs. hours), which is appropriate for piping subject to sulfidation conditions with its predictable rates.

The six piping systems on which the sensors were installed, were chosen based on past and projected operating conditions. The wireless probes collect pipe wall thickness data while the plant is operating, and are used to monitor corrosion rates. This long-term online monitoring program will be part of the reliability program to ensure safe operation of equipment after the Modernization Project commences operation. Thirteen of these piping circuits with Permasense® monitors installed have been identified for replacement and will be upgraded to 9 Chrome pursuant to the planned piping circuit upgrades described above and the Permasense® monitors will not be reinstalled on these circuits. In addition, as part of the Modernization Project, the Facility will install at least 25 additional Permasense® monitors on carbon steel circuits in the SDA unit. These sensors are being installed to confirm the predictive model results that there will be little-to-no sulfidation corrosion in the SDA unit post-Modernization Project.

Data from the Permasense® monitors will be utilized in the reporting obligations.

14. Develop and implement physical or administrative controls to assure that carbon steel piping components downstream of high sulfur streams operating > 500°F are not inadvertently placed into continuous (e.g., placement of a warning tag, locked valve, double-block-and-bleed valves or other measures). This should be completed prior to the commencement of Modernization Project operations.
15. Higher mercaptan crudes could lead to increased sulfidation corrosion rates in the jet or kerosene cuts. Conduct a historical review of purchased crudes and processed crude blends for the 90% confidence level of highest mercaptans processed and use this statistical number to set a review flag in the crude and gas oil acceptance procedure. If higher mercaptans crudes are run at the Facility, review the Permasense® corrosion rate data from this time period as part of the crude management of change lookback. This should be completed prior to the commencement of Modernization Project operations.

16. Add corrosion monitoring locations (CMLs) to the crude unit atmospheric column overhead piping (circuit 0955-003-001) at the termination of the Hastelloy internal overlay. This should include the termination of cladding in the vertical section of piping, as well as the termination point at the inlet to the E- 1101's. Review other, similar locations in the crude unit for missing dissimilar metal interface thickness monitoring locations (TMLs). This should be completed prior to the commencement of Modernization Project operations.

1.10.2.2 Hydroprocessing Recommendations

1. At the 2.25% wt. % sulfur in crude feed trigger point, evaluate and modify as warranted, based on any increased sulfur in this section of the unit, inspection plans (what, where and how often) for the distillation section of the HP units where sulfidation corrosion rates have been “erratic” and uncertain, per API-939-C.
2. Report on the progress of the project to compare the HP-002 Best Practice Guideline regarding water wash to API-932-B recommendations to ensure that the HP-002 document is consistent with 932-B guidelines. This report should be submitted prior to the commencement of Modernization Project operations.
3. Conduct process monitoring and sampling for post-Modernization Project operations for all HP units, to develop process data to confirm assumptions made during the damage mechanism review regarding amounts of H₂S and ammonium bisulfide in the overhead systems. This shall be completed after commencement of Modernization Project operations.
4. Develop IOWs for the HP units to incorporate existing critical reliability variables such as the wash water rate for NH₄HS corrosion control. The IOWs shall be established prior to the startup of Modernization Project operations.
5. If the REAC Corrosion Control Project (TKN) is not completed pre-Modernization Project, conduct a review of current operations to ensure that corrosion rates will remain under REAC best practice guidelines with any increase in sulfur to the unit. This shall be completed prior to the startup of Modernization Project operations.

1.10.2.3 SDA Recommendations

1. Verify post-Modernization Project conditions regarding H₂S content in the SDA overheads and target one or more “water wet” vessels for inspection using internal eddy current, external automatic ultrasonics (AUT) or other non-destructive evaluation (NDE) techniques appropriate for wet H₂S cracking detection within one year of operation under post-Modernization Project conditions.

2. Conduct water boot analysis for corrosive constituents similar to that conducted in the crude unit on the unit overhead accumulator drums, including cyanides. This should be conducted at the 2.25 wt. % and 2.75 wt. % sulfur trigger points.
3. When the sulfur wt. % of crude oil processed at the Facility reaches 2.25 wt. % sulfur on an annual average, and again when it reaches 2.75 wt. % sulfur annual average, the Facility shall trigger the same responses for the SDA plant as described in the recommendation section for the crude unit.
4. Conduct a follow-up smart pig inspection of F-100 and F-120 furnace tubes during the first planned maintenance after the unit has seen at least 1 year of post-Modernization Project operating conditions.
5. Install at least 25 additional Permasense® monitors on carbon steel circuits in the SDA unit including sulfidation “dead legs,” based on a critical review of historical corrosion rates. These sensors will confirm the predictive model results that there will be little-to-no increase in sulfidation corrosion in the SDA post-Modernization Project. These installations should be completed prior to the commencement of Modernization Project operations.
6. Develop IOWs per draft API -584 for identified damage mechanisms in the SDA unit. The IOWs should be established prior to the commencement of Modernization Project operations.
7. Develop process monitoring and sampling plans for post-Modernization Project operating conditions to confirm assumptions made during the damage mechanism review project. The monitoring and sampling plans should be developed prior to the commencement of Modernization Project operations, and should be implemented after commencement of Project operations, following an increase in sulfur content to the SDA unit.

1.10.2.4 Amine Systems Recommendations

It is recommended that Chevron review ongoing sampling results (per Best Practice timing plus vendor sampling and reports) to determine if post-Modernization Project amine loading and heat stable amine salts (HSAS) are impacted by any increase in H₂S to the TKC Unit. This should be done prior to the commencement of Modernization Project operations.

1.10.2.5 Sulfur Recovery Unit Recommendations

Associated with the new liquid oxygen piping, the Facility shall design and build new construction in conformance with the special design and installation precautions associated with oxygen piping systems, i.e., design and installation best practice details common in the industry for oxygen piping systems, including pre-commissioning cleaning of the piping interior to remove harmful

materials such as dirt, debris, iron, grease and other contaminants known to cause ignition of pure liquid and gaseous oxygen.

1.10.2.6 Sour Gas System Recommendations

1. Based on the potential risk of ammonium bisulfide corrosion in carbon steel due to the possibility of the sour gas condensing at locally cool portions of piping, Chevron should develop and implement a mitigation plan for this eventuality. The mitigation plan is to include reviewing sour gas P&IDs and isometric drawings to locate low points where water could accumulate, locate dead legs and establish inspection/monitoring plans for verifying if and where water is condensing out of the vapor phase. This should be conducted within 1 year of commencement of Modernization Project start-up.
2. Chevron should conduct a review to confirm their post-Modernization Project assumptions made during this review regarding ammonium bisulfide concentrations, dew points and potential for salt condensation in the sour gas piping, at the 2.25 wt. % and 2.75 wt. % average annual sulfur content trigger points.
3. Develop IOWs per draft API -584 for identified damage mechanisms for the sour gas system. These IOWs should be established prior to the commencement of Modernization Project operations.

1.10.2.7 Sour Water System Recommendations

1. The block diagrams shown in Figure A4.13-REL-16 and Figure A4.13-REL-17 do not include detailed information at the P&ID level. Also, information is lacking on the sour gas streams in the overhead of the H₂S and NH₃ strippers in the SWS unit. (However, for purposes of the review, the overhead systems of the WWT plants were deemed to be out of scope). The impact of post-Modernization Project corrosion from sour water corrosion should be minimal, based on the Reviewer's analysis of the sour water streams. However, based on a lack of detail at the P&ID level Chevron should conduct a review of their sour water piping inspection programs at the P&ID/Inspection Isometric level (including to ensure that low points, galvanic metal couple locations and CMLs are properly captured) to ensure that their program is sufficient to detect any ammonium bisulfide corrosion in the system. This should be completed prior to the commencement of Modernization Project operations.
2. Chevron should conduct monitoring and sampling to confirm their assumptions regarding the ammonium bisulfide concentrations and velocities in the sour water piping and H₂S concentrations in the H₂S Stripper and NH₃ Stripper overhead systems. This review should be conducted when

average annual sulfur content levels reach 2.25 wt. %, and again at 2.75 wt. %.

3. The H₂S stripper, NH₃ stripper, ammonia stripper overhead condenser, and ammonia stripper reflux drum are all Category 2 Wet H₂S vessels and therefore, are included in Chevron's wet H₂S program. If a post-Modernization Project review of the assumptions regarding the severity of wet H₂S damage in the overhead systems warrants a change in the categorization of the overhead wet H₂S vessels, then a wet H₂S cracking inspection should be conducted. This should be conducted within one year after the commencement of Modernization Project operations.
4. Continue as with the existing condition inspection, the X-ray and/or close-grid UT inspection techniques for all of the overhead piping from the NH₃ stripper to the reflux drum, regardless of metallurgy.
5. Develop integrity operating windows (IOWs) per draft API-584 for identified damage mechanisms for the sour water system. The IOWs should be established prior to the commencement of Modernization Project operations.

1.10.2.8 Recovered Oil Recommendations

If not already present, add CML locations to the C-710 injection nozzle and adjacent C-710 tower shell so that the assumptions regarding post-Modernization Project corrosion rates not increasing in severity can be verified. Implement prior to the operational startup of the Modernization Project.

APPENDIX 4.16

Traffic – Technical Data

MEMORANDUM

Date: February 26, 2014

To: Lynette Dias and Elizabeth Boyd, Urban Planning Partners

From: Sam Tabibnia

Subject: Traffic Impact Analysis for Chevron Facility Modernization Project EIR

WC11-2951

This memorandum summarizes the traffic impact analysis completed by Fehr & Peers for the Chevron Facility Modernization Project EIR. The memorandum summarizes existing traffic conditions in the project vicinity, and estimates trip generation and evaluates impacts on traffic operations at intersections in the project vicinity during project construction and after completion of project construction. This memorandum also identifies significant impacts, recommends improvements to mitigate those impacts, and identifies traffic volume thresholds that trigger those impacts and associated mitigation measures.

1. Study Area

Fehr & Peers analyzed traffic operations at the following 11 intersections, shown on **Figure 1** (All figures are provided at the end of this document), as part of this evaluation:

- | | |
|--|--|
| 1. Chevron Way/Marine Street | 7. Castro Street/Mills Street (Gate 31) |
| 2. Castro Street/Tewksbury Avenue | 8. Castro Street/Richmond Lane/General Chemical Access (Gate 91) |
| 3. Marine Street/I-580 Eastbound Ramps | 9. Castro Street/Hensley Street |
| 4. Castro Street/I-580 Eastbound Ramps | 10. Richmond Parkway/Hensley Street |
| 5. Castro Street/Chevron Way | 11. Richmond Parkway/Gertrude Avenue |
| 6. Castro Street/I-580 Westbound Ramps (Gate 14) | |

These intersections were selected because they provide access to the project site and would most likely be impacted by the project construction or project operations.

2. Analysis Methodology

Study intersection operations were evaluated using level of service (LOS) calculations. To measure and describe the operational status of a local roadway network, transportation engineers and planners commonly use a grading system called level of service (LOS). LOS is a description of a transportation facility's operation, ranging from LOS A, indicating free-flow traffic conditions with little or no delay experienced by motorists, to LOS F, which describes congested conditions where traffic flows exceed design capacity, resulting in long queues and delays.

This evaluation uses the Transportation Research Board's 2000 *Highway Capacity Manual* (HCM) method to analyze intersection operations at all signalized and unsignalized study intersections. The Synchro Software was used to estimate delay and LOS for all signalized and unsignalized study intersections. Synchro uses the equations provided in 2000 HCM to calculate control delay. These equations use intersection characteristics, such as vehicle and pedestrian volumes, lane geometry, and signal phasings, as inputs in estimating control delay. The analysis methodology for both signalized and unsignalized intersections are described below:

Signalized Intersections

The 2000 HCM method for signalized intersections evaluates average control delays and then assign an LOS. Control delay is defined as the delay associated with deceleration, stopping, moving up in the queue, and acceleration experienced by drivers at an intersection. **Table 1** provides descriptions of various LOS and the corresponding ranges of delays for signalized intersections.

Unsignalized Intersections

For unsignalized intersection, the 2000 HCM method calculates delay for movements that are controlled by a stop sign or that must yield the right-of-way. The movement or approach with the highest delay is reported. The LOS ranges for unsignalized intersections are shown in **Table 1**. They are lower than the delay ranges for signalized intersections because drivers generally tolerate more delay at signals.

TABLE 1
INTERSECTION LEVEL OF SERVICE DEFINITIONS

Unsignalized Intersections		Level of Service Grade	Signalized Intersections	
Description	Average Total Vehicle Delay (Seconds)		Average Control Vehicle Delay (Seconds)	Description
No delay for stop-controlled approaches.	≤10.0	A	≤10.0	Free Flow or Insignificant Delays: Operations with very low delay, when signal progression is extremely favorable and most vehicles arrive during the green light phase. Most vehicles do not stop at all.
Operations with minor delay.	>10.0 and ≤15.0	B	>10.0 and ≤20.0	Stable Operation or Minimal Delays: Generally occurs with good signal progression and/or short cycle lengths. More vehicles stop than with LOS A, causing higher levels of average delay. An occasional approach phase is fully utilized.
Operations with moderate delays.	>15.0 and ≤25.0	C	>20.0 and ≤35.0	Stable Operation or Acceptable Delays: Higher delays resulting from fair signal progression and/or longer cycle lengths. Drivers begin having to wait through more than one red light. Most drivers feel somewhat restricted.
Operations with increasingly unacceptable delays.	>25.0 and ≤35.0	D	>35.0 and ≤55.0	Approaching Unstable or Tolerable Delays: Influence of congestion becomes more noticeable. Longer delays result from unfavorable signal progression, long cycle lengths, or high volume to capacity ratios. Many vehicles stop. Drivers may have to wait through more than one red light. Queues may develop, but dissipate rapidly, without excessive delays.
Operations with high delays, and long queues.	>35.0 and ≤50.0	E	>55.0 and ≤80.0	Unstable Operation or Significant Delays: Considered to be the limit of acceptable delay. High delays indicate poor signal progression, long cycle lengths and high volume to capacity ratios. Individual cycle failures are frequent occurrences. Vehicles may wait through several signal cycles. Long queues form upstream from intersection.
Operations with extreme congestion, and with very high delays and long queues unacceptable to most drivers.	>50.0	F	>80.0	Forced Flow or Excessive Delays: Occurs with oversaturation when flows exceed the intersection capacity. Represents jammed conditions. Many cycle failures. Queues may block upstream intersections.

Source: Highway Capacity Manual, Transportation Research Board, 2000.

3. Existing Conditions

Fehr & Peers conducted peak period automobile intersection turning movement counts, as well as pedestrian, bicycle and truck counts from 6:00 AM to 9:00 AM and from 4:00 PM to 6:00 PM on Tuesday, September 20, 2011, at all study intersections, while the Chevron Facility was operating under normal conditions.

Based on the collected counts, the weekday morning peak hour occurs from 7:15 to 8:15 AM and the evening peak hour occurs from 4:30 to 5:30 PM. **Figure 1** shows the existing intersection peak hour turning movements, intersection lane configurations and traffic controls. **Appendix A** provides the detailed count sheets.

Table 2 summarizes the intersection operation analysis results based on the traffic volumes, lane configurations, and traffic controls presented on Figure 1. **Appendix B** provides detailed intersection LOS calculation worksheets.

The City of Richmond General Plan classifies Richmond Parkway and Castro Street as Routes of Regional Significance.¹ Per West Contra Costa County Transportation Advisory Committee (WCCTAC) and the City of Richmond, signalized and unsignalized intersections on Routes of Regional Significance are considered to function at acceptable conditions if they operate at LOS D or better.² As shown in Table 2, all study intersections operate at LOS D or better during both AM and PM peak hours. These acceptable operations were confirmed by field observations.

¹ As described in the City of Richmond General Plan, routes of regional significance are roadways that (1) connect to a regional highway/transit facility; (2) carry significant amount of traffic; (3) cross County boundaries; and/or (4) connect more than one region of the County.

² The West Contra Costa County Transportation Advisory Committee's *West Contra Costa County Action Plan 2009 Update* (July 2009) establishes a Multi-Modal Traffic Service Objective of LOS D or better for intersections on Routes of Regional Significance. The City of Richmond General Plan policies state that LOS standards on routes of regional significance shall comply with WCCTAC's Action Plan.

**TABLE 2
EXISTING (2011) CONDITIONS
INTERSECTION LOS SUMMARY**

#	Intersection	Traffic Control ¹	AM Peak Hour		PM Peak Hour	
			Delay ²	LOS	Delay ²	LOS
1.	Chevron Way/Marine Street	AWSC	5.7	A	8.5	A
2.	Castro Street/Tewksbury Avenue	AWSC	8.3	A	9.3	A
3.	Marine Street/I-580 Eastbound Ramps	Signal	1.9	A	17.5	B
4.	Castro Street/I-580 Eastbound Ramps	Signal	17.5	B	50.9	D

4. Project Traffic Characteristics

Based on information provided by Chevron, the following are the primary sources of traffic generation during Project construction:

- **Facility Operations:** Normal day-to-day operations of the Facility, which will continue through the duration of Project construction. Existing Facility operations traffic is part of the Existing Conditions previously discussed. Changes to operations-related traffic generation, following Project construction, would be minor, as described below.
- **Project Construction:** Construction worker and truck Traffic associated with Project construction, which includes the construction of Hydrogen Plant Replacement, Sulfur Removal Improvements, Hydrogen Plant tie-ins, and Project Design Features.
- **Other Projects:** Construction worker and truck Traffic associated with other construction projects that would coincide with Project construction. This includes the Long Wharf

Maintenance and Efficiency Project, the Storage Tank Replacement Project, and other on-site projects and the Hensley Street and Kelham Warehouse Projects, both located east of Castro Street.

- **Periodic Facility Maintenance:** Facility maintenance activities, including shutdowns for maintenance of major Facility components ("Major Turnarounds"), which are anticipated to occur during Project construction;

This analysis evaluates the impacts associated with both Project construction and changes to Facility operations resulting from the Project construction. This analysis considers post-Project operations-related traffic generation as a potential cumulative impact in relation to past, present and reasonably foreseeable future projects. In addition, cumulative Project impacts associated with Other Projects and Major Turnarounds are also addressed.

The following scenarios are considered:

- Baseline (2016) No Project Conditions
- Baseline (2016) Plus Project Construction Conditions
- Baseline (2016) Plus Project Construction Plus Other Projects Construction Conditions
- Baseline (2016) Plus Project Construction Plus Other Projects Construction Plus Major Facility Turnaround Conditions
- Cumulative (2030) Conditions (assuming Facility operations, and changes to existing operations-related traffic generation, following Project construction).

For the Cumulative (2030) conditions, the Project would be in its operational phase (i.e., construction of its components would have been completed). The year 2030 was selected for the cumulative analysis due to the availability of traffic projections for that year from regional transportation authorities, and that the Project would have been fully operational for many years as of that time, and because this 2030 projection includes regional growth factors by expert agencies that are considered representative of long-term conditions. Specifically, the 2006 *Contra Costa Transportation Authority Travel Demand Forecasting Model* (CCTA Model) was used to forecast 2030 conditions. The CCTA Model forecasts include the most up-to-date information regarding City and County land use and transportation improvement information for both Contra Costa and Alameda Counties and also the greater Bay Area. The CCTA Model uses Association of Bay Area Governments (ABAG) *Projections 2009* for land use and employment. The City of

Richmond Preferred General Plan Alternative land use assumptions were used in the CCTA model to more accurately reflect expected growth in Richmond.

Operation of the Facility following Project construction would result in 29 new employees and generate about 94 new daily one-way truck trips because of increased import and export of materials to and from the Facility, which corresponds to 100 percent Facility utilization.

Trip Generation

Trip generation refers to the process of estimating the amount of vehicular traffic a project would add to the roadway network. The automobile traffic generated by the Project (and Other Projects, and Major Facility Turnarounds) was estimated based on data provided by Chevron. These estimates include both construction-related passenger car and truck trips. Truck trips were converted to Passenger Car Equivalents (PCE)³ to more accurately reflect the potential impacts of trucks on traffic flow. **Table 3** summarizes and **Appendix C** provides more detailed data on the estimated increase in daily traffic during the construction period. The table includes estimates not only for Project construction traffic, but also estimates for trip generation associated with Other Projects and Major Turnarounds, and to be conservative assumes these activities will coincide as Project construction. Major Turnarounds, in particular, can be scheduled at various times of the year, but for analytical purposes it has been assumed that a Major Turnaround could occur in the first quarter of 2016 (when Project construction traffic is estimated to be at its highest level).

Table 4 presents the AM and PM peak hour traffic generation estimates for the peak construction period of the Project, and the Other Projects, and the Major Turnaround that would coincide with the planned Project construction. Peak construction activity is expected to occur during the first quarter of 2016, when the Project, the Other Project, and the Major Turnaround combined are estimated to generate 7,503 trips on a typical day, 1,878 trips during the AM peak hour, and 1,743 trips during the PM peak hour.

³ Passenger-car equivalent (PCE) represents the number of passenger cars displaced by each truck in the traffic stream. One truck is the equivalent of two passenger cars for this analysis.

Total Volumes	1,803	1,839	1,783	1,737	7,503	3,691	3,071	2,567	714	724	724	668

¹ All vehicle and truck trips are shown as one-way trips per day. A round trip equals two trips. See Appendix C, for a breakdown of estimated daily traffic associated with separate individual projects.

² Miscellaneous construction support include lunch wagons, fueling, parts runs, etc.

³ Construction related trips (either vehicle or PCE) equals ONLY Project traffic. This is the basis for traffic impact evaluations and is shown **reversed** above.

⁴ Major turnarounds do not result from the Modernization Project and are shown here to provide an idea of total variability in Facility traffic. Totals reflect peak periods, and therefore are not at these levels for the entire quarter. Estimated durations of turnarounds vary from 18 to 38 days per turnaround. Turnaround schedules are subject to change (estimated traffic is based on Richmond Facility Long Range Shut Down Schedule, as of January 29, 2007). This analysis assumes that peak turnaround would coincide with peak activity generated by the Project Construction and Other Projects.

⁵ Passenger Car Equivalent (PCE) factor of 2.0 used per HCM 2000.

Source: Data provided by Chevron and summarized by Fehr & Peers, 2014.

TABLE 4
CHEVRON RICHMOND FACILITY CONSTRUCTION TRAFFIC ESTIMATES
(PEAK CONSTRUCTION ACTIVITY, FIRST QUARTER 2016)

Project	Type	Daily	AM Peak Hour (vehicle/hour)		PM Peak Hour (vehicle/hour)	
			In	Out	In	Out

Total Trips	Vehicle	6,965	1,743	0	0	1,743
	Trucks	538	135	0	0	0
	Total	7,503	1,878	0	0	1,743

¹ Peak construction activity during the first quarter of 2016, based on Chevron Construction Traffic Estimates (see Table 3). All trips are presented in PCEs.

² For peak hour trip generation, assume all inbound trips occur during the AM peak hour and all outbound trips occur during the PM peak hour, as shown:

- Half of the vehicle trips arrive at 6:00 AM for a 10-hour shift, departing at 4:00 PM.
- Half of the vehicle trips arrive at 7:00 AM for a 10-hour shift, departing at 5:00 PM.
- Assume all trucks are inbound in the AM and outbound in the PM.
- Assume half trucks arrive at 7:00 AM and depart at 3:00 PM; half arrive at 6:00 AM and depart at 2:00 PM. (Therefore, no trucks during the PM peak hour analysis period.)

Source: Data provided by Chevron and summarized by Fehr & Peers, 2014.

Trip Distribution

The trip distribution process estimates how the vehicle trips generated by a project site would distribute across the roadway network. The trip distribution of the construction-related vehicle trips was based on current observations at the Chevron Richmond Facility and a previous study (*Cleaner Fuels Project Circulation Analysis*). **Table 5** summarizes the trip distribution of the construction-related traffic. Both passenger vehicles and trucks generated by the Project are expected to depart and arrive from the following routes:

- North: to and from Richmond Parkway
- South: to and from I-580

TABLE 5 TRIP DISTRIBUTION CONSTRUCTION TRAFFIC		
Construction Trips	North	South
Passenger Vehicles	20%	80%
Trucks	80%	20%
Source: Fehr & Peers, 2014.		

Trip Assignment

The AM and PM peak hour peak construction-generated trip generation estimates were applied to the distribution paths described above, and the construction period trips were assigned to Gates 91 and 31, with the majority of the trips to/from Gate 91. The assigned Project construction trips were added to AM and PM peak hour volumes under the Baseline (2016) No Project Conditions to estimate the Baseline (2016) with-Project traffic volumes and to determine Project-specific construction impacts to study intersections.

5. Baseline (2016) No Project Conditions

The year 2016 was selected for the analysis of construction traffic impacts because construction traffic is expected to peak during the first quarter of 2016 (See Table 3). Intersection volumes in 2016 were interpolated using the 2011 measured traffic volumes and forecast growth rates developed using the Contra Costa County Transportation Authority Travel Demand Model (CCTA Model), as described in more detail below, to calculate the adjusted traffic Baseline. The impact

of the Project construction was estimated by evaluating how intersection LOS would change with the addition of construction-related traffic to this Baseline.

Although renovation work is currently underway on I-580 between the Chevron Facility and Richmond-San Rafael Bridge, this renovation work is anticipated to be completed prior to the expected start of Project construction in 2016. There are no other traffic-related improvements that are anticipated to change traffic conditions in 2016 relative to the conditions measured in 2011. Therefore, the intersection lane configurations and controls presented on Figure 1 continue to remain valid.

Project impacts are analyzed by comparing conditions with and without Project-generated traffic. The “without Project” (2016 Baseline) scenario represents reasonably-foreseeable conditions in 2016 without the addition of Project construction traffic. Current Facility operations will continue through the duration of Project construction, and existing traffic counts conducted at the study intersections and projected for Baseline conditions reflect the current operations. As described above, Project construction-generated traffic is expected to fluctuate during construction. The highest Project construction-generated traffic is expected in the first quarter of 2016. Therefore, the traffic impacts associated with the Project construction traffic were assessed under 2016 conditions.

Intersection volumes under Baseline conditions were interpolated using forecast growth rates developed using the Contra Costa County Transportation Authority Travel Demand Model (CCTA Model). CCTA Model was checked to ensure that it includes other planned and approved development projects within the City of Richmond expected to generate traffic in the year 2016 (see *Appendix 4.0, Cumulative Projects*), and it was determined that the CCTA model growth forecasts encompass the planned and approved development projects. **Figure 2** shows the intersection peak hour volumes under Baseline (2016) No Project conditions.

Table 6 shows the results of the intersection operations analysis for 2016 Baseline conditions. Under 2016 Baseline conditions (without Project), all study intersections would operate at acceptable LOS C or better during the AM peak hour. During the PM peak hour, eight of the 11 study intersections are estimated to operate at acceptable LOS D or better. The three intersections projected to operate at an unacceptable service (LOS E or F) during the PM peak hour are:

**TABLE 6
BASELINE (2016) NO PROJECT CONDITIONS

6. Traffic Impact Significance Criteria

As previously described, both WCCTAC and the City of Richmond consider intersections on Routes of Regional Significance to function at acceptable conditions if they operate at LOS D or better. This analysis identifies impacts by comparing peak hour intersection operations under Baseline (2016) Plus Project scenarios with Baseline (2016) No Project conditions. Consistent with WCCTAC and City of Richmond requirements, this analysis identifies an impact as significant if the Project would cause:

- A signalized intersection to deteriorate from LOS D or better to LOS E or LOS F.

- A signalized intersection where the level of service is LOS E, the Project would cause the average control delay to increase by more than five seconds or deteriorate to LOS F.
- A signalized intersection where the level of service is LOS F, the Project would cause the average control delay to increase by more than five seconds.
- An unsignalized intersection to operate at LOS F and after Project completion satisfy the Caltrans peak hour traffic volume signal warrant.

7. Baseline (2016) Plus Project Construction Conditions

The AM and PM peak hour traffic generated during the Project Construction (as shown in Table 4) were added to the Baseline (2016) No Project traffic volumes to estimate traffic volumes under Baseline (2016) Plus Project Construction conditions. **Figure 3** shows the intersection peak hour volumes under Baseline (2016) Plus Project Construction conditions.

Table 7 shows the results of the intersection operations analysis for the weekday AM and PM peak hours under Baseline (2016) Plus Project Construction conditions. Under Baseline (2016) Plus Project Construction conditions, all intersections would operate at acceptable LOS during the AM peak period. Eight of the 11 study intersections are forecast to operate at acceptable LOS D or better during the PM peak hour. The three intersections projected to operate at an unacceptable service (LOS E or F) during the PM peak are:

- Castro Street/I-580 Eastbound Ramps
- Castro Street/Redwood Way/I-580 Westbound Ramps
- Richmond Parkway/Gertrude Avenue

The Project impact at the Castro Street/I-580 Eastbound Ramps intersection is considered less-than-significant, because conditions would remain unchanged at LOS F, with average delay remaining the same.

Project Construction would result in two significant impacts which can be mitigated to less-than-significant levels. **Table 8** summarizes intersection operations under Baseline (2016) Plus Project Construction conditions with and without the mitigation measures. Both impacts and their mitigation measures are described below:

**TABLE 7
BASELINE (2016) PLUS PROJECT CONSTRUCTION CONDITIONS
INTERSECTION LOS SUMMARY**

#	Intersection	Traffic Control ¹	AM Peak Hour		PM Peak Hour	
			Delay ²	LOS	Delay ²	LOS
1.	Chevron Way/Marine Street	AWSC	5.9	A	8.5	A
2.	Castro Street/Tewksbury Avenue	AWSC	8.7	A	9.6	A
3.	Marine Street/I-580 Eastbound Ramps	Signal	2.5	A	35.0	C

¹ AWSC = all-way stop-controlled intersection; Signal = traffic signal-controlled intersection.

² Average overall intersection control delay (seconds per vehicle) reported for signalized and all-way stop-controlled intersections.

Source: Fehr & Peers, 2014.

Impact 1: Project construction-generated increases in traffic volumes would result in a significant impact during the PM peak hour at the signalized Castro Street/I-580 Westbound Ramps intersection. This impact would be mitigated to a less-than-significant level by implementation of Mitigation Measure 1.

Project construction-related traffic is projected to add a substantial amount of traffic to the critical movements of the Castro Street/I-580 Westbound Ramps intersection, which would result in a significant worsening of its operating conditions (from LOS E to LOS F during the PM peak hour)

Mitigation Measure 1: Implement the following measures at the Castro Street/I-580 Westbound Ramps intersection:

TABLE 8 BASELINE (2016) PLUS PROJECT CONSTRUCTION MITIGATED CONDITIONS INTERSECTION LOS SUMMARY									
#	Intersection	Traffic Control ¹	Peak Hour	Baseline No Project		Baseline Plus Project Construction		Baseline Plus Project Construction Mitigated	
				Delay ²	LOS	Delay ²	LOS	Delay ²	LOS
6.	Castro Street/I-580 Westbound Ramps	Signal	AM	25.3	C	29.5	C	29.5	C
			PM	74.8	E	94.7	F	49.1	D
11.	Richmond Parkway/ Gertrude Avenue	Signal	AM	21.1	C	29.6	C	29.6	C
			PM	85.5	F	99.5	F	65.1	E
Bold type indicates significant impact.

² Average overall intersection control delay (seconds per vehicle) reported for signalized and all-way stop-controlled intersections.									
Source: Fehr & Peers, 2014.									

- Chevron shall work with the City of Richmond's Director of Public Works Department (or the Director's designated representative) and Caltrans to provide modified traffic control during peak arrival and departure times in the PM peak hour. The modified traffic control shall be accomplished by one or more of the following methods: (1) posting a technician at the intersection to manually operate signal controls (using the police key feature of standard traffic signal controllers), (2) programming an alternate signal timing plan that would be in operation during specified peak commute periods, and/or (3) posting traffic control officers at the intersection to manually control traffic movements. Chevron shall pay the full cost of this measure, including costs for sheriff's deputies or other law enforcement personnel to provide the traffic control under above-cited methods (1) or (3).

Implementation of Mitigation Measure 1 would improve intersection operating conditions to LOS D during the PM peak hour, resulting in a less than significant impact after mitigation.

Impact 2: Project construction-generated increases in traffic volumes would result in a significant impact during the PM peak hour at the signalized Richmond Parkway/

Gertrude Avenue intersection. This impact would be mitigated to a less-than-significant level by implementation of Mitigation Measure 2.

Project construction-related traffic is projected to add a substantial amount of traffic to the critical movements of the Richmond Parkway/Gertrude Avenue intersection, which would result in a significant worsening of its operating conditions. (The intersection would continue to operate at LOS F during the PM peak hour with the Project increasing average intersection delay by about 14 seconds).

Mitigation Measure 2: Implement the following measures at the Richmond Parkway/Gertrude Avenue intersection:

- Chevron shall work with the City of Richmond's Director of Public Works Department (or the Director's designated representative) to provide modified traffic control during peak arrival and departure times in the PM peak hour. The modified traffic control shall be accomplished by one or more of the following methods: (1) posting a technician at the intersection to manually operate signal controls (using the police key feature of standard traffic signal controllers), (2) programming an alternate signal timing plan that would be in operation during specified peak commute periods, and/or (3) posting traffic control officers at the intersection to manually control traffic movements. Chevron shall pay the full cost of this measure, including costs for sheriff's deputies or other law enforcement personnel to provide the traffic control under above-cited methods (1) or (3).
- During the peak congestion periods, through the use of traffic cones (and flaggers as needed), Chevron shall reconfigure the southbound (Richmond Parkway) approach to the intersection to provide one shared left-through lane, one through lane, and one shared right-through lane.

Implementation of Mitigation Measure 2 would improve intersection operating conditions to LOS E during the PM peak hour, resulting in a less than significant impact.

In addition to the above mitigation measures, implementation of one or more of the following strategies would also reduce the constructed related traffic during Project Construction and reduce the magnitude of the Project impact at the study intersections during the AM and PM peak hours:

- Stagger the hours of operation of the craft labor so that the construction-related traffic would be distributed over the peak and non-peak hours of traffic operation.
- Promote the use of car-sharing by the craft labor.
- Coordinate the construction schedule between the Project, construction of the Other Projects, and the Major Facility Turnaround, to minimize combined traffic generation on any single day.

8. Baseline (2016) Plus Project Construction Plus Other Projects Conditions

This section addresses potential impacts of the Project Construction combined with construction of Other Projects that would occur at the same time. As shown in Table 3, Project Construction and Other Projects combined are expected to peak during the first quarter of 2016. The AM and PM peak hour traffic generated by the Other Projects (as shown in Table 4) were added to the Baseline (2016) Plus Project Construction traffic volumes to estimate traffic volumes under Baseline (2016) Plus Project Construction Plus Other Projects conditions. **Figure 4** shows the intersection peak hour volumes under Baseline (2016) Plus Project Construction Plus Other Projects conditions.

Table 9 shows the results of the intersection operations analysis for the weekday AM and PM peak hours under Baseline (2016) Plus Project Construction Plus Other Projects conditions. Under Baseline (2016) Plus Project Construction Plus Other Projects conditions, all intersections would operate at acceptable LOS during the AM peak period. Seven of the 11 study intersections are forecast to operate at acceptable LOS D or better during the PM peak hour. The four intersections projected to operate at an unacceptable service (LOS E or F) during the PM peak are:

- Castro Street/I-580 Eastbound Ramps
- Castro Street/Redwood Way/I-580 Westbound Ramps
- Castro Street/Hensley Street
- Richmond Parkway/Gertrude Avenue

The impact at the Castro Street/I-580 Eastbound Ramps intersection is considered less-than-significant, because conditions would remain unchanged at LOS F, with average delay remaining the same.

**TABLE 9

Project Construction and Other Projects combined would result in three significant impacts which can be mitigated to less-than-significant levels. **Table 10** summarizes intersection operations under Baseline (2016) Plus Project Construction Plus Other Projects conditions with and without the mitigation measures. The three impacts and their mitigation measures are described below:

Impact 3: Project Construction plus Other Projects-generated increases in traffic volumes would result in a significant impact during the PM peak hour at the signalized Castro Street/I-580 Westbound Ramps intersection. This impact would be mitigated to a less-than-significant level by implementation of Mitigation 3.

Bold type indicates significant impact.

¹ AWSC = all-way stop-controlled intersection; Signal = traffic signal-controlled intersection.

² Average overall intersection control delay (seconds per vehicle) reported for signalized and all-way stop-controlled intersections.

Source: Fehr & Peers, 2014.

Project Construction-related traffic combined with Other Project construction-related traffic is projected to add a substantial amount of traffic to the critical movements of the Castro Street/I-580 Westbound Ramps intersection, which would result in a significant worsening of its operating conditions (from LOS E to LOS F during the PM peak hour).

Mitigation Measure 3: Implementation of Mitigation Measure 1 would improve intersection operating conditions to LOS E during the PM peak hour.

Impact 4: Project Construction plus Other Projects-generated increases in traffic volumes would result in a significant impact during the PM peak hour at the signalized Castro Street/Hensley Street intersection. This impact would be mitigated to a less-than-significant level by implementation of Mitigation Measure 4.

Project Construction-related traffic combined with Other Project construction-related traffic is projected to add a substantial amount of traffic to the critical movements of the Castro Street/Hensley Street intersection, which would result in a significant worsening of its operating conditions (From LOS C to LOS F during the PM peak hour).

Mitigation Measure 4: Implement the following measures at the Castro Street/Hensley Street intersection:

- Chevron shall work with the City of Richmond's Director of Public Works Department (or the Director's designated representative) to provide modified traffic control during peak arrival and departure times in the PM peak hour. The modified traffic control shall be accomplished by one or more of the following methods: (1) posting a technician at the intersection to manually operate signal controls (using the police key feature of standard traffic signal controllers), (2) programming an alternate signal timing plan that would be in operation during specified peak commute periods, and/or (3) posting traffic control officers at the intersection to manually control traffic movements. Chevron shall pay the full cost of this measure, including costs for sheriff's deputies or other law enforcement personnel to provide the traffic control under above-cited methods (1) or (3).

Implementation of Mitigation Measure 4 would improve intersection operating conditions to LOS C during the PM peak hour, resulting in a less-than-significant impact.

Impact 5: Project Construction plus Other Projects-generated increases in traffic volumes would result in a significant impact during the PM peak hour at the signalized Richmond Parkway/Gertrude Avenue intersection. This impact would be mitigated to a less-than-significant level by implementation of Mitigation Measure 5.

Project construction-related traffic combined with Other Project construction-related traffic is projected to add a substantial amount of traffic to the critical movements of the Richmond Parkway/Gertrude Avenue intersection, which would result in a significant worsening of its operating conditions (The intersection would continue to operate at LOS F during the PM peak hour with the Project increasing average intersection delay by about 23 seconds).

Mitigation Measure 5: Implementation of Mitigation Measure 2 would improve intersection operating conditions to LOS E during the PM peak hour.

9. Baseline (2016) Plus Project Construction Plus Other Projects Plus Major Turnaround Conditions

This section addresses potential impacts of the Project Construction combined with construction of Other Projects and a Major Turnaround that would occur at the same time. This analysis assumes that a Major Turnaround would occur during the first quarter of 2016, when the traffic generated by the combined Project Construction and Other Projects would peak. The AM and PM peak hour traffic generated by the Major Turnaround (as shown in Table 4) were added to the Baseline (2016) Plus Project Construction Plus Other Projects traffic volumes to estimate traffic volumes under Baseline (2016) Plus Project Construction Plus Other Projects Plus Major Turnaround conditions. **Figure 5** shows the intersection peak hour volumes under Baseline (2016) Plus Project Construction Plus Other Projects Plus Major Turnaround conditions.

Table 11 shows the results of the intersection operations analysis for the weekday AM and PM peak hours under Baseline (2016) Plus Project Construction Plus Other Projects Plus Major Turnaround conditions. Under Baseline (2016) Plus Project Construction Plus Other Projects Plus Major Turnaround conditions, nine of the 11 study intersections during the AM peak hour and six of the 11 study intersections during the PM peak hour would operate at acceptable LOS D or better. The four intersections projected to operate at an unacceptable level (LOS E or F) during either or both peak hours are listed below:

- Castro Street/I-580 Eastbound Ramps (PM only)
- Castro Street/Redwood Way/I-580 Westbound Ramps (PM only)
- Castro Street/General Chemical Access (AM and PM)
- Castro Street/Hensley Street (PM only)
- Richmond Parkway/Gertrude Avenue (AM and PM)

The impact at the Castro Street/I-580 Eastbound Ramps intersection is considered less-than-significant, because conditions would remain unchanged at LOS F, with average delay remaining the same.

TABLE 11
BASELINE (2016) PLUS PROJECT CONSTRUCTION
PLUS OTHER PROJECTS PLUS MAJOR TURNAROUND CONDITIONS
INTERSECTION LOS SUMMARY

#	Intersection	Traffic Control ¹	AM Peak Hour		PM Peak Hour	
			Delay ²	LOS	Delay ²	LOS

Project Construction, Other Projects, and a Major Turnaround combined would result in four significant impacts which can be mitigated to less-than-significant levels. **Table 12** summarizes intersection operations under Baseline (2016) Plus Project Construction Plus Other Projects Plus Major Turnaround conditions with and without the mitigation measures. The four impacts and their mitigation measures are described below:

Impact 6: Project Construction plus Other Projects plus Major Turnaround-generated increases in traffic volumes would result in a significant impact during the PM peak hour traffic operations at the signalized Castro Street/I-580 Westbound Ramps intersection. This impact would be mitigated to a less-than-significant level by implementation of Mitigation Measure 6.

² Average overall intersection control delay (seconds per vehicle) reported for signalized and all-way stop-controlled intersections.									
Source: Fehr & Peers, 2014.									

Project Construction-related traffic combined with Other Project construction and Major Turnaround-related traffic is projected to add a substantial amount of traffic to the critical movements of the Castro Street/I-580 Westbound Ramps intersection, which would result in a significant worsening of its operating conditions (from LOS E to LOS F during the PM peak hour).

Mitigation Measure 6: Implementation of Mitigation Measure 1 would improve intersection operating conditions to LOS E during the PM peak hour.

Impact 7: Project Construction plus Other Projects plus Major Turnaround-generated increases in traffic volumes would result in a significant impact during AM and

PM peak hours at the signalized Castro Street/General Chemical Access (Gate 91) intersection. This impact would be mitigated to a less-than-significant level by implementation of Mitigation Measure 7.

Project construction-related traffic combined with Other Project construction and Major Turnaround-related traffic is projected to add a substantial amount of traffic to the critical movements of the Castro Street/General Chemical Access (Gate 91) intersection, which would result in a significant worsening of its operating conditions (from LOS A during the AM peak hour and LOS during the PM peak hour to LOS F during both AM and PM peak hours).

Mitigation Measure 7: Implement the following measures at the intersection of Castro Street/General Chemical Access (Gate 91) intersection:

- During the AM peak period, through the use of traffic cones (and flaggers as needed), Chevron shall reconfigure the northbound (Castro Street) approach to the intersection to provide two left-turn lanes, and one shared right-through lane. The inbound approach on General Chemical Access would also be reconfigured to provide two receiving lanes.
- During the PM peak period, through the use of traffic cones (and flaggers as needed), Chevron shall reconfigure the eastbound (General Chemical Access) approach to the intersection to provide two exclusive right-turn lanes, and one exclusive left-turn lane.
- Chevron shall work with the City of Richmond's Director of Public Works Department (or the Director's designated representative) to provide modified traffic control during peak arrival and departure times in the AM and PM peak hours. The modified traffic control shall be accomplished by one or more of the following methods: (1) posting a technician at the intersection to manually operate signal controls (using the police key feature of standard traffic signal controllers), (2) programming an alternate signal timing plan that would be in operation during specified peak commute periods, and/or (3) posting traffic control officers at the intersection to manually control traffic movements. Chevron shall pay the full cost of this measure, including costs for sheriff's deputies or other law enforcement personnel to provide the traffic control under above-cited methods (1) or (3).

Implementation of Mitigation Measure 7 would improve intersection operating conditions to LOS D during both AM and PM peak hours.

Impact 8: Project Construction plus Other Projects Plus Major Turnaround-generated increases in traffic volumes would result in a significant impact during the PM peak hour at the signalized Castro Street/Hensley Street intersection. This impact would be mitigated to a less-than-significant level by implementation of Mitigation Measure 8.

Project construction-related traffic combined with Other Project construction and Major Turnaround-related traffic is projected to add a substantial amount of traffic to the critical movements of the Castro Street/Hensley Street intersection, which would result in a significant worsening of its operating conditions (From LOS C to LOS F during the PM peak hour).

Mitigation Measure 8: Implementation of Mitigation Measure 4 would improve intersection operating conditions to LOS D during the PM peak hour, resulting in a less-than-significant impact.

Impact 9: Project Construction Plus Other Projects Plus Major Turnaround-generated increases in traffic volumes would result in a significant impact during AM and PM peak hours at the signalized Richmond Parkway/Gertrude Avenue intersection. This impact would be mitigated to a less-than-significant level by implementation of Mitigation Measure 9.

Project construction-related traffic combined with Other Project construction and Major Turnaround related traffic is projected to add a substantial amount of traffic to the critical movements of the Richmond Parkway/Gertrude Avenue intersection, which would result in a significant worsening of its operating conditions (from LOS C to LOS E during the AM peak hour. The intersection would continue to operate at LOS F during the PM peak hour with the Project increasing average intersection delay by about 34 seconds).

Mitigation Measure 9: Implementation of Mitigation Measure 2 would improve intersection operating conditions to LOS B during the AM peak hour and LOS E during the PM peak hour.

10. Cumulative (2030) Conditions

The Cumulative 2030 scenario, which is defined by the horizon year of the CCTA countywide travel demand model, was assessed to determine long-term traffic impacts associated with buildout conditions in the area. The locations and sizes of the major development projects envisioned in the county and cities' General Plans have been programmed into the CCTA Model, which reflects regional growth based on projections that are consistent with forecasts by ABAG. In the vicinity of the Project, the Cumulative (2030) scenario accounts for the completion and occupancy of the proposed Hensley Street and Kelham Warehouse Projects.

Traffic operating conditions on project-used roadways in 2030 would be adversely affected by growth in population and employment in the area. **Table 13** presents intersection operations for the weekday AM and PM peak hours under Cumulative 2030 conditions. Under Cumulative (2030) conditions, 3 of the 11 study intersections are forecast to operate at acceptable LOS D or better during both peak hours. The eight intersections projected to operate at an unacceptable level of service (LOS E or F) during one or both peak hour are:

- Marine Street/I-580 Eastbound Ramps (LOS F in PM peak hour)
- Castro Street/I-580 Eastbound Ramps (LOS F in PM peak hour)
- Castro Street/I-580 Westbound Ramps (LOS E in the AM peak hour and LOS F in the PM peak hour)
- Castro Street/Mills Street (LOS E in PM peak hour)
- Castro Street/General Chemical Access (LOS F in PM peak hour)
- Castro Street/Hensley Street (LOS F in the PM peak hour).
- Richmond Parkway/Hensley Street (LOS E in the AM peak hour).
- Richmond Parkway/Gertrude Avenue (LOS F in the PM peak hour).

For the Cumulative (2030) scenario, the Project would be in its operational phase (i.e., construction of its components would have already been completed).

**TABLE 13
CUMULATIVE (2030) CONDITIONS
INTERSECTION LOS SUMMARY**

#	Intersection	Traffic Control ¹	AM Peak Hour		PM Peak Hour	
			Delay ²	LOS	Delay ²	LOS

Table 14 presents the new trips that would be generated by the Chevron Facility after completion of construction assuming 100 percent facility utilization. Operation of the Facility following Project construction would generate about 94 new daily one-way truck trips (corresponding to 188 PCE trips) because of increased import and export of materials to and from the Facility. Although, the additional truck trips would be spread over the operating hours of the day and are expected to occur primarily during off-peak traffic hours, this analysis conservatively assumes that they will be spread uniformly throughout the day. Facility permanent employment levels would increase by 29 employees, resulting in a maximum of 58 new daily commuter trips.

TABLE 14 CHEVRON RICHMOND FACILITY PROJECT OPERATIONS TRAFFIC ESTIMATE						
Project	Type	Daily	AM Peak Hour (vehicle/hour)		PM Peak Hour (vehicle/hour)	
			In	Out	In	Out
Project Operations (100% utilization)	Workers ¹	58	29	0	0	29
	Trucks ²	188	10	9	9	10
	Total	246	39	9	9	39
¹ Trips generated by 29 net new worker trips. Half arrive during the AM peak hour and half depart during the PM peak hour. ² Truck trips in PCEs. Trucks arrive and depart uniformly throughout a typical 10-hour weekday. Source: Chevron, Fehr & Peers, 2014.						

The Project's contribution to the unacceptable levels of service described above were determined on the basis of reasonably-conservative assumptions that 48 new PCE trips would occur during the peak traffic hours. The Project contribution would be less than one percent and that level of additional vehicles on area roadways during peak traffic hours would be within the typical fluctuation in day-to-day traffic volumes and would not be noticed by most drivers; therefore, its effect on traffic operating conditions would not be cumulatively considerable.

11. Threshold Analysis

This section identifies the following for each of the intersections identified as having a significant impact:

- The peak hour traffic volume threshold that triggers the significant impact.
- The peak hour traffic volume threshold that the recommended mitigation measure would no longer be sufficient.

Table 15 summarizes the thresholds for the identified impacts and mitigation measures. For each impacted intersection, the table shows the additional volume generated by the Project Construction (by itself or combined with Other Projects and the Major Turnaround) that would trigger an impact and the range where the recommended mitigation measures would continue to mitigate the identified impact to a less-than-significant level.

**TABLE 15

Total Proposed Project Construction PCE Volumes³	0	0	0	0	2,144	2,018	1,418	894	678	688	688	688	
Total Volumes	1,803	1,839	1,783	1,737	7,503	3,691	3,091	2,567	714	724	724	688	

1. All vehicle and truck trips are shown as one-way trips per day. A round trip equals two trips.

2. Miscellaneous construction support include lunch wagons, fueling, parts runs, etc.

3. Construction related trips (either vehicle or PCE) equals ONLY Project traffic. **This is the basis for traffic impact evaluations and is shown reversed above.**

4. Major Turnarounds are shown to provide an idea of total variability in refinery traffic and do not result from the Modernization Project. Totals reflect peak periods, and therefore are not at these levels for the entire quarter. Estimated durations of turnarounds vary from 18 to 38 days per turnaround. 2010-2012 period shows selected peak future quarters with projected turnaround activity and Renewal Project in operation. Turnaround schedules are subject to change (estimated traffic is based on Richmond Refinery Long Range Shut Down Schedule, as of January 29, 2007). This analysis assumes that peak turnaround would coincide with peak activity generated by the Project Construction and Other Projects.

5. Passenger Car Equivalent (PCE) factor of 2.0 used per HCM 2000.

APPENDIX 4.17

Water Supply Assessment

March 11, 2014

Lina Velasco, Senior Planner
City of Richmond
450 Civic Center Plaza
Richmond, CA 94804-1630

Re: Validation of Water Supply Assessment for the Richmond Refinery Modernization Project

Dear Ms. Velasco:

This letter is in response to your request dated February 11, 2014 for water agency consultation concerning the validation of a Water Supply Assessment (WSA) for the Richmond Refinery Modernization Project, formerly the Chevron Energy and Hydrogen Renewal Project. East Bay Municipal Utility District (EBMUD) appreciates the opportunity to provide this response.

On April 17, 2007, EBMUD received a request from the City of Richmond (City) for a WSA for the Chevron Energy and Hydrogen Renewal Project which consisted of modifying or replacing existing equipment and installing new refining equipment within the existing refinery footprint. Pursuant to the California Water Code, EBMUD approved the WSA and provided the City with a written response to the WSA on April 24, 2007 which was attached to your request.

The estimated demand for the Chevron Energy and Hydrogen Renewal Project in the approved WSA was about 12.7 million gallons per day (mgd). Per the City's current request, the water demand for the Richmond Refinery Modernization Project is estimated to be about 12.7 mgd. The projected water demand is based on current consumption rates, and a foreseeable increase in recycled water usage from the North Richmond Water Reclamation Plant (NRWRP) and the Richmond Advanced Recycled Expansion (RARE) Project and associated potable water usage.

EBMUD concludes that the WSA approved by EBMUD on April 24, 2007 is still valid and a second WSA is not required for the Richmond Refinery Modernization Project.

Please note that the current recycled water supply from the NRWRP and RARE Project is about 4.0 mgd and 3.5 mgd, respectively, which are consistent with the City's baseline average demands. EBMUD has future plans to expand the available supply from NRWRP by 1.0 mgd by 2025 and RARE by 0.5 mgd in 2020, which match the City's 100 percent utilization scenario with a total projection of 9.0 mgd of recycled water. The NRWRP and RARE Project and expansions are reflected in EBMUD's recycled water program goal and in the 2010 Urban Water Management Plan; the current schedule is based on available supply and funding options which could accelerate or delay implementation. EBMUD recommends that the City and Chevron
